EUROPEAN PHARMACOPOEIA 6th EDITION

published 16 July 2007

replaces the 5th Edition on 1 January 2008

Volumes 1 and 2 of this publication 6.0 constitute the 6th Edition of the European Pharmacopoeia. They will be complemented by **non-cumulative supplements** that are to be kept for the duration of the 6th Edition. 2 supplements will be published in 2007 and 3 supplements in each of the years 2008 and 2009. A cumulative list of reagents will be published in supplements 6.4 and 6.7.

If you are using the 6th Edition at any time later than 1 April 2008, make sure that you have all the published supplements and consult the index of the most recent supplement to ensure that you use the latest versions of the monographs and general chapters.

EUROPEAN PHARMACOPOEIA - ELECTRONIC VERSION

The 6th Edition is also available in an electronic format (CD-ROM and online version) containing all of the monographs and general chapters found in the printed version. With the publication of each supplement the electronic version is replaced by a new, fully updated, cumulative version.

In addition to the official English and French online versions, a Spanish online version is also available for the convenience of users.

PHARMEUROPA

Quarterly Forum Publication

Pharmeuropa contains preliminary drafts of all new and revised monographs proposed for inclusion in the European Pharmacopoeia and gives an opportunity for all interested parties to comment on the specifications before they are finalised. Pharmeuropa also contains information on the work programme and on certificates of suitability to monographs of the European Pharmacopoeia issued by the EDQM, and articles of general interest. Pharmeuropa is available on subscription from the EDQM. The subscription also includes Pharmeuropa Bio and Pharmeuropa Scientific Notes (containing scientific articles on pharmacopoeial matters). Pharmeuropa Online is also available as a complementary service for subscribers to the printed version of Pharmeuropa.

INTERNATIONAL HARMONISATION

See the information given in chapter *5.8. Pharmacopoeial Harmonisation*.

HELPDESK

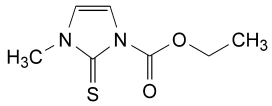
To send a question or to contact the EDQM, use the HELPDESK, accessible through the EDQM website (visit http://www.edqm.eu/site/page_521.php).

KNOWLEDGE

Consult KNOWLEDGE, the new free database at http://www.edqm.eu to obtain information on the work programme of the European Pharmacopoeia, the volume of Pharmeuropa and of the European Pharmacopoeia in which a text has been published, trade names of the reagents (for example, chromatography columns) that were used at the time of the elaboration of the monographs, the history of the revisions of a text since its publication in the 5th Edition, reference chromatograms, the list of reference standards used, and the list of certificates granted.

COMBISTATS

CombiStats is a computer program for the statistical analysis of data from biological assays in agreement with chapter *5.3* of the 6th Edition of the European Pharmacopoeia. For more information, visit the website (http://www.edqm.eu/combistats).



Version date of the text — **01/2008:0884** corrected 6.0

Text reference number

CARBIMAZOLE

Carbimazolum

Modification to be taken into account from the publication date of volume 6.0

CAS number — $C_7H_{10}N_2O_2S$ [22232-54-8] M_r 186.2

DEFINITION

Chemical name in accordance with IUPAC nomenclature rules — Ethyl 3-methyl-2-thioxo-2,3-dihydro-1*H*-imidazole-1-carboxylate.

Content: 98.0 per cent to 102.0 per cent (dried substance).

CHARACTERS

Appearance: white or yellowish-white, crystalline powder.

Solubility: slightly soluble in water, soluble in acetone and in ethanol (96 per cent).

Application of the first and second identification is defined in the General Notices (chapter 1) — *First identification: B.*

Second identification: A, C.

IDENTIFICATION

A. Melting point (*2.2.14*): 122 °C to 125 °C.

B. Infrared absorption spectrophotometry (*2.2.24*).

Preparation: discs.

Reference standard available from the Secretariat (see www.edqm.eu) — *Comparison*: *carbimazole CRS*.

C. Thin-layer chromatography (*2.2.27*).

Test solution. Dissolve 10 mg of the substance to be examined in *methylene chloride R* and dilute to 10 ml with the same solvent.

Reference solution. Dissolve 10 mg of *carbimazole CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent.

Plate: *TLC silica gel GF_{254} plate R*.

Reagents described in chapter 4 — *Mobile phase*: *acetone R*, *methylene chloride R* (20:80 *V/V*).

Application: 10 µl.

Development: over a path of 15 cm.

Further information available on www.edqm.eu (KNOWLEDGE) — *Drying*: in air for 30 min.

Detection: examine in ultraviolet light at 254 nm.

Results: the principal spot in the chromatogram obtained with the test solution is similar in position and size to the principal spot in the chromatogram obtained with the reference solution.

Reference to a general chapter — TESTS

Related substances. Liquid chromatography (*2.2.29*).

Line in the margin indicating where part of the text has been modified (technical modification) — *Test solution*. Dissolve 5.0 mg of the substance to be examined in 10.0 ml of a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R*. Use this solution within 5 min of preparation.

Reference solution (a). Dissolve 5 mg of *thiamazole R* and 0.10 g of *carbimazole CRS* in a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R* and dilute to 100.0 ml with the same mixture of solvents. Dilute 1.0 ml of this solution to 10.0 ml with a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R*.

Reference solution (b). Dissolve 5.0 mg of *thiamazole R* in a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R* and dilute to 10.0 ml with the same mixture of solvents. Dilute 1.0 ml of this solution to 100.0 ml with a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R*.

Column:

– *size*: *l* = 0.15 m, Ø = 3.9 mm,

– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase: *acetonitrile R*, *water R* (10:90 *V/V*).

Flow rate: 1 ml/min.

Detection: spectrophotometer at 254 nm.

Injection: 10 µl.

Run time: 1.5 times the retention time of carbimazole.

Retention time: carbimazole = about 6 min.

System suitability: reference solution (a):

– *resolution*: minimum 5.0 between the peaks due to impurity A and carbimazole.

Limits:

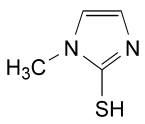
– *impurity A*: not more than 0.5 times the area of the principal peak in the chromatogram obtained with reference solution (b) (0.5 per cent),

– *unspecified impurities*: for each impurity, not more than 0.1 times the area of the principal peak in the chromatogram obtained with reference solution (b) (0.10 per cent).

Loss on drying (*2.2.32*): maximum 0.5 per cent, determined on 1.000 g by drying in a desiccator over *diphosphorus pentoxide R* at a pressure not exceeding 0.7 kPa for 24 h.

Sulphated ash (*2.4.14*): maximum 0.1 per cent, determined on 1.0 g.

ASSAY



Dissolve 50.0 mg in *water R* and dilute to 500.0 ml with the same solvent. To 10.0 ml add 10 ml of *dilute hydrochloric acid R* and dilute to 100.0 ml with *water R*. Measure the absorbance (*2.2.25*) at the absorption maximum at 291 nm.

Calculate the content of $C_7H_{10}N_2O_2S$ taking the specific absorbance to be 557.

IMPURITIES

Specified impurities: A.

Other detectable impurities (the following substances would, if present at a sufficient level, be detected by one or other of the tests in the monograph. They are limited by the general acceptance criterion for other/unspecified impurities and/or by the general monograph *Substances for pharmaceutical use (2034)*. It is therefore not necessary to identify these impurities for demonstration of compliance. See also *5.10. Control of impurities in substances for pharmaceutical use): B.*

A. 1-methyl-1*H*-imidazole-2-thiol (thiamazole),

SPECIMEN

IMPORTANT NOTICE

GENERAL MONOGRAPHS

The European Pharmacopoeia contains a number of general monographs covering classes of products. These general monographs give requirements that are applicable to all products in the given class or, in some cases, to any product in the given class for which there is a specific monograph in the Pharmacopoeia (see *1. General Notices*, General monographs). Where no restriction on scope of a general monograph is given in a preamble, it is applicable to all products in the class defined, irrespective of whether there is an individual monograph for the product in the Pharmacopoeia.

Whenever a monograph is used, it is essential to ascertain whether there is a general monograph applicable to the product in question. The general monographs listed below are published in the section General Monographs (unless otherwise stated). This list is updated where necessary and republished in each Supplement.

Allergen products (1063)

Dosage Forms monographs
(published in the Dosage Forms section)

Essential oils (2098)

Extracts (0765)

Herbal drug preparations (1434)

Herbal drugs (1433)

Herbal drugs for homoeopathic preparations (2045)
(published in the Homoeopathic Preparations section)

Herbal teas (1435)

Homoeopathic preparations (1038)
(published in the Homoeopathic Preparations section)

Immunosera for human use, animal (0084)

Immunosera for veterinary use (0030)

Methods of preparation of homoeopathic stocks and potentisation (2371)
(published in the Homoeopathic Preparations section)

Monoclonal antibodies for human use (2031)

Mother tinctures for homoeopathic preparations (2029)
(published in the Homoeopathic Preparations section)

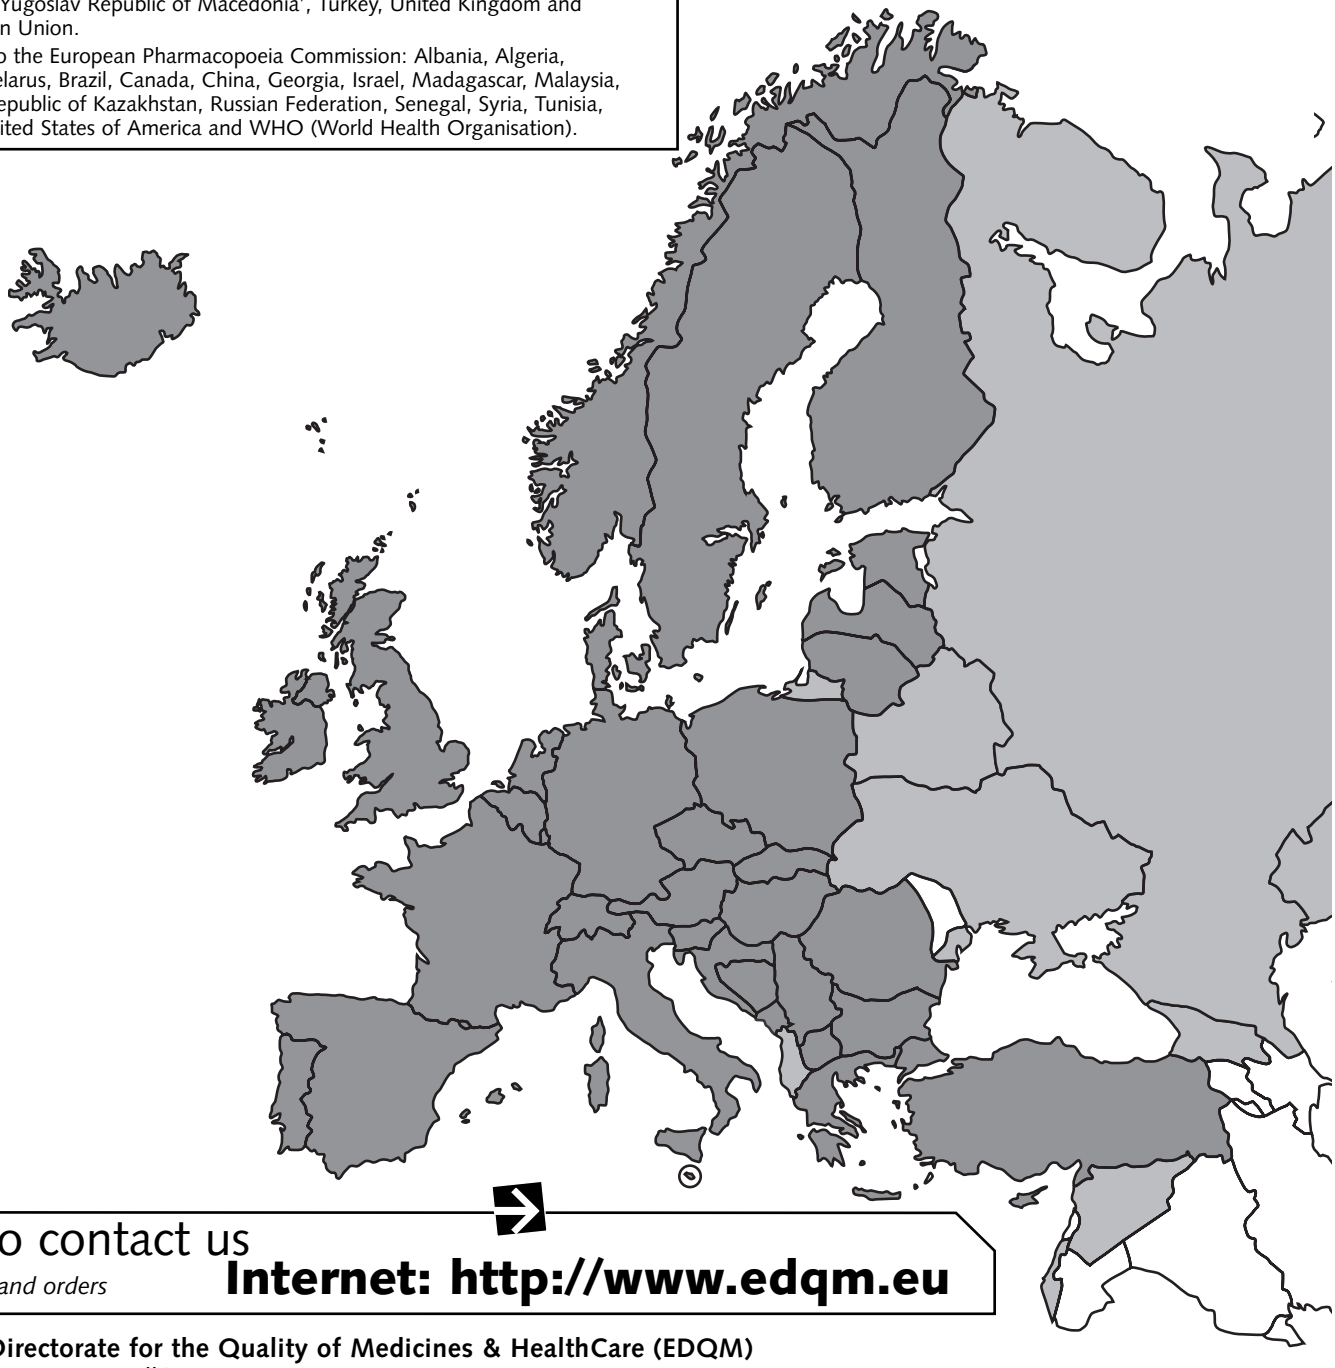
Products of fermentation (1468)

Products with risk of transmitting agents of animal spongiform encephalopathies (1483)

Radiopharmaceutical preparations (0125)

Recombinant DNA technology, products of (0784)

Substances for pharmaceutical use (2034)



Vaccines for human use (0153)

Vaccines for veterinary use (0062)

Vegetable fatty oils (1579)

Members of the European Pharmacopoeia Commission: Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Montenegro, Netherlands, Norway, Poland, Portugal, Romania, Serbia, Slovak Republic, Slovenia, Spain, Sweden, Switzerland, 'the former Yugoslav Republic of Macedonia', Turkey, United Kingdom and the European Union.

Observers to the European Pharmacopoeia Commission: Albania, Algeria, Australia, Belarus, Brazil, Canada, China, Georgia, Israel, Madagascar, Malaysia, Morocco, Republic of Kazakhstan, Russian Federation, Senegal, Syria, Tunisia, Ukraine, United States of America and WHO (World Health Organisation).

I. PREFACE

The European Pharmacopoeia was inaugurated in 1964 through the Convention on the Elaboration of a European Pharmacopoeia under the auspices of the Council of Europe. The 6th Edition of the European Pharmacopoeia is published at a time coinciding with the 43rd Anniversary of the Pharmacopoeia Convention and marks the occupation of the new purpose-designed headquarters building of the EDQM, the European Directorate for the Quality of Medicines & HealthCare, in Strasbourg. The work of the Pharmacopoeia has gone through a remarkable development, from the early publications of the 1st Edition to the strong position of the 4th, 5th and 6th Editions that follow the current three-year cycle of publication with intermittent thrice-yearly supplements.

The monographs of the Pharmacopoeia, both specific and general, together with other texts made mandatory by virtue of reference in monographs, are applicable throughout the 37 Member States including the European Union itself, which is also a signatory to the European Pharmacopoeia Convention. This means that the European Pharmacopoeia holds a special place in the regulatory processes within the European Union, its text being made mandatory or given 'mandatory' applicability by virtue of reference in European Council Directives. In addition to the 37 signatories to the European Pharmacopoeia Convention, there are also a large number (20) of observer countries. Consequently, the quality standards developed through the Pharmacopoeia have an impact on the quality of medicinal products and substances used across a large part of the globe.

Since the 5th Edition (2004), the European Pharmacopoeia in paper copy has had to be lodged in a two-volume set for simple practical reasons. The 6th Edition will become effective on 1 January 2008 and be augmented with eight supplements, three per annum, implementing on a rapid basis the decisions of interim meetings of the European Pharmacopoeia Commission. This flexible publication schedule has allowed a shortening of the time span between adoption of monographs by the Commission and their publication and official status. This reduced time span becomes possible only due to the very flexible attitude of those countries that make national translations of those European Pharmacopoeia monographs, which are published bilingually by the European Pharmacopoeia only in its working languages of English and French. The European Pharmacopoeia is of course also available in CD-ROM format as well as electronically online. Electronic versions are becoming increasingly popular and therefore tend to dictate the way the Pharmacopoeia is produced to meet modern expectations. The three-year publication schedule that began with the 4th Edition continues with this current edition and will be the pattern set for the foreseeable future. By this process the stability and flexibility of the publication schedule is maximised and the publication remains user-friendly.

Elaboration and approval of monographs and other texts proceeds through an efficient and transparent, smooth-running process, based on scientific co-operation between the members of the various Groups of Experts and Working Parties assigned by the European Pharmacopoeia Commission, the governing body of the Pharmacopoeia. These experts give of their time, expertise and experience to produce the highest-level quality standards available to the public, standards that are continually revised in line with scientific developments. This co-operation between the experts from industry, academia, regulatory authorities and official government laboratory scientists represents the pinnacle of scientific co-operation to produce a high standard of technical monographs and chapters. The current edition will contain in excess of two-thousand monographs, each of which has gone through the painstaking elaboration and/or revision process ultimately directed by the Commission and subject to extensive and transparent public consultation through the medium provided by *Pharmeuropa*, the quarterly publication of the EDQM. Furthermore, the technical requirements adopted by the Pharmacopoeia Commission are based upon a unanimous decision-making process – each Member State of the Pharmacopoeia Commission has the right to veto, should they choose to exercise it.

The eight founder countries of the Convention realised in 1964 that manufacturing and quality control standards for medicinal products on the European market had to be harmonised for reasons of public health and to facilitate the free movement of medicines. Since 1964, the pharmaceutical world has changed radically and the market for medicinal products has become global. Accordingly, international harmonisation among the three major pharmacopoeias of the world, the European Pharmacopoeia, the Japanese Pharmacopoeia and the United States Pharmacopoeia, has been in progress since 1990 when the Pharmacopoeial Discussion Group was set up to co-ordinate the harmonisation work. In the first years, the work was focused on the harmonisation of monographs on widely used excipients. In the absence of harmonised general methods this was a difficult task, which has now been speeded up by 'harmonisation by attribute', meaning that there may be tests that cannot be fully harmonised before the general method concerned is harmonised. At the stage where the monographs are harmonised, detailed information will be provided in the monograph and in the general chapter *5.8. Pharmacopoeial harmonisation*, which is devoted to information on international harmonisation. In recent years, harmonisation of a wide range of general methods has been in progress, partly because of the impact from the International Conference on Harmonisation (ICH) and in particular the work of its guideline on specification-setting (Q6A). Implementation in the Pharmacopoeia of harmonised general methods, for example for a dosage form specification, needs careful consideration however, because the specification must be met by products already on the market as well as new products submitted to the regulatory process.

The European Pharmacopoeia Commission supports strongly the international harmonisation initiative. It is not the harmonisation work itself that gives rise to the greatest problems, rather the implementation, which has to be decided by mutual agreement with the European regulatory authorities. In response the links between the European Pharmacopoeia Commission and European regulators have been steadily strengthened during the years, as have the links with the pharmaceutical manufacturers and their associations. The European Pharmacopoeia has a particular statutory role in the EU Medicines legislative system, which helps to strengthen the harmonisation initiative, notwithstanding that the Pharmacopoeia has an audience wider than the EU Member States.

The growing number of monographs on pharmaceutical substances and the need to keep them updated means an increased workload for the Groups of Experts. There

continues to be a need for more experts with access to experimental facilities as permanent members of the Groups of Experts or as members on an *ad hoc* basis. In addition to the reorganisation of the system of Groups of Experts and Working Parties, the working procedures for the elaboration of monographs have also been expanded to four different procedures.

- *Procedure 1*, the traditional elaboration by Groups of Experts.
- *Procedure 2*, adaptation of national monographs.
- *Procedure 3*, applying to substances produced by only one manufacturer, usually close to patent expiry. In this procedure, the manufacturer and national pharmacopoeial authority in the country where the substance is produced carry out the preliminary drafting stages and check the requirements experimentally. The draft is then reviewed by a Working Party and processed in the usual way by public enquiry.
- *Procedure 4*, a modified version of Procedure 3, introduced by the Commission in 2002 to further streamline the process. Procedure 4 involves collaboration between the manufacturer of the substance and the EDQM to prepare a draft monograph with experimental checking by the EDQM laboratory before publication for public enquiry.

  A Working Party has been set up to supervise this process and prepare the draft monographs in the usual way, but with the ability to have direct collaboration between the manufacturer and the EDQM laboratory in refining the experimental method. This results in rapid preparation of monographs on substances still under patent. The collaboration with innovators and manufacturers of such active substances established in recent years has proved to be very successful.

For the 6th Edition, the normal procedures now used for production of monographs are in effect Procedures 1 and 4, since the processes of adaptation of national monographs and the Procedure 3 route have been largely exhausted and the work done through these two procedures is largely complete.

The codified European Directives 2001/83/EC and 2001/82/EC as amended, on medicines for human and veterinary use, maintain the mandatory character of the European Pharmacopoeia monographs in the preparation of dossiers for marketing authorisation of medicines. It is therefore essential that the monographs of the European Pharmacopoeia be updated to keep pace with product development, with scientific progress, and with regulatory requirements. In the field of active pharmaceutical substances, the European Pharmacopoeia Commission has decided that the principles and terminology of the revised ICH Q3A impurity testing guideline *Impurities in new drug substances* should as far as possible be implemented in the monographs on active substances, both new and already published. A change in terminology has been introduced in the Impurities section of monographs published since Supplement 4.6, where the term 'specified impurities' is used for impurities that have defined individual acceptance criteria. A revision of the general monograph *Substances for pharmaceutical use (2034)* was also presented in the 5th Edition to implement the threshold values of the revised ICH guideline Q3A (R) for reporting, identification and qualification of organic impurities in active substances. For the 5th Edition a new chapter, *5.10. Control of impurities in substances for pharmaceutical use*, was developed with great assistance from the chairs of the chemical Groups of Experts and other experts from the Commission, and by consultations of the Groups of Experts.

The next step was the revision of monographs to ensure that they contain related substances tests and lists of specified and other detectable impurities. Monographs containing a related substances test based on TLC are being revised and the work will thus proceed during the coming years. Hopefully, these revisions can be completed during the publication of the 6th Edition. In the meantime, users of the Pharmacopoeia must consult the new general chapter *5.10* on impurity control for the interpretation of monographs published in the past and therefore adapted to a style that has now been changed as described above. Users can in addition find information on representative chromatograms, reagents and columns used in drafting the monographs on the EDQM Knowledge database.

The aim of the revisions is to ensure that the related substances tests and impurity lists reflect the purity of pharmaceutical substances authorised for the European market. The goal cannot be met without close collaboration with the registration authorities and consultations regarding the specifications for impurities. A procedure for co-operation with the CHMP/CVMP Quality Working Party has been established, which has contributed to ensuring the validity of monographs. The Certification of Suitability of Monographs of the European Pharmacopoeia can also be a valuable source of information on the purity of pharmaceutical substances. The procedure is, however, confidential and will be kept so. In cases where a new impurity is present and calls for revision of the monograph, this can be done only when the manufacturer agrees to provide the relevant Group of Experts with the information required for updating.

Since the 5th Edition of the European Pharmacopoeia, a number of excipient monographs have contained a non-mandatory section on functionality-related characteristics (FRCs). The aim of this section is to provide users with a list of physical and physicochemical characteristics that are critical to the typical uses of the concerned excipient, and to provide the general methods required to assess these characteristics. The section does not necessarily give acceptance criteria for the concerned properties; this is usually left as an option for labelling by the manufacturers and, where specified, the values are indicative only. This development is in line with the policy of the European Pharmacopoeia Commission to make monographs and other texts appropriate to the needs of regulatory authorities and manufacturers of starting materials and medicinal products. The intention is to provide manufacturers of excipient materials and manufacturers of medicinal products a 'common language' to facilitate the establishment of product-specific specifications, and to provide regulators with data generated by methods that have been independently assessed.

Over the last three years the European Pharmacopoeia Commission has developed this work by drafting sections on FRCs in monographs on excipients available in more than one physical grade. Introduction of the concept of FRCs presupposes that the relevant general methods are available in the Pharmacopoeia. The European Pharmacopoeia Commission has therefore established a Working Party on FRCs to investigate the need for general methods for controlling these properties and to collaborate with the Working Party on powder-characterisation methods. The provision of the necessary general methods, for example in the field of powder characterisation, has also been included in international harmonisation among the pharmacopoeias.

Furthermore, a general chapter on FRCs has been developed and published in *Pharmeuropa* for incorporation into the 6th Edition.

A general chapter on viral safety has been published by the European Pharmacopoeia, intending to reinforce the need for all substances of human or animal origin to demonstrate freedom from the possibility of contamination by viruses by careful control of starting materials and manufacturing process conditions. In completing the work on the preparation of this general chapter, the EDQM greatly appreciates the input of the European Medicines Agency (EMEA) in its very substantial contribution. This general chapter (*5.1.7*) was published in the final supplement to the 5th Edition and emphasises the importance of carrying out a risk assessment on viral safety of materials of human or animal origin. In turn, a number of general monographs covering allergens, extracts, immunosera, monoclonal antibodies, products of recombinant DNA technology, vaccines and substances for pharmaceutical use generally are cross-referring to this chapter on viral safety to re-emphasise the importance of this attribute.

During 2005, the EDQM held a very useful symposium on traditional Chinese (and other ethnic) medicines, which was set up to consider the possibility of preparing quality standards to deal with such substances and to develop a new role for the European Pharmacopoeia in this area. Based on some very useful suggestions from the seminar, it was agreed that the two herbal medicinal products Groups of Experts (Groups 13A and 13B) would be asked to prepare draft monographs based on the information that was already available in some Member States where national monographs on such substances were available or under preparation, and also taking into consideration the very useful collaboration that had been established with the Chinese Pharmacopoeia authorities. The first of these TCM monographs are published in the 6th Edition, and it is hoped that many more will follow to supplement the growing importance of regulation of such substances and their products on the European market.

Work on homoeopathic medicinal products also progressed well during the last three years, and in particular an agreement to incorporate into the Pharmacopoeia specific chapters dealing with homoeopathic manufacturing methods based on information available in existing Homoeopathic Pharmacopoeias within Europe. As a result of this progress, a new Working Party on homoeopathic manufacturing methods has been established and will work very closely with the existing Homoeopathic Products Working Party in a renewed effort at developing meaningful standards for such products. Once again, the Pharmacopoeia has worked closely with the Regulatory Authorities within the EU in attempting to achieve these goals.

The achievements of the European Pharmacopoeia Commission during the past three years would not have been possible without the participation of the great number of experts from industry, academia and national authorities, who have given of their time and expertise to participate in the work of Groups of Experts and Working Parties. The Commission is indebted to all these experts whose work is given on a voluntary basis. The Commission is equally indebted to the Chairs of the Groups and Working Parties who have the responsibility of guiding the work through and bringing it to term according to tight time limits. The Chairs are thanked for their contributions within the Groups and also for their advice and counsel to the Commission itself.

The work of the European Pharmacopoeia Commission is also totally dependent on an effective Secretariat. The role of the Secretariat is to obtain and process all the information and reports needed for the Groups of Experts, Working Parties and for the Commission; to undertake laboratory work to support the experts; and to ensure the availability of all the reference standards needed to allow the requirements in the monographs to be tested. The prompt publication of the Pharmacopoeia main volumes and Supplements and the online electronic version is possible only because of professionalism, dedication and hard work by the staff of the EDQM Secretariat.

Along with the growing size of the European Pharmacopoeia and its adjustment to the regulatory process, the use of the Pharmacopoeia and its interpretation has become rather complex. The journal of the European Pharmacopoeia, *Pharmeuropa*, is a valuable source of information. General chapters for information will continue to appear in the Pharmacopoeia during the publication of the 6th Edition as a result of the international harmonisation efforts and because the European Pharmacopoeia Commission has agreed on the elaboration of other chapters for information. During the past few years, the staff at the EDQM have offered training courses to users of the Pharmacopoeia. The Commission is grateful to the EDQM for having taken this initiative, which also strengthens the role of the Pharmacopoeia and the links to its users. The links to users of the Pharmacopoeia are also strengthened by the frequent workshops and conferences organised by the EDQM. This activity is highly valued by the Commission as it gives the opportunity to Commission members to exchange viewpoints and to discuss new developments with experts from authorities, industry and academia. The EDQM website is another valuable source of information on the work programme and other activities of the Commission, its Groups and the EDQM, with both the Knowledge Database and the HelpDesk, which provides a question and answer service.

During the past three years I have had the honour and privilege to serve the European Pharmacopoeia Commission as its elected Chair. The task has been challenging and extremely rewarding because of the insight it has given me into the many elements of the work that go into the drafting of the quality standards that are provided by the texts of the Pharmacopoeia. The close relationship that binds regulatory processes in Europe with the standards provided by the Pharmacopoeia is essential in maintaining public health.

I wish to thank all members of the European Pharmacopoeia Commission for their support and the collaborative spirit they have displayed within and between the Sessions of the Commission. Together with the excellent work of the two vice-chairs of the Commission and the Director and the Secretary to the Pharmacopoeia we have collaborated very effectively as the Presidium to guide the work of the Commission. I sincerely thank the Presidium for their wisdom and support during my time as Chair. The staff of the EDQM have been extremely supportive and it is clear that this work could not have been accomplished without their patience, hard work and professionalism and I owe them all a debt for the collaboration and friendship they have shown to me, especially in my tenure in the Chair.

Finally, I wish to express my sincere thanks to the Director of the EDQM, Dr Agnes Artiges, and her deputy as Secretary to the European Pharmacopoeia Commission, Mr Peter Castle. I have long appreciated our collaboration but especially during the last three years and wish to express heartfelt thanks to both for their support to the Chair and for the tremendous work they are doing to develop the European Pharmacopoeia and its role in the European regulatory system.

Dr J. Michael Morris

Chair of the European Pharmacopoeia Commission

II. INTRODUCTION

The European Pharmacopoeia is prepared under the auspices of the Council of Europe in accordance with the terms of the Convention on the elaboration of a European Pharmacopoeia (European Treaty Series No. 50) as amended by the Protocol to the Convention (European Treaty Series No. 134), signed by the Governments of Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Montenegro, Netherlands, Norway, Poland, Portugal, Romania, Serbia, Slovak Republic, Slovenia, Spain, Sweden, Switzerland, 'the former Yugoslav Republic of Macedonia', Turkey, United Kingdom, and by the European Union.

The preparation of the Pharmacopoeia is the responsibility of the European Pharmacopoeia Commission ('the Commission'), appointed in accordance with Article 5 of the above-mentioned Convention. It is composed of delegations appointed by the Contracting Parties. Each delegation consists of not more than 3 members chosen for their competence in matters within the functions of the Commission.

Observers from non-Member States and international organisations are admitted to Sessions of the Commission in accordance with the Rules of Procedures. Observers are at present admitted from: Albania, Algeria, Australia, Belarus, Brazil, Canada, China, Georgia, Israel, Kazakhstan, Madagascar, Malaysia, Morocco, Russian Federation, Senegal, Syria, Tunisia, Ukraine, United States of America and the World Health Organisation.

The Convention is open for signature by European countries and observer status can serve to familiarise European countries intending to become signatories with the working methods of the Commission. The Commission recognises that relations with countries outside Europe are essential in view of the globalisation of the supply chain for pharmaceuticals. Observer status for non-European countries helps to foster these relations by facilitating regulatory partnerships and the exchange of information and working documents.

The functions of the Commission established by Article 6 of the Convention as amended by the Protocol are:

Article 6

"Subject to the provision of Article 4 of the present Convention, the functions of the Commission shall be:

(a) to determine the general principles applicable to the elaboration of the European Pharmacopoeia;

(b) to decide upon methods of analysis for that purpose;

(c) to arrange for the preparation of and to adopt monographs to be included in the European Pharmacopoeia and;

(d) to recommend the fixing of the time limits within which its decisions of a technical character relating to the European Pharmacopoeia shall be implemented within the territories of the Contracting Parties."

In accordance with the terms of the Convention, the Contracting Parties undertake to take the necessary measures to ensure that the monographs of the European Pharmacopoeia shall become the official standards applicable within their respective territories.

PURPOSE OF THE EUROPEAN PHARMACOPOEIA

The purpose of the European Pharmacopoeia is to promote public health by the provision of recognised common standards for use by healthcare professionals and others concerned with the quality of medicines. Such standards are to be appropriate as a basis for the safe use of medicines by patients and consumers. Their existence:

- facilitates the free movement of medicinal products in Europe;
- ensures the quality of medicinal products and their components imported into or exported from Europe.

European Pharmacopoeia monographs and other texts are designed to be appropriate to the needs of:

- regulatory authorities;
- those engaged in the control of quality of medicinal products and their consitutents;
- manufacturers of starting materials and medicinal products.

The European Pharmacopoeia is widely used internationally. It is the intention of the Commission to work closely with all users of the Pharmacopoeia in order to satisfy better their needs and facilitate their co-operation. To this end improved procedures are being developed for obtaining advice on priorities for elaborating new monographs and enhancing the quality of the European Pharmacopoeia.

EUROPEAN PHARMACOPOEIA HEADQUARTERS

The headquarters of the European Pharmacopoeia are situated in Strasbourg with a Scientific Secretariat, a Publications and Multimedia Department and a Laboratory, the latter being charged, among other duties, with the establishment and monitoring of the reference standards needed for the monographs of the Pharmacopoeia. These departments are parts of the European Directorate for the Quality of Medicines & HealthCare (EDQM) of the Council of Europe.

GENERAL PRINCIPLES

General rules for interpretation of the texts of the European Pharmacopoeia are given in the General Notices. The following information should also be noted.

The general principles applied in the elaboration of monographs of the European Pharmacopoeia are laid down in technical guides available on the EDQM website. The principles applied are revised from time to time without complete retrospective application so that monographs already published may not always follow the latest recommendations, but wherever an issue with an impact on public health is identified, monographs are revised.

It is recognised that general chapters are used elsewhere than in the monographs of the Pharmacopoeia; in these circumstances users are recommended to consult the relevant Technical Guide, which gives extensive information on the application of many of the methods.

General and individual monographs. The standards of the European Pharmacopoeia are represented by general and individual monographs. The use of *general monographs* has developed in recent years to provide standards that best fulfil the aims stated above and meet the needs of users. From the 4th Edition, the scope of general monographs was extended, except where otherwise stated, to cover products where there is no individual monograph. It is now usually necessary to apply one or more general monographs along with any

individual monograph. Where a substance is subject to the provisions of both a general monograph and an individual monograph, the two are complementary. An individual monograph may, exceptionally, include an exemption from one or more provisions of the general monograph.

Since it is not practically possible to include in each individual monograph a cross-reference to applicable or potentially applicable general monographs, cross-referencing has been discontinued except where it is necessary to avoid ambiguity. A list of general monographs is included in each new edition and supplement to aid users in identifying those that are needed for use with an individual monograph.

Use of animals. In accordance with the *European Convention on the protection of animals used for experimental and other scientific purposes (1986)*, the Commission is committed to the reduction of animal usage wherever possible in pharmacopoeial testing, and encourages those associated with its work to seek alternative procedures. An animal test is included in a monograph only if it has clearly been demonstrated that it is necessary to achieve satisfactory control for pharmacopoeial purposes.

Hydrates. With the publication of the 4th Edition, the policy on monograph titles for hydrated forms was changed. For all monographs published for the first time in the 4th Edition or subsequent editions, the degree of hydration, where applicable, is indicated in the monograph title. In previous editions, the policy was to indicate the degree of hydration only where several forms exist. If a monograph on both an anhydrous and a hydrated form of a given substance are published, then 'anhydrous' will be included in the title of the relevant form. In order to avoid placing an unnecessary burden on manufacturers for relabelling, this policy will not be applied retrospectively to monographs published already, unless there is reason to believe that this is justified as a public health measure, notably for safety reasons where the substance contains a large proportion of water.

Chiral substances. Monographs on chiral substances that describe a particular enantiomer have a test to confirm enantiomeric purity, usually by measurement of optical rotation. Monographs that describe racemates are, in this respect, heterogeneous because of changes of policy during the 3rd Edition. Older monographs do not always have a test to show racemic character. During the course of the 3rd Edition, a test for racemic character was included in all new and revised monographs on racemates, using measurement of optical rotation. When it was shown that in many cases a test for optical rotation, even with narrow limits around zero rotation, was not necessarily sufficiently discriminating because of the low specific optical rotation of the enantiomers, the Commission modified the policy applied. A test for racemic character using optical rotation is now included only if there is information on the specific optical rotation of the enantiomers that indicates that such a test would be discriminating in terms of enantiomeric purity. If other techniques, such as circular dichroism, can serve the intended purpose, they will be prescribed instead of optical rotation.

Polymorphism. Where a substance shows polymorphism, this is usually stated under Characters. In general, no particular crystalline form is required in monographs; exceptionally, in a few monographs, the crystalline form required is specified, for example, via an infrared absorption spectrophotometric identification test where the spectrum is required to be recorded using the substance in the solid state without recrystallisation, the chemical reference substance provided being of the required crystalline form. However, for substances other than these exceptional cases, depending on the use of a given substance in a dosage form, it may be necessary for a manufacturer to ensure that a particular crystalline form is used. The information given under Characters is intended to alert users to the need to evaluate this aspect *during the development of a dosage form*. The general monograph *Substances for pharmaceutical use (2034)* and general chapter *5.9. Polymorphism* should also be consulted.

Specificity of assays. For the elaboration of monographs on chemical active substances, the approach generally preferred by the Commission is to provide control of impurities (process-related impurities and degradation products) via a well-designed Tests section, with stability-indicating methods, rather than by the inclusion of an assay that is specific for the active moiety. It is therefore the full set of requirements of a monograph that is designed to ensure that the product is of suitable quality throughout its period of use.

Impurities. Following a review of policy on control of impurities, a new general chapter *5.10. Control of impurities in substances for pharmaceutical use* was included in the 5th Edition. Together with the general monograph *Substances for pharmaceutical use (2034)*, it describes the policy of controlling impurities in individual monographs and provides explanations on how the limits in the related substances test should be understood.

The current general policy of the Commission is to include quantitative tests for impurities in monographs. Older monographs elaborated before the establishment of this policy are the subject of a special revision programme to introduce quantitative methods. Where a monograph does not conform to the general policy, compliance with the general monograph *Substances for pharmaceutical use (2034)* will usually imply that the individual monograph requirements need to be supplemented accordingly.

Except where required for the application of the monograph, in which case the name is followed by 'CRS', impurities are not provided as reference standards nor can they be provided for experimental purposes.

Chromatographic columns. As an aid to users, information is made available via the website (see also Knowledge database, below) on chromatographic columns that have been found to be satisfactory during development of monographs and general methods. Information is also given on other equipment and reagents where this is considered useful. This information is given without warranty and does not imply that other columns, equipment or reagents than those specified are not suitable.

Residual solvents. The requirements for residual solvents are given in the general monograph *Substances for pharmaceutical use (2034)* and general chapter *5.4. Residual solvents*. Thus all active substances and excipients are subject to relevant control of residual solvents, even where no test is specified in the individual monograph. The requirements have been aligned with the ICH guideline on this topic.

Medical devices. All editions of the Pharmacopoeia have contained monographs on articles that are regarded as medical devices. For Member States of the European Union, a unified framework for standardisation of medical devices is now provided by a Directive (93/42/EEC). Following an agreement between the various parties involved, the Commission has decided that the monographs on medical devices will be deleted once standards have been developed as foreseen by the Directive. Specifications included in the section on containers will be adapted to take account of future standards developed within the framework of the Directive. The monographs on surgical sutures remain in the

Pharmacopoeia but they have been modified to conform to the requirements of the Directive and are now to be seen as standards of the type foreseen there. This adaptation of the monographs has involved the deletion of some monographs on specific types of sutures in favour of a more general approach.

Homoeopathic preparations. A monograph on methods of preparation of homoeopathic stocks and potentisation, general monographs on homoeopathic preparations, mother tinctures for homoeopathic preparations and herbal drugs for homoeopathic preparations, and individual monographs on raw materials and stocks for homoeopathic preparations are included in a separate section of the European Pharmacopoeia. It is understood that when the same substance is used in both homoeopathic and other preparations then the monograph in the main body of the European Pharmacopoeia applies.

Functionality-related characteristics. Following a policy decision of the Commission, increased attention is being given to functionality-related characteristics of excipients. A new information section has been created in the monographs. The contents of this section do not constitute mandatory requirements but the characteristics may be relevant for a particular use of an excipient. The characteristics may be presented in different ways:

- citing the name only;
- citing the name and a suitable test method, preferably one included in the European Pharmacopoeia;
- citing the name, a suitable test method and typical values or tolerances on the stated value; these values or tolerances are used to define a suitable grade of an excipient for a particular use.

In all cases, the method and acceptance criteria are not mandatory requirements but are given for guidance. The decision to control a functionality-related characteristic of an excipient remains with the pharmaceutical manufacturer and is taken with knowledge of the formulation of the product in which it is to be used; the method of determination, acceptance criteria and tolerances are determined on a contractual basis by the user and the supplier of the excipient.

The Commission's aim is to highlight the need for attention to functionality-related characteristics and to foster harmonisation of methods for their evaluation.

Editorial revision of monographs. During the course of the 3rd Edition, a new, improved editorial style was adopted, particularly for monographs on organic chemicals. New and extensively revised monographs were generally published in the new style for the 4th and 5th Editions. During the 5th Edition, a new, improved editorial style was adopted for monographs on veterinary vaccines. For the 6th Edition, a large number of monographs published in the old style for the 5th Edition have been converted to the new style so that there is greater uniformity in editorial presentation. Conversion to the new style does not affect the technical content of the monographs. Since the editorial revision does not affect the technical content, the changes are not tracked by the use of lines in the margin.

Patents. The description in the European Pharmacopoeia of articles subject to protection by patent does not confer or imply any right to the use of such patents by any person or persons other than the proprietors of the patents concerned.

Chemical Abstracts Service (CAS) registry number. In the 6th Edition, CAS registry numbers have been included for information in monographs, where applicable, to provide convenient access to useful information for users. Previously these numbers were given only for reagents, where they are of use in locating suppliers. CAS Registry Number® is a Registered Trademark of the American Chemical Society.

Protected species. Monographs, notably those on herbal drugs, may cover material obtained from protected species. Inclusion of these monographs is without prejudice to the provisions for protection of these species by national and international law.

MONOGRAPHS ON PHARMACEUTICAL PREPARATIONS

According to the current policy of the Commission, monographs on pharmaceutical preparations are not elaborated, with the exception of those on immunosera for human use, immunosera for veterinary use, some biological preparations such as insulin preparations, radiopharmaceutical preparations, vaccines for human use and vaccines for veterinary use. This policy has been established since:

- the specifications for a given preparation are approved by the competent authority in light of data from pharmaceutical development work and stability studies; a unique specification for the dosage form of a given active substance would therefore be inappropriate in most instances;
- specifications for a pharmaceutical preparation depend on factors related to the particular formulation and a mandatory quality standard could hamper innovation and improvement by setting acceptance criteria that are contingent rather than essential.

Harmonisation and standardisation for pharmaceutical preparations have so far been dealt with via the drafting of general dosage form monographs setting out elements common to all preparations within the scope of the monograph, and via the development of standard test methods used for testing of finished products. The inclusion of these general monographs and methods in the European Pharmacopoeia gives a common basis for competent authorities and manufacturers in the preparation and evaluation of applications for marketing authorisation.

Reference standards established for the assay of active substances and excipients may be suitable for use as assay standards for preparations when the conditions stated in general chapter *5.12. Reference standards* are fulfilled.

WORK PROGRAMME

The work programme (elaboration of new monographs or general chapters or revision of existing texts) is decided by the Commission at one of the three annual sessions. In general, whenever two Member States express a wish to elaborate a monograph, the Commission adds the item to the work programme. Changes to the work programme are published on the EDQM website and in *Pharmeuropa*. Information is also provided to industry associations registered with the Secretariat and to manufacturers' liaison contacts. Interested parties are invited to contact the Secretariat for any items where they wish to be involved in the work.

CERTIFICATION PROCEDURE

A procedure for the certification of suitability of monographs of the Pharmacopoeia with respect to control of the quality of a product from a given source has been established [see Public Health Committee (Partial Agreement) Resolution AP-CSP (99) 4 or any subsequent revision, available from the EDQM and on its website] as an aid to the use of monographs in applications for marketing authorisation. The certification procedure also applies to herbal drugs, herbal drug preparations and transmissible spongiform

encephalopathy (TSE) risk. Certificates of suitability are issued by the EDQM only for substances produced under a suitable quality system. Certificates are granted with respect to published monographs. Details of the operation of this scheme are available from the Secretariat and on the EDQM website. A daily updated list of certificates granted is available online on the EDQM website, including voided or suspended certificates.

PUBLICATIONS

The official version of the European Pharmacopoeia is available in English and in French, in the form of a book with 3 supplements per year, and in electronic form (online and CD-ROM). An electronic version in Spanish has been available since July 2006 for the convenience of Spanish-speaking users.

Pharmeuropa, the European Pharmacopoeia Forum, is published 4 times per year as an aid for the elaboration of monographs and as a vehicle for information on pharmacopoeial and related matters. *Pharmeuropa Bio*, a publication indexed by bibliographic services, includes papers mainly related to the establishment of biological reference preparations and validation of biological methods within the Biological Standardisation Programme of the EDQM. *Pharmeuropa Scientific Notes*, a publication indexed by bibliographic services, presents scientific papers on all aspects of pharmaceutical analysis and other subjects relevant to the Pharmacopoeia.

Website. Information on activities and many other aspects of the European Pharmacopoeia is to be found on the EDQM website.

Knowledge database. The EDQM website provides access to a database containing information of various sorts related to monographs and intended to facilitate their proper use. Information is provided on:

- chromatography columns used in monograph development;
- suppliers of reagents and equipment that may be difficult to find for some users;
- the status of monographs (in development, adopted, published, under revision);
- revisions of the monographs on a historical basis, beginning from the 5th Edition;
- other useful information.

HelpDesk. Many technical and other enquiries are addressed to the EDQM by users. They should be submitted via the HelpDesk on the EDQM website. The EDQM will deal with enquiries that are related to the use of monographs of the European Pharmacopoeia. The HelpDesk has a section of Frequently Asked Questions that should be consulted by users before submission of an enquiry.

Implementation. The date on which monographs are to be implemented is fixed by a Resolution of the Public Health Committee (Partial Agreement) of the Council of Europe, following a recommendation by the Commission. This date is usually 1 year after adoption and about 6 months after publication. Where a monograph is to be implemented at a date earlier than the next publication date of the European Pharmacopoeia or a supplement, a Resolution of the Public Health Committee gives the full text to be implemented. The text is also published in *Pharmeuropa* for information and posted on the EDQM website as part of the Resolution.

Revision programme. Monographs and other texts of the European Pharmacopoeia are revised as necessary following a decision of the Commission. Revision proposals are published in *Pharmeuropa*. Proposals to revise monographs may be submitted by a delegation, by the Chair of the Commission or by the chair of a group of experts. Requests for revision from other parties should be submitted via the national pharmacopoeia authority of a Member State or, where this is not possible, to the EDQM, preferably via the HelpDesk. Proposals to revise monographs must be accompanied by sufficient data to justify the need for revision.

COMBISTATS

Certain tests in monographs, particularly biological assays, require statistical analysis of the results. The EDQM has developed a computer programme, CombiStats, that can be used for statistical analysis of results of biological dilution assays. Information on the programme, with conditions of access and use, is available on the EDQM website.

INTERNATIONAL HARMONISATION

The European Pharmacopoeia is engaged in a process of harmonisation with the Japanese Pharmacopoeia and the United States Pharmacopeia, within an informal structure referred to as the Pharmacopoeial Discussion Group (PDG). The activities are developed in co-ordination with those of the International Conference on Harmonisation (ICH). Information on the status of harmonised texts is given in general chapter *5.8. Pharmacopoeial harmonisation* and on the PDG page of the EDQM website. Harmonised general chapters have a preliminary statement indicating interchangeability with the other two pharmacopoeias.

III. EUROPEAN PHARMACOPOEIA COMMISSION

COMPOSITION OF THE COMMISSION, LIST OF EXPERTS AND OF THE SECRETARIAT AS OF 30 NOVEMBER 2006

CHAIR AND VICE-CHAIRS OF THE COMMISSION

Chair	Michael	MORRIS
Vice-chairs	Hendrick Jan	DE JONG

IV. CONTENTS OF THE 6th EDITION

The 6th Edition consists of all texts published in the 5th Edition, which may subsequently have been revised or corrected, and new texts.

For the information of the reader, lists are given below of monographs and general chapters that are new, or that have been revised, corrected or deleted, and texts whose title has been changed for the 6th Edition.

The version date (01/2008 for volume 6.0) and the reference number (4 digits for monographs and 5 digits for general chapters) are specified above the title of each text (monographs and general chapters). The version date makes it possible to identify the successive versions of revised texts in different volumes of the 6th Edition. Corrections that are indicated by the note 'corrected 6.0' under the version date are to be taken into account from the publication date of the volume.

For the 6th Edition, the following systematic modifications have been made to the texts of the European Pharmacopoeia.

- In the test for loss on drying (*2.2.32*) in the monographs, the temperature range of 100-105 °C has been replaced by 105 °C alone (as the general method states that drying is carried out at the prescribed temperature ± 2 °C), to follow the approach adopted by the Pharmacopoeial Discussion Group for pharmacopoeial harmonisation.
- In the test for loss on ignition in the monographs, a temperature range has been introduced.
- In tests using atomic absorption spectrometry and atomic emission spectrometry, the precision of the limits has been increased.
- In the Characters section, 'white' has been replaced by 'white or almost white'.
- In the Labelling section, it will no longer be mentioned that, where appropriate, the label includes statements that the substance is free from bacterial endotoxins, free from pyrogens and sterile since this information is already included in the general monograph *Substances for pharmaceutical use (2034)*. This also applies to the indication of the name and the concentration of any added substance (excipient, antioxidant, etc.).
- In the transparency list, letters designating an impurity followed by 'deleted' will no longer be included in the monographs; it is now permissible for the list of impurities to be discontinuous.
- Where appropriate, the *Chemical Abstracts Service* (CAS) registration numbers are given for information in the monographs.
- The retention factor R_f has been replaced by the retardation factor R_F.
- In monographs on antibiotics, the upper limit of content has been increased to 102 per cent when an assay is carried out using liquid chromatography.
- In monographs on antibiotics, where appropriate, the definition mentions that the substance is a 'semi-synthetic product derived from a fermentation product' or a 'fermentation product'.
- In monographs on herbal drugs, the usual limit of 2 per cent *m/m* for foreign matter has been moved from general method *2.8.2. Foreign matter* to the general monograph *Herbal drugs (1433)*; this information has therefore been deleted from the specific monographs for drugs covered by this general monograph.
- In monographs on herbal drugs, the reference to identifications A and B (macroscopic and microscopic descriptions) has been deleted from the Characters section.
- In accordance with the general monograph *Substances for pharmaceutical use (2034)*, the content of residual solvent is taken into account for calculation of the assay content of the substance, the specific optical rotation and the specific absorbance. This information is therefore no longer indicated in the specific monographs concerned.
- The general monographs *Herbal drugs (1433)* and *Extracts (0765)* specify storage protected from light; this information has therefore been deleted from the specific monographs on substances and preparations covered by these general monographs.
- A reference to general chapter *2.1.2. Comparative table of porosity of sintered-glass filters* has been added whenever reference is made to 'sintered-glass filters'.
- A reference to general chapter *2.9.12. Sieve test* has been added whenever particle or granule size is indicated by a sieve number.
- A reference to general chapter *5.9. Polymorphism* has been added to monographs in which polymorphism is mentioned.
- Where the heading 'Other detectable impurities' appears in the Impurities section of a monograph, it is now followed by: '(the following substances would, if present at a sufficient level, be detected by one or other of the tests in the monograph. They are limited by the general acceptance criterion for other/unspecified impurities and/or by the general monograph *Substances for pharmaceutical use (2034)*. It is therefore not necessary to identify these impurities for demonstration of compliance. See also *5.10. Control of impurities in substances for pharmaceutical use*)'.
- Many monographs have been converted to the new editorial style, which does not entail any changes to their technical content. The list of monographs on chemical substances and herbal drugs concerned is available on the EDQM website.

A vertical line in the margin indicates where part of a text has been revised or corrected. A horizontal line in the margin indicates where part of a text has been deleted. It is to be emphasised that these indications, which are not necessarily exhaustive, are given for information and do not form an official part of the texts. Editorial changes are not indicated. Individual copies of texts will not be supplied.

NEW TEXTS INCLUDED IN THE 6th EDITION

GENERAL CHAPTERS

2.2.57. Inductively coupled plasma-atomic emission spectrometry

2.2.58. Inductively coupled plasma-mass spectrometry

2.7.28. Colony-forming cell assay for human haematopoietic progenitor cells

2.7.29. Nucleated cell count and viability

2.8.20. Herbal drugs: sampling and sample preparation

2.9.41. Friability of granules and spheroids

MONOGRAPHS

*The monographs below appear for the first time in the European Pharmacopoeia. They will be implemented on **1 January 2008** at the latest.*

Vaccines for human use

Cholera vaccine (inactivated, oral) (2327)

Vaccines for veterinary use

Rabbit haemorrhagic disease vaccine (inactivated) (2325)

Radiopharmaceutical preparations

Fluorodopa (^{18}F) (prepared by electrophilic substitution) injection (1918)

Monographs

Bistort rhizome (2384)

Dacarbazine (1691)

Devil's claw dry extract (1871)

Dextranomer (2238)

Dorzolamide hydrochloride (2359)

Felbinac (2304)

Fexofenadine hydrochloride (2280)

Flavoxate hydrochloride (1692)

Fluorescein (2348)

Glycerol monocaprylate (2213)

Glycerol monocaprylocaprate (2392)

Indinavir sulphate (2214)

Lansoprazole (2219)

Macrogol 40 sorbitol heptaoleate (2396)

Magnesium citrate, anhydrous (2339)

Methylergometrine maleate (1788)

Microcrystalline cellulose and carmellose sodium (2050)

Moxidectin for veterinary use (1656)

Norgestimate (1732)

Notoginseng root (2383)

Ritonavir (2136)

Ropivacaine hydrochloride monohydrate (2335)

Safflower flower (2386)

Vinpocetine (2139)

REVISED TEXTS IN THE 6th EDITION

GENERAL CHAPTERS

1. General notices

2.2.17. Drop point

2.2.22. Atomic emission spectrometry

2.2.23. Atomic absorption spectrometry

2.6.9. Abnormal toxicity

4. Reagents

5.1.4. Microbiological quality of pharmaceutical preparations

5.3. Statistical analysis of results of biological assays and tests

MONOGRAPHS

*The monographs below have been technically revised since their last publication. They will be implemented on **1 January 2008**.*

General monographs

Monoclonal antibodies for human use (2031)

Substances for pharmaceutical use (2034)

Dosage forms

Eye preparations (1163)

Rectal preparations (1145)

Vaginal preparations (1164)

Vaccines for human use

Influenza vaccine (surface antigen, inactivated, virosome) (2053)

Vaccines for veterinary use

Avian infectious bursal disease vaccine (inactivated) (0960)

Monographs

Adenosine (1486)

Allopurinol (0576)

Alteplase for injection (1170)

Amitriptyline hydrochloride (0464)

Ascorbyl palmitate (0807)

Benzbromarone (1393)

Boldo leaf (1396)

Calendula flower (1297)

Castor oil, hydrogenated (1497)

Cefamandole nafate (1402)

Cefepime dihydrochloride monohydrate (2126)

Cetyl palmitate (1906)

Chlortalidone (0546)

Cholecalciferol (0072)

Chondroitin sulphate sodium (2064)

Chymotrypsin (0476)

Clonidine hydrochloride (0477)

Clozapine (1191)

Copper sulphate, anhydrous (0893)

Copper sulphate pentahydrate (0894)
Dalteparin sodium (1195)
Danaparoid sodium (2090)
Diclofenac potassium (1508)
Diclofenac sodium (1002)
Diethylcarbamazine citrate (0271)
Dipyridamole (1199)
Dopamine hydrochloride (0664)
Enoxaparin sodium (1097)
Erythropoietin concentrated solution (1316)
Etodolac (1422)
Eucalyptus leaf (1320)
Fenofibrate (1322)
Fenoterol hydrobromide (0901)
Fluorouracil (0611)
Glucagon, human (1635)
Glycerol dibehenate (1427)
Gonadotrophin, chorionic (0498)
Heparin calcium (0332)
Heparin sodium (0333)
Heparins, low-molecular-mass (0828)
Human albumin solution (0255)
Human anti-D immunoglobulin (0557)
Human anti-D immunoglobulin for intravenous administration (1527)
Human plasma for fractionation (0853)
Human prothrombin complex (0554)
Hyaluronidase (0912)
Hydrochlorothiazide (0394)
Insulin, bovine (1637)
Insulin, porcine (1638)
Ketorolac trometamol (1755)
Lidocaine hydrochloride (0227)
Macrogol 15 hydroxystearate (2052)
Macrogol oleate (1618)
Matricaria flower (0404)
Medroxyprogesterone acetate (0673)
Metamizole sodium (1346)
Methenamine (1545)
Nadroparin calcium (1134)
Nonoxinol 9 (1454)
Noradrenaline hydrochloride (0732)
Noradrenaline tartrate (0285)
Oregano (1880)
Palmitic acid (1904)
Pancreas powder (0350)
Paraffin, hard (1034)
Parnaparin sodium (1252)
Paroxetine hydrochloride, anhydrous (2283)
Paroxetine hydrochloride hemihydrate (2018)
Pentaerythrityl tetranitrate, diluted (1355)
Pepsin powder (0682)
Perindopril *tert*-butylamine (2019)
Pholcodine (0522)
Promethazine hydrochloride (0524)
Riboflavin (0292)
Ribwort plantain (1884)
Rice starch (0349)
Sodium acetate trihydrate (0411)
Sodium calcium edetate (0231)
Sodium fluoride (0514)
Sodium hyaluronate (1472)
Squalane (1630)
Tinzaparin sodium (1271)
Trimipramine maleate (0534)
Trypsin (0694)
Urofollitropin (0958)
Urokinase (0695)
Warfarin sodium (0698)
Warfarin sodium clathrate (0699)
Yohimbine hydrochloride (2172)

CORRECTED TEXTS IN THE 6th EDITION

The texts below from the 5th Edition have been modified and specify '01/2008:XXXX-corrected 6.0' above the title. These modifications are to be taken into account from the publication date of the 6th Edition.

GENERAL CHAPTERS

2.2.20. Potentiometric titration

2.4.8. Heavy metals

2.4.15. Nickel in polyols

2.4.29. Composition of fatty acids in oils rich in omega-3 acids

2.5.12. Water: semi-micro determination

2.5.33. Total protein

2.6.13. Microbiological examination of non-sterile products: test for specified micro-organisms

2.7.2. Microbiological assay of antibiotics

2.7.6. Assay of diphtheria vaccine (adsorbed)

2.7.8. Assay of tetanus vaccine (adsorbed)

2.8.12. Determination of essential oils in herbal drugs

3.1.1.1. Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components

3.1.1.2. Materials based on plasticised poly(vinyl chloride) for tubing used in sets for the transfusion of blood and blood components

3.1.3. Polyolefines

3.1.4. Polyethylene without additives for containers for parenteral preparations and for ophthalmic preparations

3.1.5. Polyethylene with additives for containers for parenteral preparations and for ophthalmic preparations

3.1.6. Polypropylene for containers and closures for parenteral preparations and ophthalmic preparations

3.1.10. Materials based on non-plasticised poly(vinyl chloride) for containers for non-injectable, aqueous solutions

3.1.11. Materials based on non-plasticised poly(vinyl chloride) for containers for dry dosage forms for oral administration
3.1.14. Materials based on plasticised poly(vinyl chloride) for containers for aqueous solutions for intravenous infusion
3.1.15. Polyethylene terephthalate for containers for preparations not for parenteral use
3.2.2.1. Plastic containers for aqueous solutions for infusion
3.2.9. Rubber closures for containers for aqueous parenteral preparations, for powders and for freeze-dried powders
5.2.1. Terminology used in monographs on biological products
5.14. Gene transfer medicinal products for human use

MONOGRAPHS

General monographs

Herbal drugs (1433)

Vaccines for human use

Diphtheria vaccine (adsorbed) (0443)

Diphtheria, tetanus and pertussis (acellular, component) vaccine (adsorbed) (1931)

Diphtheria, tetanus, pertussis (acellular, component) and haemophilus type b conjugate vaccine (adsorbed) (1932)

Diphtheria, tetanus, pertussis (acellular, component) and hepatitis B (rDNA) vaccine (adsorbed) (1933)

Diphtheria, tetanus, pertussis (acellular, component) and poliomyelitis (inactivated) vaccine (adsorbed) (1934)

Diphtheria, tetanus, pertussis (acellular, component), hepatitis B (rDNA), poliomyelitis (inactivated) and haemophilus type b conjugate vaccine (adsorbed) (2067)

Diphtheria, tetanus, pertussis (acellular, component), poliomyelitis (inactivated) and haemophilus type b conjugate vaccine (adsorbed) (2065)

Haemophilus type b conjugate vaccine (1219)

Meningococcal group C conjugate vaccine (2112)

Pertussis vaccine (acellular, component, adsorbed) (1356)

Pertussis vaccine (acellular, co-purified, adsorbed) (1595)

Smallpox vaccine (live) (0164)

Tetanus vaccine (adsorbed) (0452)

Vaccines for veterinary use

Aujeszky's disease vaccine (live) for pigs for parenteral administration (0745)

Bovine parainfluenza virus vaccine (live) (1176)

Bovine respiratory syncytial virus vaccine (live) (1177)

Brucellosis vaccine (live) (Brucella melitensis Rev. 1 strain) for veterinary use (0793)

Canine distemper vaccine (live) (0448)

Distemper vaccine (live) for mustelids (0449)

Feline calicivirosis vaccine (live) (1102)

Infectious bovine rhinotracheitis vaccine (live) (0696)

Radiopharmaceutical preparations

Indium (^{111}In) pentetate injection (0670)

Strontium (^{89}Sr) chloride injection (1475)

Technetium (^{99m}Tc) macrosalb injection (0296)

Homoeopathic preparations

Cadmium sulphate hydrate for homoeopathic preparations (2143)

Common stinging nettle for homoeopathic preparations (2030)

Copper acetate monohydrate for homoeopathic preparations (2146)

Copper for homoeopathic preparations (1610)

Hedera helix for homoeopathic preparations (2092)

Hyoscyamus for homoeopathic preparations (2091)

Hypericum for homoeopathic preparations (2028)

Iron for homoeopathic preparations (2026)

Oriental cashew for homoeopathic preparations (2094)

Saffron for homoeopathic preparations (1624)

Monographs

Acacia (0307)

Acacia, spray-dried (0308)

Acamprosate calcium (1585)

Acebutolol hydrochloride (0871)

Aceclofenac (1281)

Acesulfame potassium (1282)

Acetazolamide (0454)

Acetylcholine chloride (1485)

Acetylcysteine (0967)

β-Acetyldigoxin (2168)

Acetylsalicylic acid (0309)

N-Acetyltryptophan (1383)

N-Acetyltyrosine (1384)

Acitretin (1385)

Adenine (0800)

Adipic acid (1586)

Agar (0310)

Agnus castus fruit (2147)

Agrimony (1587)

Alanine (0752)

Albendazole (1386)

Alchemilla (1387)

Alginic acid (0591)

Allantoin (1288)

Almagate (2010)

Aloes, Barbados (0257)

Aloes, Cape (0258)

Alprazolam (1065)

Alprenolol hydrochloride (0876)

Aluminium magnesium silicate (1388)

Aluminium oxide, hydrated (0311)

Aluminium phosphate gel (2166)

Aluminium phosphate, hydrated (1598)

Ambroxol hydrochloride (1489)

Amfetamine sulphate (0368)

Amidotrizoic acid dihydrate (0873)

Amikacin (1289)
Amikacin sulphate (1290)
Aminocaproic acid (0874)
Aminoglutethimide (1291)
Amisulpride (1490)
Ammonium bromide (1389)
Ammonium chloride (0007)
Ammonium hydrogen carbonate (1390)
Amobarbital (0594)
Amobarbital sodium (0166)
Amoxicillin sodium (0577)
Amoxicillin trihydrate (0260)
Ampicillin, anhydrous (0167)
Ampicillin sodium (0578)
Ampicillin trihydrate (0168)
Angelica root (1857)
Antazoline hydrochloride (0972)
Apomorphine hydrochloride (0136)
Arachis oil, hydrogenated (1171)
Arginine (0806)
Arginine aspartate (2096)
Arginine hydrochloride (0805)
Arnica flower (1391)
Articaine hydrochloride (1688)
Artichoke leaf (1866)
Ash leaf (1600)
Asparagine monohydrate (2086)
Aspartame (0973)
Aspartic acid (0797)
Astemizole (1067)
Atenolol (0703)
Atropine (2056)
Atropine sulphate (0068)
Azathioprine (0369)
Azelastine hydrochloride (1633)
Bacampicillin hydrochloride (0808)
Barbital (0170)
Basic butylated methacrylate copolymer (1975)
Bearberry leaf (1054)
Beclometasone dipropionate, anhydrous (0654)
Beclometasone dipropionate monohydrate (1709)
Belladonna leaf (0221)
Belladonna, prepared (0222)
Bendroflumethiazide (0370)
Benfluorex hydrochloride (1601)
Benperidol (1172)
Bentonite (0467)
Benzethonium chloride (0974)
Benzocaine (0011)
Benzoic acid (0066)
Benzoyl peroxide, hydrous (0704)
Benzylpenicillin, benzathine (0373)
Benzylpenicillin potassium (0113)
Benzylpenicillin, procaine (0115)
Benzylpenicillin sodium (0114)
Betahistine dihydrochloride (1665)
Betahistine mesilate (1071)
Betamethasone (0312)
Betamethasone dipropionate (0809)
Betamethasone valerate (0811)
Betaxolol hydrochloride (1072)
Bezafibrate (1394)
Bifonazole (1395)
Bilberry fruit, dried (1588)
Bilberry fruit, fresh (1602)
Biotin (1073)
Biperiden hydrochloride (1074)
Birch leaf (1174)
Bisacodyl (0595)
Bismuth subcarbonate (0012)
Bismuth subgallate (1493)
Bismuth subnitrate, heavy (1494)
Bismuth subsalicylate (1495)
Bitter-orange flower (1810)
Black horehound (1858)
Bleomycin sulphate (0976)
Bogbean leaf (1605)
Borax (0013)
Boric acid (0001)
Bromhexine hydrochloride (0706)
Bromperidol (1178)
Brompheniramine maleate (0977)
Brotizolam (2197)
Buckwheat herb (2184)
Budesonide (1075)
Buflomedil hydrochloride (1398)
Bumetanide (1076)
Bupivacaine hydrochloride (0541)
Buprenorphine (1180)
Buspirone hydrochloride (1711)
Butcher's broom (1847)
Caffeine (0267)
Caffeine monohydrate (0268)
Calcifediol (1295)
Calcitriol (0883)
Calcium acetate (2128)
Calcium ascorbate (1182)
Calcium carbonate (0014)
Calcium chloride dihydrate (0015)
Calcium chloride hexahydrate (0707)
Calcium folinate (0978)
Calcium glucoheptonate (1399)
Calcium gluconate (0172)
Calcium gluconate for injection (0979)
Calcium glycerophosphate (0980)

Calcium hydrogen phosphate, anhydrous (0981)
Calcium hydrogen phosphate dihydrate (0116)
Calcium lactate, anhydrous (2118)
Calcium lactate monohydrate (2117)
Calcium lactate pentahydrate (0468)
Calcium lactate trihydrate (0469)
Calcium levulinate dihydrate (1296)
Calcium pantothenate (0470)
Calcium phosphate (1052)
Calcium stearate (0882)
Calcium sulphate dihydrate (0982)
D-Camphor (1400)
Camphor, racemic (0655)
Caprylocaproyl macrogolglycerides (1184)
Capsicum (1859)
Carbachol (1971)
Carbamazepine (0543)
Carbasalate calcium (1185)
Carbidopa (0755)
Carbocisteine (0885)
Carbomers (1299)
Carboplatin (1081)
Carmellose calcium (0886)
Carmellose sodium (0472)
Carmellose sodium, low-substituted (1186)
Carteolol hydrochloride (1972)
Carvedilol (1745)
Cascara (0105)
Cefaclor (0986)
Cefadroxil monohydrate (0813)
Cefalexin monohydrate (0708)
Cefapirin sodium (1650)
Cefazolin sodium (0988)
Cefixime (1188)
Cefoperazone sodium (1404)
Cefoxitin sodium (0990)
Cefuroxime axetil (1300)
Cefuroxime sodium (0992)
Celiprolol hydrochloride (1632)
Cellulose acetate (0887)
Cellulose acetate butyrate (1406)
Cellulose acetate phthalate (0314)
Cellulose, microcrystalline (0316)
Cellulose, powdered (0315)
Centaury (1301)
Centella (1498)
Cetirizine dihydrochloride (1084)
Cetostearyl alcohol (type A), emulsifying (0801)
Cetrimide (0378)
Cetylpyridinium chloride (0379)
Chamomile flower, Roman (0380)
Charcoal, activated (0313)
Chenodeoxycholic acid (1189)
Chitosan hydrochloride (1774)
Chlorambucil (0137)
Chloramphenicol (0071)
Chloramphenicol palmitate (0473)
Chloramphenicol sodium succinate (0709)
Chlorcyclizine hydrochloride (1086)
Chlordiazepoxide (0656)
Chlorhexidine diacetate (0657)
Chlorhexidine dihydrochloride (0659)
Chlorobutanol, anhydrous (0382)
Chlorobutanol hemihydrate (0383)
Chloroquine phosphate (0544)
Chlorothiazide (0385)
Chlorphenamine maleate (0386)
Chlorpromazine hydrochloride (0475)
Chlorpropamide (1087)
Cholecalciferol concentrate (oily form) (0575)
Cholecalciferol concentrate (powder form) (0574)
Cholecalciferol concentrate (water-dispersible form) (0598)
Cimetidine (0756)
Cimetidine hydrochloride (1500)
Cinchona bark (0174)
Cinnarizine (0816)
Cisapride tartrate (1503)
Cisplatin (0599)
Citric acid, anhydrous (0455)
Citric acid monohydrate (0456)
Clarithromycin (1651)
Clazuril for veterinary use (1714)
Clebopride malate (1303)
Clemastine fumarate (1190)
Clindamycin hydrochloride (0582)
Clindamycin phosphate (0996)
Clobazam (1974)
Clobetasol propionate (2127)
Clobetasone butyrate (1090)
Clomipramine hydrochloride (0889)
Clonazepam (0890)
Clotrimazole (0757)
Cocaine hydrochloride (0073)
Codeine (0076)
Codeine phosphate hemihydrate (0074)
Codeine phosphate sesquihydrate (0075)
Cola (1504)
Colistimethate sodium (0319)
Copovidone (0891)
Coriander (1304)
Cortisone acetate (0321)
Cotton, absorbent (0036)
Cottonseed oil, hydrogenated (1305)
Couch grass rhizome (1306)
Croscarmellose sodium (0985)
Crospovidone (0892)
Cyanocobalamin (0547)
Cyclizine hydrochloride (1092)
Cyclopentolate hydrochloride (1093)
Cysteine hydrochloride monohydrate (0895)
Cystine (0998)
Dapsone (0077)

Deptropine citrate (1308)
Dequalinium chloride (1413)
Desipramine hydrochloride (0481)
Deslanoside (0482)
Desoxycortone acetate (0322)
Detomidine hydrochloride for veterinary use (1414)
Devil's claw root (1095)
Dexamethasone (0388)
Dexamethasone acetate (0548)
Dexchlorpheniramine maleate (1196)
Dextran 1 for injection (1506)
Dextromoramide tartrate (0021)
Dextropropoxyphene hydrochloride (0713)
Diazoxide (0550)
Dibrompropamidine diisetionate (2300)
Diclazuril for veterinary use (1718)
Dicloxacillin sodium (0663)
Dicycloverine hydrochloride (1197)
Dienestrol (0483)
Diethylene glycol palmitostearate (1415)
Diethylstilbestrol (0484)
Digitalis leaf (0117)
Digitoxin (0078)
Dihydroergotamine mesilate (0551)
Dihydroergotamine tartrate (0600)
Diltiazem hydrochloride (1004)
Dimenhydrinate (0601)
Dimetindene maleate (1417)
Diphenhydramine hydrochloride (0023)
Diphenoxylate hydrochloride (0819)
Dipotassium phosphate (1003)
Diprophylline (0486)
Dirithromycin (1313)
Disodium phosphate, anhydrous (1509)
Disopyramide phosphate (1005)
Dithranol (1007)
Dobutamine hydrochloride (1200)
Dog rose (1510)
Domperidone (1009)
Domperidone maleate (1008)
Dosulepin hydrochloride (1314)
Doxapram hydrochloride (1201)
Doxepin hydrochloride (1096)
Doxycycline hyclate (0272)
Doxycycline monohydrate (0820)
Droperidol (1010)
Econazole nitrate (0665)
Elder flower (1217)
Eleutherococcus (1419)
Emetine hydrochloride heptahydrate (0080)
Emetine hydrochloride pentahydrate (0081)
Enalapril maleate (1420)
Enoxolone (1511)
Ephedrine, anhydrous (0488)
Ephedrine hemihydrate (0489)
Ephedrine hydrochloride (0487)
Ephedrine hydrochloride, racemic (0715)
Equisetum stem (1825)
Ergometrine maleate (0223)
Erythromycin (0179)
Erythromycin ethylsuccinate (0274)
Erythromycin stearate (0490)
Esketamine hydrochloride (1742)
Estradiol benzoate (0139)
Estradiol valerate (1614)
Estriol (1203)
Ethacridine lactate monohydrate (1591)
Ethambutol hydrochloride (0553)
Ethinylestradiol (0140)
Ethionamide (0141)
Ethylcellulose (0822)
Etilefrine hydrochloride (1205)
Etofylline (0492)
Febantel for veterinary use (2176)
Felodipine (1013)
Fenbendazole for veterinary use (1208)
Fenbufen (1209)
Fentanyl (1210)
Fentanyl citrate (1103)
Fenticonazole nitrate (1211)
Fenugreek (1323)
Ferrous fumarate (0902)
Ferrous gluconate (0493)
Ferrous sulphate, dried (2340)
Feverfew (1516)
Finasteride (1615)
Flubendazole (1721)
Flucloxacillin sodium (0668)
Fluconazole (2287)
Flucytosine (0766)
Fludrocortisone acetate (0767)
Flumazenil (1326)
Flumequine (1517)
Flumetasone pivalate (1327)
Flunarizine dihydrochloride (1722)
Flunitrazepam (0717)
Flunixin meglumine for veterinary use (1696)
Fluocinolone acetonide (0494)
Fluocortolone pivalate (1212)
Fluorescein sodium (1213)
Flupentixol dihydrochloride (1693)
Flurazepam monohydrochloride (0905)
Fluspirilene (1723)
Flutrimazole (1424)
Fosfomycin calcium (1328)
Fosfomycin sodium (1329)
Frangula bark (0025)
Fructose (0188)
Fumitory (1869)
Furosemide (0391)
Galactose (1215)
Gallamine triethiodide (0181)

Garlic powder (1216)
Gelatin (0330)
Gentamicin sulphate (0331)
Ginkgo leaf (1828)
Ginseng (1523)
Glibenclamide (0718)
Gliclazide (1524)
Glipizide (0906)
Glucose, anhydrous (0177)
Glucose, liquid, spray-dried (1525)
Glucose monohydrate (0178)
Glutamic acid (0750)
Glutathione (1670)
Glycerol monolinoleate (1429)
Glycerol mono-oleate (1430)
Glycine (0614)
Goldenrod (1892)
Goldenrod, European (1893)
Goldenseal rhizome (1831)
Granisetron hydrochloride (1695)
Greater celandine (1861)
Griseofulvin (0182)
Guanethidine monosulphate (0027)
Guar (1218)
Guar galactomannan (0908)
Haemodialysis solutions, concentrated, water for diluting (1167)
Halofantrine hydrochloride (1979)
Haloperidol (0616)
Hamamelis leaf (0909)
Hawthorn berries (1220)
Hawthorn leaf and flower (1432)
Hawthorn leaf and flower dry extract (1865)
Heptaminol hydrochloride (1980)
Hexamidine diisetionate (1436)
Hexobarbital (0183)
Histamine dihydrochloride (0143)
Histidine (0911)
Histidine hydrochloride monohydrate (0910)
Homatropine hydrobromide (0500)
Homatropine methylbromide (0720)
Hop strobile (1222)
Human antithrombin III concentrate (0878)
Human coagulation factor VII (1224)
Human coagulation factor XI (1644)
Human haematopoietic stem cells (2323)
Hydrocortisone (0335)
Hydrocortisone acetate (0334)
Hydrocortisone hydrogen succinate (0768)
Hydromorphone hydrochloride (2099)
Hydroxocobalamin acetate (0913)
Hydroxocobalamin chloride (0914)
Hydroxocobalamin sulphate (0915)
Hydroxyethylcellulose (0336)
Hydroxypropylcellulose (0337)
Hydroxyzine hydrochloride (0916)
Hymecromone (1786)
Hyoscine butylbromide (0737)
Hypromellose (0348)
Hypromellose phthalate (0347)
Ibuprofen (0721)
Iceland moss (1439)
Ichthammol (0917)
Imipenem (1226)
Imipramine hydrochloride (0029)
Indapamide (1108)
Indian frankincense (2310)
Indometacin (0092)
Insulin aspart (2084)
Insulin, human (0838)
Insulin injection, biphasic (0831)
Insulin injection, biphasic isophane (0832)
Insulin injection, isophane (0833)
Insulin lispro (2085)
Insulin zinc injectable suspension (0837)
Insulin zinc injectable suspension (amorphous) (0835)
Insulin zinc injectable suspension (crystalline) (0836)
Iopamidol (1115)
Iopanoic acid (0700)
Iotalamic acid (0751)
Ioxaglic acid (2009)
Ipecacuanha, prepared (0093)
Ipecacuanha root (0094)
Isoconazole (1018)
Isoconazole nitrate (1017)
Isoleucine (0770)
Isoniazid (0146)
Isosorbide dinitrate, diluted (1117)
Isosorbide mononitrate, diluted (1118)
Isoxsuprine hydrochloride (1119)
Ispaghula husk (1334)
Ispaghula seed (1333)
Isradipine (2110)
Itraconazole (1335)
Ivermectin (1336)
Ivy leaf (2148)
Java tea (1229)
Josamycin propionate (1982)
Kanamycin acid sulphate (0033)
Kelp (1426)
Ketoconazole (0921)
Ketotifen hydrogen fumarate (1592)
Knotgrass (1885)
Labetalol hydrochloride (0923)
Lactitol monohydrate (1337)
Lactose, anhydrous (1061)
Lactose monohydrate (0187)
Lemon verbena leaf (1834)
Leucine (0771)
Levamisole hydrochloride (0726)
Levocabastine hydrochloride (1484)
Levocarnitine (1339)
Levodopa (0038)
Levomepromazine hydrochloride (0505)

Levomepromazine maleate (0925)
Levomethadone hydrochloride (1787)
Levonorgestrel (0926)
Levothyroxine sodium (0401)
Lime flower (0957)
Linseed (0095)
Liothyronine sodium (0728)
Liquorice root (0277)
Lisinopril dihydrate (1120)
Lithium carbonate (0228)
Loosestrife (1537)
Loperamide hydrochloride (0929)
Lorazepam (1121)
Lovage root (1233)
Lynestrenol (0558)
Lysine hydrochloride (0930)
Macrogol lauryl ether (1124)
Macrogol 6 glycerol caprylocaprate (1443)
Macrogolglycerol cocoates (1122)
Magnesium acetate tetrahydrate (2035)
Magnesium aspartate dihydrate (1445)
Magnesium carbonate, heavy (0043)
Magnesium carbonate, light (0042)
Magnesium chloride 4.5-hydrate (1341)
Magnesium chloride hexahydrate (0402)
Magnesium glycerophosphate (1446)
Magnesium hydroxide (0039)
Magnesium oxide, heavy (0041)
Magnesium oxide, light (0040)
Magnesium peroxide (1540)
Magnesium stearate (0229)
Magnesium sulphate heptahydrate (0044)
Magnesium trisilicate (0403)
Maleic acid (0365)
Malic acid (2080)
Mallow flower (1541)
Maltitol (1235)
Maltodextrin (1542)
Manganese sulphate monohydrate (1543)
Marshmallow leaf (1856)
Marshmallow root (1126)
Meadowsweet (1868)
Mebendazole (0845)
Mefenamic acid (1240)
Megestrol acetate (1593)
Meglumine (2055)
Melilot (2120)
Melissa leaf (1447)
Mepivacaine hydrochloride (1242)
Mepyramine maleate (0278)
Mercuric chloride (0120)
Mesalazine (1699)
Mesterolone (1730)
Mestranol (0509)
Metformin hydrochloride (0931)
Methacrylic acid - ethyl acrylate copolymer (1:1) (1128)
Methacrylic acid - ethyl acrylate copolymer (1:1) dispersion 30 per cent (1129)
Methacrylic acid - methyl methacrylate copolymer (1:1) (1127)
Methacrylic acid - methyl methacrylate copolymer (1:2) (1130)
Methadone hydrochloride (0408)
Methaqualone (0510)
Methionine (1027)
DL-Methionine (0624)
Methyl parahydroxybenzoate (0409)
Methylatropine bromide (0511)
Methylatropine nitrate (0512)
Methylcellulose (0345)
Methylhydroxyethylcellulose (0346)
Methylphenobarbital (0189)
Methylprednisolone (0561)
Methylprednisolone acetate (0933)
Methylprednisolone hydrogen succinate (1131)
Methyltestosterone (0410)
Methylthioninium chloride (1132)
Metoclopramide (1348)
Metolazone (1757)
Metoprolol succinate (1448)
Metoprolol tartrate (1028)
Metrifonate (1133)
Metronidazole (0675)
Miconazole nitrate (0513)
Midazolam (0936)
Milk-thistle fruit (1860)
Minocycline hydrochloride dihydrate (1030)
Minoxidil (0937)
Modafinil (2307)
Mometasone furoate (1449)
Morantel hydrogen tartrate for veterinary use (1546)
Motherwort (1833)
Moxonidine (1758)
Mullein flower (1853)
Mupirocin (1450)
Mupirocin calcium (1451)
Myrrh (1349)
Naftidrofuryl hydrogen oxalate (1594)
Nalidixic acid (0701)
Naphazoline hydrochloride (0730)
Naphazoline nitrate (0147)
Naproxen (0731)
Narrow-leaved coneflower root (1821)
Neostigmine bromide (0046)
Neostigmine metilsulfate (0626)
Netilmicin sulphate (1351)
Nettle leaf (1897)
Nevirapine, anhydrous (2255)
Niclosamide, anhydrous (0679)
Niclosamide monohydrate (0680)
Nicotinamide (0047)
Nicotinic acid (0459)
Nifedipine (0627)

Nifuroxazide (1999)
Nimesulide (1548)
Nimodipine (1245)
Nitrazepam (0415)
Nitrendipine (1246)
Nitrofural (1135)
Nitrofurantoin (0101)
Nizatidine (1453)
Nomegestrol acetate (1551)
Norethisterone (0234)
Norethisterone acetate (0850)
Norfloxacin (1248)
Norgestrel (0940)
Nortriptyline hydrochloride (0941)
Noscapine (0516)
Noscapine hydrochloride (0515)
Oak bark (1887)
Ofloxacin (1455)
Olive leaf (1878)
Olsalazine sodium (1457)
Opium dry extract, standardised (1839)
Opium, prepared (1840)
Opium, raw (0777)
Opium tincture, standardised (1841)
Orphenadrine citrate (1759)
Orphenadrine hydrochloride (1760)
Ouabain (0048)
Oxaliplatin (2017)
Oxazepam (0778)
Oxfendazole for veterinary use (1458)
Oxitropium bromide (2170)
Oxolinic acid (1353)
Oxprenolol hydrochloride (0628)
Oxybuprocaine hydrochloride (1251)
Oxybutynin hydrochloride (1354)
Oxymetazoline hydrochloride (0943)
Oxytocin (0780)
Paclitaxel (1794)
Pale coneflower root (1822)
Papaverine hydrochloride (0102)
Paracetamol (0049)
Passion flower (1459)
Pelargonium root (2264)
Penbutolol sulphate (1461)
Penicillamine (0566)
Pentamidine diisetionate (1137)
Pentazocine lactate (2000)
Pentobarbital (0200)
Pentobarbital sodium (0419)
Pergolide mesilate (1555)
Pethidine hydrochloride (0420)
Pheniramine maleate (1357)
Phenobarbital (0201)
Phenobarbital sodium (0630)
Phenolphthalein (1584)
Phenolsulfonphthalein (0242)
Phenoxymethylpenicillin (0148)
Phentolamine mesilate (1138)
Phenylalanine (0782)
Phenylephrine (1035)
Phenylephrine hydrochloride (0632)
Phenylpropanolamine hydrochloride (0683)
Phenytoin (1253)
Phenytoin sodium (0521)
Phthalylsulfathiazole (0352)
Physostigmine salicylate (0286)
Physostigmine sulphate (0684)
Phytosterol (1911)
Pilocarpine hydrochloride (0633)
Pilocarpine nitrate (0104)
Pimozide (1254)
Pindolol (0634)
Pipemidic acid trihydrate (1743)
Piperacillin (1169)
Piperacillin sodium (1168)
Piperazine adipate (0423)
Piperazine citrate (0424)
Piracetam (1733)
Piretanide (1556)
Piroxicam (0944)
Pivampicillin (0852)
Pivmecillinam hydrochloride (1359)
Polyacrylate dispersion 30 per cent (0733)
Poly(vinyl acetate) (1962)
Poly(vinyl acetate) dispersion 30 per cent (2152)
Poly(vinyl alcohol) (1961)
Potassium acetate (1139)
Potassium bromide (0184)
Potassium carbonate (1557)
Potassium chloride (0185)
Potassium citrate (0400)
Potassium dihydrogen phosphate (0920)
Potassium hydrogen aspartate hemihydrate (2076)
Potassium hydrogen carbonate (1141)
Potassium hydrogen tartrate (1984)
Potassium hydroxide (0840)
Potassium iodide (0186)
Potassium metabisulphite (2075)
Potassium nitrate (1465)
Potassium perchlorate (1987)
Potassium sodium tartrate tetrahydrate (1986)
Potassium sorbate (0618)
Potassium sulphate (1622)
Potato starch (0355)
Povidone, iodinated (1142)
Pravastatin sodium (2059)
Prazepam (1466)
Prazosin hydrochloride (0856)
Prednicarbate (1467)
Prednisolone (0353)
Prednisolone acetate (0734)
Prednisolone pivalate (0736)

Prednisone (0354)
Prilocaine hydrochloride (1363)
Primaquine diphosphate (0635)
Primidone (0584)
Primula root (1364)
Probenecid (0243)
Procainamide hydrochloride (0567)
Procaine hydrochloride (0050)
Prochlorperazine maleate (0244)
Progesterone (0429)
Proguanil hydrochloride (2002)
Proline (0785)
Promazine hydrochloride (1365)
Propacetamol hydrochloride (1366)
Propafenone hydrochloride (2103)
Propantheline bromide (0857)
Propranolol hydrochloride (0568)
Propyl gallate (1039)
Propyl parahydroxybenzoate (0431)
Propylthiouracil (0525)
Protamine hydrochloride (0686)
Protamine sulphate (0569)
Proxyphylline (0526)
Pseudoephedrine hydrochloride (1367)
Psyllium seed (0858)
Purple coneflower herb (1823)
Purple coneflower root (1824)
Pygeum africanum bark (1886)
Pyrantel embonate (1680)
Pyrazinamide (0859)
Pyridostigmine bromide (1255)
Pyridoxine hydrochloride (0245)
Pyrimethamine (0288)
Quinine hydrochloride (0018)
Quinine sulphate (0019)
Ramipril (1368)
Red poppy petals (1881)
Repaglinide (2135)
Restharrow root (1879)
Rhatany root (0289)
Rhubarb (0291)
Ribavirin (2109)
Riboflavin sodium phosphate (0786)
Rifabutin (1657)
Risperidone (1559)
Roselle (1623)
Roxithromycin (1146)
Salbutamol (0529)
Salbutamol sulphate (0687)
Salicylic acid (0366)
Saw palmetto fruit (1848)
Senna leaf (0206)
Senna pods, Alexandrian (0207)
Senna pods, Tinnevelly (0208)
Serine (0788)
Silica, colloidal anhydrous (0434)
Silica, colloidal hydrated (0738)
Silica, dental type (1562)
Silica, hydrophobic colloidal (2208)
Silver, colloidal, for external use (2281)
Silver nitrate (0009)
Sodium alginate (0625)
Sodium aminosalicylate dihydrate (1993)
Sodium ascorbate (1791)
Sodium aurothiomalate (1994)
Sodium benzoate (0123)
Sodium bromide (0190)
Sodium caprylate (1471)
Sodium chloride (0193)
Sodium citrate (0412)
Sodium cromoglicate (0562)
Sodium cyclamate (0774)

Zinc chloride (0110)
Zinc oxide (0252)
Zinc stearate (0306)
Zinc sulphate heptahydrate (0111)
Zinc sulphate hexahydrate (1683)
Zinc undecylenate (0539)

TEXTS WHOSE TITLE HAS CHANGED FOR THE 6th EDITION

The titles of the following texts have been changed in the 6th Edition.

GENERAL CHAPTERS

2.8.12. Determination of essential oils in herbal drugs *(previously Determination of essential oils in vegetable drugs)*

3.2.2.1. Plastic containers for aqueous solutions for infusion *(previously Plastic containers for aqueous solutions for parenteral infusion)*

5.2.1. Terminology used in monographs on biological products *(previously Terminology used in monographs on vaccines)*

MONOGRAPHS

Vaccines for veterinary use

Aujeszky's disease vaccine (live) for pigs for parenteral administration (0745) *(previously Aujeszky's disease vaccine (live) for pigs for parenteral administration, freeze-dried)*

Bovine parainfluenza virus vaccine (live) (1176) *(previously Bovine parainfluenza virus vaccine (live), freeze-dried)*

Bovine respiratory syncytial virus vaccine (live) (1177) *(previously Bovine respiratory syncytial virus vaccine (live), freeze-dried)*

Brucellosis vaccine (live) (Brucella melitensis Rev. 1 strain) for veterinary use (0793) *(previously Brucellosis vaccine (live) (Brucella melitensis Rev. 1 strain), freeze-dried, for veterinary use)*

Canine distemper vaccine (live) (0448) *(previously Canine distemper vaccine (live), freeze-dried)*

Distemper vaccine (live) for mustelids (0449) *(previously Distemper vaccine (live) for mustelids, freeze-dried)*

Feline calicivirosis vaccine (live) (1102) *(previously Feline calicivirosis vaccine (live), freeze-dried)*

Infectious bovine rhinotracheitis vaccine (live) (0696) *(previously Infectious bovine rhinotracheitis vaccine (live), freeze-dried)*

Monographs

Pine sylvestris oil (1842) *(previously pine silvestris oil)*

Silica, hydrophobic colloidal (2208) *(previously Silica, hydrophobic colloidal anhydrous)*

TEXTS DELETED FOR THE 6th EDITION

The following texts are deleted as of ***1 January 2008****.*

GENERAL CHAPTERS

2.9.24. Resistance to rupture of suppositories and pessaries

2.9.28. Test for deliverable mass or volume of liquid and semi-solid preparations

MONOGRAPHS

Monographs

Acriflavinium monochloride (2043)

ERRATA

In the following monographs, after the heading ‘Other detectable impurities’ in the Impurities section, read:

‘(the following substances would, if present at a sufficient level, be detected by one or other of the tests in the monograph. They are limited by the general acceptance criterion for other/unspecified impurities and/or by the general monograph *Substances for pharmaceutical use (2034)*. It is therefore not necessary to identify these impurities for demonstration of compliance. See also *5.10. Control of impurities in substances for pharmaceutical use*)’

Articaine hydrochloride (1688)
Biperiden hydrochloride (1074)
Caffeine (0267)
Caffeine monohydrate (0268)
Ibuprofen (0721)
Ifosfamide (1529)
Metformin hydrochloride (0931)
Naphazoline hydrochloride (0730)
Norethisterone acetate (0850)
Oxaliplatin (2017)
Potassium clavulanate (1140)
Potassium clavulanate, diluted (1653)
Testosterone propionate (0297)
Thiamine hydrochloride (0303)
Thiamine nitrate (0531)
Tranexamic acid (0875)

1. GENERAL NOTICES

1. General notices.. 3

01/2008:10000

1. GENERAL NOTICES

1.1. GENERAL STATEMENTS

The General Notices apply to all monographs and other texts of the European Pharmacopoeia.

The official texts of the European Pharmacopoeia are published in English and French. Translations in other languages may be prepared by the signatory States of the European Pharmacopoeia Convention. In case of doubt or dispute, the English and French versions are alone authoritative.

In the texts of the European Pharmacopoeia, the word 'Pharmacopoeia' without qualification means the European Pharmacopoeia. The official abbreviation Ph. Eur. may be used to indicate the European Pharmacopoeia.

The use of the title or the subtitle of a monograph implies that the article complies with the requirements of the relevant monograph. Such references to monographs in the texts of the Pharmacopoeia are shown using the monograph title and reference number in *italics*.

A preparation must comply throughout its period of validity; a distinct period of validity and/or specifications for opened or broached containers may be decided by the competent authority. The subject of any other monograph must comply throughout its period of use. The period of validity that is assigned to any given article and the time from which that period is to be calculated are decided by the competent authority in the light of experimental results of stability studies.

Unless otherwise indicated in the General Notices or in the monographs, statements in monographs constitute mandatory requirements. General chapters become mandatory when referred to in a monograph, unless such reference is made in a way that indicates that it is not the intention to make the text referred to mandatory but rather to cite it for information.

The active ingredients (medicinal substances), excipients (auxiliary substances), pharmaceutical preparations and other articles described in the monographs are intended for human and veterinary use (unless explicitly restricted to one of these uses). An article is not of Pharmacopoeia quality unless it complies with all the requirements stated in the monograph. This does not imply that performance of all the tests in a monograph is necessarily a prerequisite for a manufacturer in assessing compliance with the Pharmacopoeia before release of a product. The manufacturer may obtain assurance that a product is of Pharmacopoeia quality from data derived, for example, from validation studies of the manufacturing process and from in-process controls. Parametric release in circumstances deemed appropriate by the competent authority is thus not precluded by the need to comply with the Pharmacopoeia.

The tests and assays described are the official methods upon which the standards of the Pharmacopoeia are based. With the agreement of the competent authority, alternative methods of analysis may be used for control purposes, provided that the methods used enable an unequivocal decision to be made as to whether compliance with the standards of the monographs would be achieved if the official methods were used. In the event of doubt or dispute, the methods of analysis of the Pharmacopoeia are alone authoritative.

Certain materials that are the subject of a pharmacopoeial monograph may exist in different grades suitable for different purposes. Unless otherwise indicated in the monograph, the requirements apply to all grades of the material. In some monographs, particularly those on excipients, a list of functionality-related characteristics that are relevant to the use of the substance may be appended to the monograph for information. Test methods for determination of one or more of these characteristics may be given, also for information.

Quality systems. The quality standards represented by monographs are valid only where the articles in question are produced within the framework of a suitable quality system.

General monographs. Substances and preparations that are the subject of an individual monograph are also required to comply with relevant, applicable general monographs. Cross-references to applicable general monographs are not normally given in individual monographs.

General monographs apply to all substances and preparations within the scope of the Definition section of the general monograph, except where a preamble limits the application, for example to substances and preparations that are the subject of a monograph of the Pharmacopoeia.

General monographs on dosage forms apply to all preparations of the type defined. The requirements are not necessarily comprehensive for a given specific preparation and requirements additional to those prescribed in the general monograph may be imposed by the competent authority.

General monographs and individual monographs are complementary. If the provisions of a general monograph do not apply to a particular product, this is expressly stated in the individual monograph.

Validation of pharmacopoeial methods. The test methods given in monographs and general chapters have been validated in accordance with accepted scientific practice and current recommendations on analytical validation. Unless otherwise stated in the monograph or general chapter, validation of the test methods by the analyst is not required.

Conventional terms. The term 'competent authority' means the national, supranational or international body or organisation vested with the authority for making decisions concerning the issue in question. It may, for example, be a national pharmacopoeia authority, a licensing authority or an official control laboratory.

The expression 'unless otherwise justified and authorised' means that the requirements have to be met, unless the competent authority authorises a modification or an exemption where justified in a particular case.

Statements containing the word 'should' are informative or advisory.

In certain monographs or other texts, the terms 'suitable' and 'appropriate' are used to describe a reagent, micro-organism, test method etc.; if criteria for suitability are not described in the monograph, suitability is demonstrated to the satisfaction of the competent authority.

Interchangeable methods. Certain general chapters contain a statement that the text in question is harmonised with the corresponding text of the Japanese Pharmacopoeia and/or the United States Pharmacopeia and that these texts are interchangeable. This implies that if a substance or preparation is found to comply with a requirement using an interchangeable method from one of these pharmacopoeias it complies with the requirements of the European Pharmacopoeia. In the event of doubt or dispute, the text of the European Pharmacopoeia is alone authoritative.

References to regulatory documents. Monographs and general chapters may contain references to documents issued by regulatory authorities for medicines, for example directives and notes for guidance of the European Union.

These references are provided for information for users for the Pharmacopoeia. Inclusion of such a reference does not modify the status of the documents referred to, which may be mandatory or for guidance.

1.2. OTHER PROVISIONS APPLYING TO GENERAL CHAPTERS AND MONOGRAPHS

Quantities. In tests with numerical limits and assays, the quantity stated to be taken for examination is approximate. The amount actually used, which may deviate by not more than 10 per cent from that stated, is accurately weighed or measured and the result is calculated from this exact quantity. In tests where the limit is not numerical, but usually depends upon comparison with the behaviour of a reference substance in the same conditions, the stated quantity is taken for examination. Reagents are used in the prescribed amounts.

Quantities are weighed or measured with an accuracy commensurate with the indicated degree of precision. For weighings, the precision corresponds to plus or minus 5 units after the last figure stated (for example, 0.25 g is to be interpreted as 0.245 g to 0.255 g). For the measurement of volumes, if the figure after the decimal point is a zero or ends in a zero (for example, 10.0 ml or 0.50 ml), the volume is measured using a pipette, a volumetric flask or a burette, as appropriate; otherwise, a graduated measuring cylinder or a graduated pipette may be used. Volumes stated in microlitres are measured using a micropipette or microsyringe.

It is recognised, however, that in certain cases the precision with which quantities are stated does not correspond to the number of significant figures stated in a specified numerical limit. The weighings and measurements are then carried out with a sufficiently improved accuracy.

Apparatus and procedures. Volumetric glassware complies with Class A requirements of the appropriate International Standard issued by the International Organisation for Standardisation.

Unless otherwise prescribed, analytical procedures are carried out at a temperature between 15 °C and 25 °C.

Unless otherwise prescribed, comparative tests are carried out using identical tubes of colourless, transparent, neutral glass with a flat base; the volumes of liquid prescribed are for use with tubes having an internal diameter of 16 mm, but tubes with a larger internal diameter may be used provided the volume of liquid used is adjusted (*2.1.5*). Equal volumes of the liquids to be compared are examined down the vertical axis of the tubes against a white background, or if necessary against a black background. The examination is carried out in diffuse light.

Any solvent required in a test or assay in which an indicator is to be used is previously neutralised to the indicator, unless a blank test is prescribed.

Water-bath. The term 'water-bath' means a bath of boiling water unless water at another temperature is indicated. Other methods of heating may be substituted provided the temperature is near to but not higher than 100 °C or the indicated temperature.

Drying and ignition to constant mass. The terms 'dried to constant mass' and 'ignited to constant mass' mean that 2 consecutive weighings do not differ by more than 0.5 mg, the 2nd weighing following an additional period of drying or of ignition respectively appropriate to the nature and quantity of the residue.

Where drying is prescribed using one of the expressions 'in a desiccator' or '*in vacuo*', it is carried out using the conditions described in chapter *2.2.32. Loss on drying*.

Reagents. The proper conduct of the analytical procedures described in the Pharmacopoeia and the reliability of the results depend, in part, upon the quality of the reagents used. The reagents are described in general chapter *4*. It is assumed that reagents of analytical grade are used; for some reagents, tests to determine suitability are included in the specifications.

Solvents. Where the name of the solvent is not stated, the term 'solution' implies a solution in water.

Where the use of water is specified or implied in the analytical procedures described in the Pharmacopoeia or for the preparation of reagents, water complying with the requirements of the monograph *Purified water (0008)* is used, except that for many purposes the requirements for bacterial endotoxins (*Purified water in bulk*) and microbial contamination (*Purified water in containers)* are not relevant. The term 'distilled water' indicates purified water prepared by distillation.

The term 'ethanol' without qualification means anhydrous ethanol. The term 'alcohol' without qualification means ethanol (96 per cent). Other dilutions of ethanol are indicated by the term 'ethanol' or 'alcohol' followed by a statement of the percentage by volume of ethanol (C_2H_6O) required.

Expression of content. In defining content, the expression 'per cent' is used according to circumstances with one of 2 meanings:

- per cent *m/m* (percentage, mass in mass) expresses the number of grams of substance in 100 grams of final product;
- per cent *V/V* (percentage, volume in volume) expresses the number of millilitres of substance in 100 millilitres of final product.

The expression 'parts per million' (or ppm) refers to mass in mass, unless otherwise specified.

Temperature. Where an analytical procedure describes temperature without a figure, the general terms used have the following meaning:

- in a deep-freeze: below – 15 °C;
- in a refrigerator: 2 °C to 8 °C;
- cold or cool: 8 °C to 15 °C;
- room temperature: 15 °C to 25 °C.

1.3. GENERAL CHAPTERS

Containers. Materials used for containers are described in general chapter *3.1*. General names used for materials, particularly plastic materials, each cover a range of products varying not only in the properties of the principal constituent but also in the additives used. The test methods and limits for materials depend on the formulation and are therefore applicable only for materials whose formulation is covered by the preamble to the specification. The use of materials with different formulations, and the test methods and limits applied to them, are subject to agreement by the competent authority.

The specifications for containers in general chapter *3.2* have been developed for general application to containers of the stated category, but in view of the wide variety of containers available and possible new developments, the publication of a specification does not exclude the use, in justified circumstances, of containers that comply with other specifications, subject to agreement by the competent authority.

Reference may be made within the monographs of the Pharmacopoeia to the definitions and specifications for containers provided in chapter *3.2. Containers*. The general

monographs for pharmaceutical dosage forms may, under the heading Definition/Production, require the use of certain types of container; certain other monographs may, under the heading Storage, indicate the type of container that is recommended for use.

1.4. MONOGRAPHS

TITLES

Monograph titles are in English and French in the respective versions and there is a Latin subtitle.

RELATIVE ATOMIC AND MOLECULAR MASSES

The relative atomic mass (A_r) or the relative molecular mass (M_r) is shown, as and where appropriate, at the beginning of each monograph. The relative atomic and molecular masses and the molecular and graphic formulae do not constitute analytical standards for the substances described.

CHEMICAL ABSTRACTS SERVICE (CAS) REGISTRY NUMBER

CAS registry numbers are included for information in monographs, where applicable, to provide convenient access to useful information for users. CAS Registry Number® is a Registered Trademark of the American Chemical Society.

DEFINITION

Statements under the heading Definition constitute an official definition of the substance, preparation or other article that is the subject of the monograph.

Limits of content. Where limits of content are prescribed, they are those determined by the method described under Assay.

Herbal drugs. In monographs on herbal drugs, the definition indicates whether the subject of the monograph is, for example, the whole drug or the drug in powdered form. Where a monograph applies to the drug in several states, for example both to the whole drug and the drug in powdered form, the definition states this.

PRODUCTION

Statements under the heading Production draw attention to particular aspects of the manufacturing process but are not necessarily comprehensive. They constitute mandatory requirements for manufacturers, unless otherwise stated. They may relate, for example, to source materials; to the manufacturing process itself and its validation and control; to in-process testing; or to testing that is to be carried out by the manufacturer on the final article, either on selected batches or on each batch prior to release. These statements cannot necessarily be verified on a sample of the final article by an independent analyst. The competent authority may establish that the instructions have been followed, for example, by examination of data received from the manufacturer, by inspection of manufacture or by testing appropriate samples.

The absence of a Production section does not imply that attention to features such as those referred to above is not required.

Choice of vaccine strain, Choice of vaccine composition. The Production section of a monograph may define the characteristics of a vaccine strain or vaccine composition. Unless otherwise stated, test methods given for verification of these characteristics are provided for information as examples of suitable methods. Subject to approval by the competent authority, other test methods may be used without validation against the method shown in the monograph.

CHARACTERS

The statements under the heading Characters are not to be interpreted in a strict sense and are not requirements.

Solubility. In statements of solubility in the Characters section, the terms used have the following significance, referred to a temperature between 15 °C and 25 °C.

Descriptive term	Approximate volume of solvent in millilitres per gram of solute			
Very soluble	less than	1		
Freely soluble	from	1	to	10
Soluble	from	10	to	30
Sparingly soluble	from	30	to	100
Slightly soluble	from	100	to	1000
Very slightly soluble	from	1000	to	10 000
Practically insoluble	more than			10 000

The term ‘partly soluble’ is used to describe a mixture where only some of the components dissolve. The term ‘miscible’ is used to describe a liquid that is miscible in all proportions with the stated solvent.

IDENTIFICATION

Scope. The tests given in the Identification section are not designed to give a full confirmation of the chemical structure or composition of the product; they are intended to give confirmation, with an acceptable degree of assurance, that the article conforms to the description on the label.

First and second identifications. Certain monographs have subdivisions entitled ‘First identification’ and ‘Second identification’. The test or tests that constitute the ‘First identification’ may be used for identification in all circumstances. The test or tests that constitute the ‘Second identification’ may be used for identification provided it can be demonstrated that the substance or preparation is fully traceable to a batch certified to comply with all the other requirements of the monograph.

Powdered herbal drugs. Monographs on herbal drugs may contain schematic drawings of the powdered drug. These drawings complement the description given in the relevant identification test.

TESTS AND ASSAYS

Scope. The requirements are not framed to take account of all possible impurities. It is not to be presumed, for example, that an impurity that is not detectable by means of the prescribed tests is tolerated if common sense and good pharmaceutical practice require that it be absent. See also below under Impurities.

Calculation. Where the result of a test or assay is required to be calculated with reference to the dried or anhydrous substance or on some other specified basis, the determination of loss on drying, water content or other property is carried out by the method prescribed in the relevant test in the monograph. The words ‘dried substance’ or ‘anhydrous substance’ etc. appear in parentheses after the result.

Limits. The limits prescribed are based on data obtained in normal analytical practice; they take account of normal analytical errors, of acceptable variations in manufacture and compounding and of deterioration to an extent considered acceptable. No further tolerances are to be applied to the limits prescribed to determine whether the article being examined complies with the requirements of the monograph.

In determining compliance with a numerical limit, the calculated result of a test or assay is first rounded to the

number of significant figures stated, unless otherwise prescribed. The last figure is increased by one when the part rejected is equal to or exceeds one half-unit, whereas it is not modified when the part rejected is less than a half-unit.

Indication of permitted limit of impurities. For comparative tests, the approximate content of impurity tolerated, or the sum of impurities, may be indicated for information only. Acceptance or rejection is determined on the basis of compliance or non-compliance with the stated test. If the use of a reference substance for the named impurity is not prescribed, this content may be expressed as a nominal concentration of the substance used to prepare the reference solution specified in the monograph, unless otherwise described.

Herbal drugs. For herbal drugs, the sulphated ash, total ash, water-soluble matter, alcohol-soluble matter, water content, content of essential oil and content of active principle are calculated with reference to the drug that has not been specially dried, unless otherwise prescribed in the monograph.

Equivalents. Where an equivalent is given, for the purposes of the Pharmacopoeia only the figures shown are to be used in applying the requirements of the monograph.

Culture media. The culture media described in monographs and general chapters have been found to be satisfactory for the intended purpose. However, the components of media, particularly those of biological origin, are of variable quality, and it may be necessary for optimal performance to modulate the concentration of some ingredients, notably:

- peptones and meat or yeast extracts, with respect to their nutritive properties;
- buffering substances;
- bile salts, bile extract, deoxycholate, and colouring matter, depending on their selective properties;
- antibiotics, with respect to their activity.

STORAGE

The information and recommendations given under the heading Storage do not constitute a pharmacopoeial requirement but the competent authority may specify particular storage conditions that must be met.

The articles described in the Pharmacopoeia are stored in such a way as to prevent contamination and, as far as possible, deterioration. Where special conditions of storage are recommended, including the type of container (see section 1.3. General chapters) and limits of temperature, they are stated in the monograph.

The following expressions are used in monographs under Storage with the meaning shown.

In an airtight container means that the product is stored in an airtight container (*3.2*). Care is to be taken when the container is opened in a damp atmosphere. A low moisture content may be maintained, if necessary, by the use of a desiccant in the container provided that direct contact with the product is avoided.

Protected from light means that the product is stored either in a container made of a material that absorbs actinic light sufficiently to protect the contents from change induced by such light, or in a container enclosed in an outer cover that provides such protection, or is stored in a place from which all such light is excluded.

LABELLING

In general, labelling of medicines is subject to supranational and national regulation and to international agreements. The statements under the heading Labelling are not therefore comprehensive and, moreover, for the purposes of the Pharmacopoeia only those statements that are necessary to demonstrate compliance or non-compliance with the monograph are mandatory. Any other labelling statements are included as recommendations. When the term 'label' is used in the Pharmacopoeia, the labelling statements may appear on the container, the package, a leaflet accompanying the package, or a certificate of analysis accompanying the article, as decided by the competent authority.

WARNINGS

Materials described in monographs and reagents specified for use in the Pharmacopoeia may be injurious to health unless adequate precautions are taken. The principles of good quality control laboratory practice and the provisions of any appropriate regulations are to be observed at all times. Attention is drawn to particular hazards in certain monographs by means of a warning statement; absence of such a statement is not to be taken to mean that no hazard exists.

IMPURITIES

A list of all known and potential impurities that have been shown to be detected by the tests in a monograph may be given. See also chapter *5.10. Control of impurities in substances for pharmaceutical use*. The impurities are designated by a letter or letters of the alphabet. Where a letter appears to be missing, the impurity designated by this letter has been deleted from the list during monograph development prior to publication or during monograph revision.

FUNCTIONALITY-RELATED CHARACTERISTICS OF EXCIPIENTS

Monographs on excipients may have a section on functionality-related characteristics. The characteristics, any test methods for determination and any tolerances are not mandatory requirements; they may nevertheless be relevant for use of the excipient and are given for information (see also section 1.1. General statements).

REFERENCE STANDARDS

Certain monographs require the use of reference standards (chemical reference substances, biological reference preparations, reference spectra). See also chapter *5.12. Reference standards*. The European Pharmacopoeia Commission establishes the official reference standards, which are alone authoritative in case of arbitration. These reference standards are available from the European Directorate for the Quality of Medicines & HealthCare (EDQM). Information on the available reference standards and a batch validity statement can be obtained via the EDQM website.

1.5. ABBREVIATIONS AND SYMBOLS

A	Absorbance
$A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}}$	Specific absorbance
A_r	Relative atomic mass
$[\alpha]_\mathrm{D}^{20}$	Specific optical rotation
bp	Boiling point
BRP	Biological Reference Preparation
CRS	Chemical Reference Substance
d_{20}^{20}	Relative density
IU	International Unit
λ	Wavelength
M	Molarity
M_r	Relative molecular mass

mp	Melting point
n_D^{20}	Refractive index
Ph. Eur. U.	European Pharmacopoeia Unit
ppm	Parts per million
R	Substance or solution defined under *4. Reagents*
R_F	Retardation factor (see chapter *2.2.46*)
R_{st}	Used in chromatography to indicate the ratio of the distance travelled by .a substance to the distance travelled by a reference substance
RV	Substance used as a primary standard in volumetric analysis (chapter *4.2.1*)

Abbreviations used in the monographs on immunoglobulins, immunosera and vaccines

LD_{50}	The statistically determined quantity of a substance that, when administered by the specified route, may be expected to cause the death of 50 per cent of the test animals within a given period
MLD	Minimum lethal dose
L+/10 dose	The smallest quantity of a toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, causes the death of the test animals within a given period
L+ dose	The smallest quantity of a toxin that, in the conditions of the test, when mixed with 1 IU of antitoxin and administered by the specified route, causes the death of the test animals within a given period
lr/100 dose	The smallest quantity of a toxin that, in the conditions of the test, when mixed with 0.01 IU of antitoxin and injected intracutaneously causes a characteristic reaction at the site of injection within a given period
Lp/10 dose	The smallest quantity of toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, causes paralysis in the test animals within a given period
Lo/10 dose	The largest quantity of a toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, does not cause symptoms of toxicity in the test animals within a given period
Lf dose	The quantity of toxin or toxoid that flocculates in the shortest time with 1 IU of antitoxin
$CCID_{50}$	The statistically determined quantity of virus that may be expected to infect 50 per cent of the cell cultures to which it is added
EID_{50}	The statistically determined quantity of virus that may be expected to infect 50 per cent of the fertilised eggs into which it is inoculated
ID_{50}	The statistically determined quantity of a virus that may be expected to infect 50 per cent of the animals into which it is inoculated
PD_{50}	The statistically determined dose of a vaccine that, in the conditions of the test, may be expected to protect 50 per cent of the animals against a challenge dose of the micro-organisms or toxins against which it is active
ED_{50}	The statistically determined dose of a vaccine that, in the conditions of the test, may be expected to induce specific antibodies in 50 per cent of the animals for the relevant vaccine antigens
PFU	Pock-forming units or plaque-forming units
SPF	Specified-pathogen-free.

1.6. UNITS OF THE INTERNATIONAL SYSTEM (SI) USED IN THE PHARMACOPOEIA AND EQUIVALENCE WITH OTHER UNITS

INTERNATIONAL SYSTEM OF UNITS (SI)

The International System of Units comprises 3 classes of units, namely base units, derived units and supplementary units[(1)]. The base units and their definitions are set out in Table 1.6-1.

The derived units may be formed by combining the base units according to the algebraic relationships linking the corresponding quantities. Some of these derived units have special names and symbols. The SI units used in the European Pharmacopoeia are shown in Table 1.6-2.

Some important and widely used units outside the International System are shown in Table 1.6-3.

The prefixes shown in Table 1.6-4 are used to form the names and symbols of the decimal multiples and submultiples of SI units.

NOTES

1. In the Pharmacopoeia, the Celsius temperature is used (symbol *t*). This is defined by the equation:

$$t = T - T_0$$

where T_0 = 273.15 K by definition. The Celsius or centigrade temperature is expressed in degrees Celsius (symbol °C). The unit 'degree Celsius' is equal to the unit 'kelvin'.

2. The practical expressions of concentrations used in the Pharmacopoeia are defined in the General Notices.

3. The radian is the plane angle between two radii of a circle that cut off on the circumference an arc equal in length to the radius.

4. In the Pharmacopoeia, conditions of centrifugation are defined by reference to the acceleration due to gravity (*g*):

$$g = 9.806\,65\ m \cdot s^{-2}$$

5. Certain quantities without dimensions are used in the Pharmacopoeia: relative density (*2.2.5*), absorbance (*2.2.25*), specific absorbance (*2.2.25*) and refractive index (*2.2.6*).

6. The microkatal is defined as the enzymic activity that, under defined conditions, produces the transformation (e.g. hydrolysis) of 1 micromole of the substrate per second.

Table 1.6.-1. – *SI base units*

Quantity		Unit		Definition
Name	**Symbol**	**Name**	**Symbol**	
Length	*l*	metre	m	The metre is the length of the path travelled by light in a vacuum during a time interval of 1/299 792 458 of a second.
Mass	*m*	kilogram	kg	The kilogram is equal to the mass of the international prototype of the kilogram.
Time	*t*	second	s	The second is the duration of 9 192 631 770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the caesium-133 atom.
Electric current	*I*	ampere	A	The ampere is that constant current which, maintained in two straight parallel conductors of infinite length, of negligible circular cross-section and placed 1 metre apart in vacuum would produce between these conductors a force equal to 2×10^{-7} newton per metre of length.
Thermodynamic temperature	*T*	kelvin	K	The kelvin is the fraction 1/273.16 of the thermodynamic temperature of the triple point of water.
Amount of substance	*n*	mole	mol	The mole is the amount of substance of a system containing as many elementary entities as there are atoms in 0.012 kilogram of carbon-12*.
Luminous intensity	I_v	candela	cd	The candela is the luminous intensity in a given direction of a source emitting monochromatic radiation with a frequency of 540×10^{12} hertz and whose energy intensity in that direction is 1/683 watt per steradian.

* When the mole is used, the elementary entities must be specified and may be atoms, molecules, ions, electrons, other particles or specified groups of such particles.

(1) The definitions of the units used in the International System are given in the booklet 'Le Système International d'Unités (SI)', published by the Bureau International des Poids et Mesures, Pavillon de Breteuil, F-92310 Sèvres.

2.1.6. Gas detector tubes.. 17

2.1. APPARATUS

01/2008:20101

2.1.1. DROPPERS

The term ‘drops’ means standard drops delivered from a standard dropper as described below.

Standard droppers (Figure 2.1.1-1) are constructed of practically colourless glass. The lower extremity has a circular orifice in a flat surface at right angles to the axis.

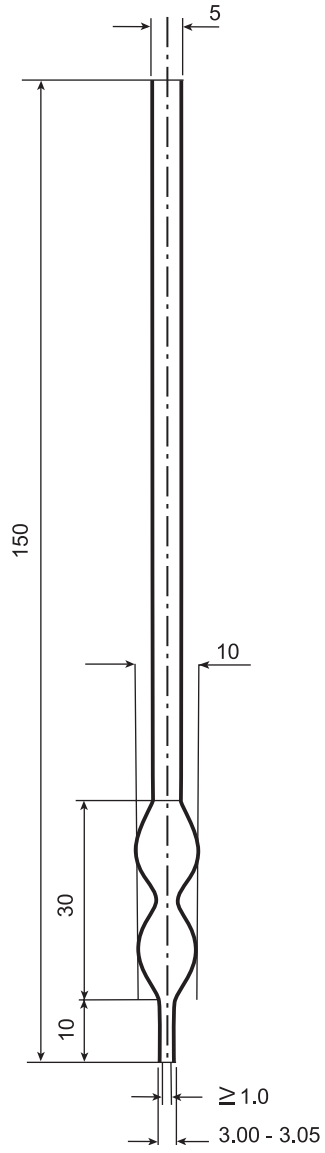

Figure 2.1.1.-1. – *Standard dropper*
Dimensions in millimetres

Other droppers may be used provided they comply with the following test.

20 drops of *water R* at 20 ± 1 °C flowing freely from the dropper held in the vertical position at a constant rate of 1 drop per second weighs 1000 ± 50 mg.

The dropper must be carefully cleaned before use. Carry out 3 determinations on any given dropper. No result may deviate by more than 5 per cent from the mean of the 3 determinations.

01/2008:20102

2.1.2. COMPARATIVE TABLE OF POROSITY OF SINTERED-GLASS FILTERS(1)

Table 2.1.2.-1

Porosity number (Ph. Eur.)(2)	Maximum diameter of pores in micrometres	Germany	France	United Kingdom

Special Uses

Diameters in micrometres

< 2.5	Bacteriological filtration
4 - 10	Ultra-fine filtration, separation of micro-organisms of large diameter
10 - 40	Analytical filtration, very fine filtration of mercury, very fine dispersion of gases
40 - 100	Fine filtration, filtration of mercury, fine dispersion of gases
100 - 160	Filtration of coarse materials, dispersion and washing of gases, support for other filter materials
160 - 500	Filtration of very coarse materials, dispersion and washing of gases.

01/2008:20103

2.1.3. ULTRAVIOLET RAY LAMPS FOR ANALYTICAL PURPOSES

Mercury vapour in quartz lamps is used as the source of ultraviolet light. A suitable filter may be fitted to eliminate the visible part of the spectrum emitted by the lamp. When the Pharmacopoeia prescribes in a test the use of ultraviolet light of wavelength 254 nm or 365 nm, an instrument consisting of a mercury vapour lamp and a filter which gives an emission band with maximum intensity at about 254 nm or 365 nm is used. The lamp used should be capable of revealing without doubt a standard spot of sodium salicylate with a diameter of about 5 mm on a support of *silica gel G R*, the spot being examined while in a position normal to the radiation.

(1) The given limits are only approximate.
(2) The European Pharmacopoeia has adopted the system proposed by the International Organisation for Standardisation (ISO).

For this purpose apply 5 µl of a 0.4 g/l solution of *sodium salicylate R* in *alcohol R*[3] for lamps of maximum output at 254 nm and 5 µl of a 2 g/l solution in *alcohol R*[3] for lamps of maximum output at 365 nm. The distance between the lamp and the chromatographic plate under examination used in a pharmacopoeial test should never exceed the distance used to carry out the above test.

01/2008:20104

2.1.4. SIEVES

Sieves are constructed of suitable materials with square meshes. For purposes other than analytical procedures, sieves with circular meshes may be used, the internal diameters of which are 1.25 times the aperture of the square mesh of the corresponding sieve size. There must be no reaction between the material of the sieve and the substance being sifted. Degree of comminution is prescribed in the monograph using the sieve number, which is the size of the mesh in micrometres, given in parenthesis after the name of the substance (Table 2.1.4.-1).

Maximum tolerance[4] for an aperture (+ *X*): no aperture size shall exceed the nominal size by more than *X*, where:

$$X = \frac{2\left(w^{0.75}\right)}{3} + 4\left(w^{0.25}\right)$$

w = width of aperture.

Tolerance for mean aperture (± *Y*): the average aperture size shall not depart from the nominal size by more than ± *Y*, where:

$$Y = \frac{w^{0.98}}{27} + 1.6$$

Intermediary tolerance (+ *Z*): not more than 6 per cent of the total number of apertures shall have sizes between "nominal + *X*" and "nominal + *Z*", where:

$$Z = \frac{X + Y}{2}$$

Wire diameter *d*: the wire diameters given in Table 2.1.4.-1 apply to woven metal wire cloth mounted in a frame. The nominal sizes of the wire diameters may depart from these values within the limits d_{max} and d_{min}. The limits define a permissible range of choice ± 15 per cent of the recommended nominal dimensions. The wires in a test sieve shall be of a similar diameter in warp and weft directions.

Table 2.1.4.-1 (*values in micrometers*)

Sieve numbers (Nominal dimensions of apertures)	Tolerances for apertures			Wire diameters		
	Maximum tolerance for an aperture	Tolerance for mean aperture	Intermediary tolerance	Recommended nominal dimensions	Admissible limits	
	+ *X*	± *Y*	+ *Z*	*d*	d_{max}	d_{min}
11 200	770	350	560	2500	2900	2100

38	–	–	–	30	35	24

(3) The *alcohol R* used must be free from fluorescence.
(4) See the International Standard ISO 3310/1 (1975).

01/2008:20105

2.1.5. TUBES FOR COMPARATIVE TESTS

Tubes used for comparative tests are matched tubes of colourless glass with a uniform internal diameter. The base is transparent and flat.

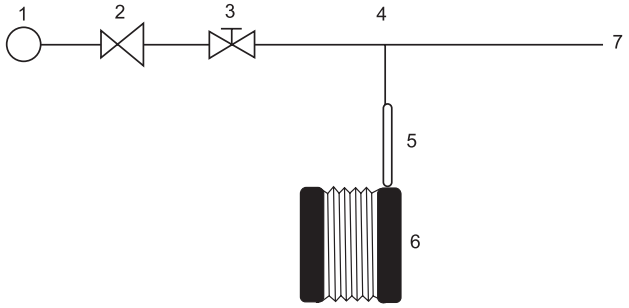
A column of the liquid is examined down the vertical axis of the tube against a white background, or if necessary, against a black background. The examination is carried out in diffused light.

It is assumed that tubes with an internal diameter of 16 mm will be used. Tubes with a larger internal diameter may be used instead but the volume of liquid examined must then be increased so that the depth of liquid in the tubes is not less than where the prescribed volume of liquid and tubes 16 mm in internal diameter are used.

01/2008:20106

2.1.6. GAS DETECTOR TUBES

Gas detector tubes are cylindrical, sealed tubes consisting of an inert transparent material and are constructed to allow the passage of gas. They contain reagents adsorbed onto inert substrates that are suitable for the visualisation of the substance to be detected and, if necessary, they also contain preliminary layers and/or adsorbent filters to eliminate substances that interfere with the substance to be detected. The layer of indicator contains either a single reagent for the detection of a given impurity or several reagents for the detection of several substances (monolayer tube or multilayer tube).



The test is carried out by passing the required volume of the gas to be examined through the indicator tube. The length of the coloured layer or the intensity of a colour change on a graduated scale gives an indication of the impurities present.

The calibration of the detector tubes is verified according to the manufacturer's instructions.

Operating conditions. Examine according to the manufacturer's instructions or proceed as follows:

The gas supply is connected to a suitable pressure regulator and needle valve. Connect the flexible tubing fitted with a Y-piece to the valve and adjust the flow of gas to be examined to purge the tubing in order to obtain an appropriate flow (Figure 2.1.6.-1). Prepare the indicator tube and fit to the metering pump, following the manufacturer's instructions. Connect the open end of the indicator tube to the short leg of the tubing and operate the pump by the appropriate number of strokes to pass a suitable volume of gas to be examined through the tube. Read the value corresponding to the length of the coloured layer or the intensity of the colour on the graduated scale. If a negative result is achieved, indicator tubes can be verified with a calibration gas containing the appropriate impurity.

In view of the wide variety of available compressor oils, it is necessary to verify the reactivity of the oil detector tubes for the oil used. Information on the reactivity for various oils is given in the leaflet supplied with the tube. If the oil used is not cited in the leaflet, the tube manufacturer must verify the reactivity and if necessary provide a tube specific for this oil.

1. Gas supply
2. Pressure regulator
3. Needle valve
4. "Y"-piece
5. Indicator tube
6. Indicator tube pump
7. End open to atmosphere

Figure 2.1.6.-1. – *Apparatus for gas detector tubes*

Carbon dioxide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for hydrazine and crystal violet indicators. The minimum value indicated is 100 ppm with a relative standard deviation of at most ± 15 per cent.

Sulphur dioxide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for the iodine and starch indicator. The minimum value indicated is 0.5 ppm with a relative standard deviation of at most ± 15 per cent.

Oil detector tube. Sealed glass tube containing adsorbent filters and suitable supports for the sulphuric acid indicator. The minimum value indicated is 0.1 mg/m^3 with a relative standard deviation of at most ± 30 per cent.

Nitrogen monoxide and nitrogen dioxide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for an oxidising layer (Cr(VI) salt) and the diphenylbenzidine indicator. The minimum value indicated is 0.5 ppm with a relative standard deviation of at most ± 15 per cent.

Carbon monoxide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for di-iodine pentoxide, selenium dioxide and fuming sulphuric acid indicators. The minimum value indicated is 5 ppm or less, with a relative standard deviation of at most ± 15 per cent.

Hydrogen sulphide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for an appropriate lead salt indicator. The minimum value indicated is 1 ppm or less, with a relative standard deviation of at most ± 10 per cent.

Water vapour detector tube. Sealed glass tube containing adsorbent filters and suitable supports for the magnesium perchlorate indicator. The minimum value indicated is 67 ppm or less, with a relative standard deviation of at most ± 20 per cent.

2.2. PHYSICAL AND PHYSICOCHEMICAL METHODS

01/2008:20201

2.2.1. CLARITY AND DEGREE OF OPALESCENCE OF LIQUIDS

VISUAL METHOD

Using identical test-tubes of colourless, transparent, neutral glass with a flat base and an internal diameter of 15-25 mm, compare the liquid to be examined with a reference suspension freshly prepared as described below, the depth of the layer being 40 mm. Compare the solutions in diffused daylight 5 min after preparation of the reference suspension, viewing vertically against a black background. The diffusion of light must be such that reference suspension I can readily be distinguished from *water R*, and that reference suspension II can readily be distinguished from reference suspension I.

A liquid is considered *clear* if its clarity is the same as that of *water R* or of the solvent used when examined under the conditions described above, or if its opalescence is not more pronounced than that of reference suspension I.

Hydrazine sulphate solution. Dissolve 1.0 g of *hydrazine sulphate R* in *water R* and dilute to 100.0 ml with the same solvent. Allow to stand for 4-6 h.

Hexamethylenetetramine solution. In a 100 ml ground-glass-stoppered flask, dissolve 2.5 g of *hexamethylenetetramine R* in 25.0 ml of *water R*.

Primary opalescent suspension (formazin suspension). To the hexamethylenetetramine solution in the flask add 25.0 ml of the hydrazine sulphate solution. Mix and allow to stand for 24 h. This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.

Standard of opalescence. Dilute 15.0 ml of the primary opalescent suspension to 1000.0 ml with *water R*. This suspension is freshly prepared and may be stored for up to 24 h.

Reference suspensions. Prepare the reference suspensions according to Table 2.2.1.-1. Mix and shake before use.

Table 2.2.1.-1

	I	II	III	IV
Standard of opalescence	5.0 ml	10.0 ml	30.0 ml	50.0 ml
Water R	95.0 ml	90.0 ml	70.0 ml	50.0 ml

Turbidity standard. The formazin suspension prepared by mixing equal volumes of the hydrazine sulphate solution and the hexamethylenetetramine solution is defined as a 4000 NTU (nephelometric turbidity units) primary reference standard. Reference suspensions I, II, III and IV have values of 3 NTU, 6 NTU, 18 NTU and 30 NTU respectively. Stabilised formazin suspensions that can be used to prepare stable, diluted turbidity standards are available commercially and may be used after comparison with the standards prepared as described.

Formazin has several desirable characteristics that make it an excellent turbidity standard. It can be reproducibly prepared from assayed raw materials. The physical characteristics make it a desirable light-scatter calibration standard. The formazin polymer consists of chains of different lengths, which fold into random configurations. This results in a wide assay of particle shapes and sizes, which analytically fits the possibility of different particle sizes and shapes that are found in the real samples. Due to formazin's reproducibility, scattering characteristics and traceability, instrument calibration algorithms and performance criteria are mostly based on this standard.

INSTRUMENTAL METHODS

INTRODUCTION

The degree of opalescence may also be determined by instrumental measurement of the light absorbed or scattered on account of submicroscopic optical density inhomogeneities of opalescent solutions and suspensions. 2 such techniques are nephelometry and turbidimetry. For turbidity measurement of coloured samples, ratio turbidimetry and nephelometry with ratio selection are used.

The light scattering effect of suspended particles can be measured by observation of either the transmitted light (turbidimetry) or the scattered light (nephelometry). Ratio turbidimetry combines the principles of both nephelometry and turbidimetry. Turbidimetry and nephelometry are useful for the measurement of slightly opalescent suspensions. Reference suspensions produced under well-defined conditions must be used. For quantitative measurements, the construction of calibration curves is essential, since the relationship between the optical properties of the suspension and the concentration of the dispersed phase is at best semi-empirical.

The determination of opalescence of coloured liquids is done with ratio turbidimeters or nephelometers with ratio selection, since colour provides a negative interference, attenuating both incident and scattered light and lowering the turbidity value. The effect is so great for even moderately coloured samples that conventional nephelometers cannot be used.

The instrumental assessment of clarity and opalescence provides a more discriminatory test that does not depend on the visual acuity of the analyst. Numerical results are more useful for quality monitoring and process control, especially in stability studies. For example, previous numerical data on stability can be projected to determine whether a given batch of dosage formulation or active pharmaceutical ingredient will exceed shelf-life limits prior to the expiry date.

NEPHELOMETRY

When a suspension is viewed at right angles to the direction of the incident light, the system appears opalescent due to the reflection of light from the particles of the suspension (Tyndall effect). A certain portion of the light beam entering a turbid liquid is transmitted, another portion is absorbed and the remaining portion is scattered by the suspended particles. If measurement is made at 90° to the light beam, the light scattered by the suspended particles can be used for the determination of their concentration, provided the number and size of particles influencing the scattering remain constant. The reference suspension must maintain a constant degree of turbidity and the sample and reference suspensions must be prepared under identical conditions. The Tyndall effect depends upon both the number of particles and their size. Nephelometric measurements are more reliable in low turbidity ranges, where there is a linear relationship between nephelometric turbidity unit (NTU) values and relative detector signals. As the degree of turbidity increases, not all the particles are exposed to the incident light and the scattered radiation of other particles is hindered on its way to the detector. The maximum nephelometric values at which reliable measurements can be

made lie in the range of 1750-2000 NTU. Linearity must be demonstrated by constructing a calibration curve using at least 4 concentrations.

TURBIDIMETRY

The optical property expressed as turbidity is the interaction between light and suspended particles in liquid. This is an expression of the optical property that causes light to be scattered and absorbed rather than transmitted in a straight line through the sample. The quantity of solid material in suspension can be determined by the measurement of the transmitted light. A linear relationship between turbidity and concentration is obtained when the particle sizes are uniform and homogeneous in the suspension. This is true only in very dilute suspensions containing small particles. Linearity between turbidity and concentration must be established by constructing a calibration curve using at least 4 concentrations.

RATIO TURBIDIMETRY

In ratio turbidimetry the relationship of the transmission measurement to the 90° scattered light measurement is determined. This procedure compensates for the light that is diminished by the colour of the sample. The influence of the colour of the sample may also be eliminated by using an infrared light-emitting diode (IR LED) at 860 nm as the light source of the instrument. The instrument's photodiode detectors receive and measure scattered light at a 90° angle from the sample as well as measuring the forward scatter (light reflected) in front of the sample along with the measurement of light transmitted directly through the sample. The measuring results are given in NTU(ratio) and are obtained by calculating the ratio of the 90° angle scattered light measured to the sum of the components of forward scattered and transmitted light values. In ratio turbidimetry the influence of stray light becomes negligible. Nephelometers are used for measurements of the degree of opalescence of colourless liquids.

Measurements of reference suspensions I-IV with a ratio turbidimeter show a linear relationship between the concentrations and measured NTU values. Reference suspensions I-IV (Ph. Eur.) may be used as calibrators for the instrument.

Table 2.2.1.-2

Formazin suspensions	Opalescent values (NTU)
Reference suspension I	3
Reference suspension II	6
Reference suspension III	18
Reference suspension IV	30
Standard of opalescence	60
Primary opalescent suspension	4000

INSTRUMENTAL DETERMINATION OF OPALESCENCE

Requirements in monographs are expressed in terms of the visual examination method with the defined reference suspensions. Instrumental methods may also be used for determining compliance with monograph requirements once the suitability of the instrument as described below has been established and calibration with reference suspensions I-IV and with *water R* or the solvent used has been performed.

Apparatus. Ratio turbidimeters or nephelometers with selectable ratio application use as light source a tungsten lamp with spectral sensitivity at about 550 nm operating at a filament colour temperature of 2700 K, or IR LED having an emission maximum at 860 nm with a 60 nm spectral bandwidth. Other suitable light sources may also be used. Silicon photodiodes and photomultipliers are commonly used as detectors and record changes in light scattered or transmitted by the sample. The light scattered at 90 ± 2.5° is detected by the primary detector. Other detectors are those to detect back and forward scatter as well as transmitted light. The instruments used are calibrated against standards of known turbidity and are capable of automatic determination of turbidity. The test results expressed in NTU units are obtained directly from the instrument and compared to the specifications in the individual monographs.

Instruments complying with the following specifications are suitable.

- *Measuring units*: NTU. NTU is based on the turbidity of a primary reference standard of formazin. FTU (Formazin Turbidity Units) or FNU (Formazin Nephelometry Units) are also used, and are equivalent to NTU in low regions (up to 40 NTU). These units are used in all 3 instrumental methods (nephelometry, turbidimetry and ratio turbidimetry).
- *Measuring range*: 0.01-1100 NTU.
- *Resolution*: 0.01 NTU within the range of 0-10 NTU, 0.1 NTU within the range of 10-100 NTU, and 1 NTU for the range > 100 NTU. The instrument is calibrated and controlled with reference standards of formazin.
- *Accuracy*: 0-10 NTU: ± (2 per cent of reading + 0.01) NTU. 10-1000 NTU: ± 5 per cent.
- *Repeatability*: 0-10 NTU: ± 0.01 NTU. 10-1000 NTU: ± 2 per cent of the measured value.
- *Calibration*: with 4 reference suspensions of formazin in the range of interest. Reference suspensions described in this chapter or suitable reference standards calibrated against the primary reference suspensions may be used.
- *Stray light*: this is a significant source of error in low level turbidimetric measurement; stray light reaches the detector of an optical system, but does not come from the sample; < 0.15 NTU for the range 0-10 NTU, < 0.5 NTU for the range 10-1000 NTU.

Instruments complying with the above characteristics and verified using the reference suspensions described under Visual method may be used instead of visual examination for determination of compliance with monograph requirements.

Instruments with range or resolution, accuracy and repeatability capabilities other than those mentioned above may be used provided they are sufficiently validated and are capable for the intended use. The test methodology for the specific substance/product to be analysed must also be validated to demonstrate its analytical capability. The instrument and methodology should be consistent with the attributes of the product to be tested.

01/2008:20202

2.2.2. DEGREE OF COLORATION OF LIQUIDS

The examination of the degree of coloration of liquids in the range brown-yellow-red is carried out by one of the 2 methods below, as prescribed in the monograph.

A solution is *colourless* if it has the appearance of *water R* or the solvent or is not more intensely coloured than reference solution B_9.

METHOD I

Using identical tubes of colourless, transparent, neutral glass of 12 mm external diameter, compare 2.0 ml of the liquid to be examined with 2.0 ml of *water R* or of the solvent or of the reference solution (see Tables of reference

solutions) prescribed in the monograph. Compare the colours in diffused daylight, viewing horizontally against a white background.

METHOD II

Using identical tubes of colourless, transparent, neutral glass with a flat base and an internal diameter of 15 mm to 25 mm, compare the liquid to be examined with *water R* or the solvent or the reference solution (see Tables of reference solutions) prescribed in the monograph, the depth of the layer being 40 mm. Compare the colours in diffused daylight, viewing vertically against a white background.

REAGENTS

Primary solutions

Yellow solution. Dissolve 46 g of *ferric chloride R* in about 900 ml of a mixture of 25 ml of *hydrochloric acid R* and 975 ml of *water R* and dilute to 1000.0 ml with the same mixture. Titrate and adjust the solution to contain 45.0 mg of $FeCl_3,6H_2O$ per millilitre by adding the same acidic mixture. Protect the solution from light.

Titration. Place in a 250 ml conical flask fitted with a ground-glass stopper, 10.0 ml of the solution, 15 ml of *water R*, 5 ml of *hydrochloric acid R* and 4 g of *potassium iodide R*, close the flask, allow to stand in the dark for 15 min and add 100 ml of *water R*. Titrate the liberated iodine with *0.1 M sodium thiosulphate*, using 0.5 ml of *starch solution R*, added towards the end of the titration, as indicator.

1 ml of *0.1 M sodium thiosulphate* is equivalent to 27.03 mg of $FeCl_3,6H_2O$.

Red solution. Dissolve 60 g of *cobalt chloride R* in about 900 ml of a mixture of 25 ml of *hydrochloric acid R* and 975 ml of *water R* and dilute to 1000.0 ml with the same mixture. Titrate and adjust the solution to contain 59.5 mg of $CoCl_2,6H_2O$ per millilitre by adding the same acidic mixture.

Titration. Place in a 250 ml conical flask fitted with a ground-glass stopper, 5.0 ml of the solution, 5 ml of *dilute hydrogen peroxide solution R* and 10 ml of a 300 g/l solution of *sodium hydroxide R*. Boil gently for 10 min, allow to cool and add 60 ml of *dilute sulphuric acid R* and 2 g of *potassium iodide R*. Close the flask and dissolve the precipitate by shaking gently. Titrate the liberated iodine with *0.1 M sodium thiosulphate*, using 0.5 ml of *starch solution R*, added towards the end of the titration, as indicator. The end-point is reached when the solution turns pink.

1 ml of *0.1 M sodium thiosulphate* is equivalent to 23.79 mg of $CoCl_2,6H_2O$.

Blue primary solution. Dissolve 63 g of *copper sulphate R* in about 900 ml of a mixture of 25 ml of *hydrochloric acid R* and 975 ml of *water R* and dilute to 1000.0 ml with the same mixture. Titrate and adjust the solution to contain 62.4 mg of $CuSO_4,5H_2O$ per millilitre by adding the same acidic mixture.

Titration. Place in a 250 ml conical flask fitted with a ground-glass stopper, 10.0 ml of the solution, 50 ml of *water R*, 12 ml of *dilute acetic acid R* and 3 g of *potassium iodide R*. Titrate the liberated iodine with *0.1 M sodium thiosulphate*, using 0.5 ml of *starch solution R*, added towards the end of the titration, as indicator. The end-point is reached when the solution shows a slight pale brown colour.

1 ml of *0.1 M sodium thiosulphate* is equivalent to 24.97 mg of $CuSO_4,5H_2O$.

Standard solutions

Using the 3 primary solutions, prepare the 5 standard solutions as follows:

Table 2.2.2.-1

Standard solution	Volume in millilitres			
	Yellow solution	Red solution	Blue solution	Hydrochloric acid (10 g/l HCl)
B (brown)	3.0	3.0	2.4	1.6
BY (brownish-yellow)	2.4	1.0	0.4	6.2
Y (yellow)	2.4	0.6	0.0	7.0
GY (greenish-yellow)	9.6	0.2	0.2	0.0
R (red)	1.0	2.0	0.0	7.0

Reference solutions for Methods I and II

Using the 5 standard solutions, prepare the following reference solutions.

Table 2.2.2.-2. - *Reference solutions B*

Reference solution	Volumes in millilitres

R_4	37.5	62.5
R_5	25.0	75.0
R_6	12.5	87.5
R_7	5.0	95.0

Storage

For Method I, the reference solutions may be stored in sealed tubes of colourless, transparent, neutral glass of 12 mm external diameter, protected from light.

For Method II, prepare the reference solutions immediately before use from the standard solutions.

01/2008:20203

2.2.3. POTENTIOMETRIC DETERMINATION OF pH

The pH is a number which represents conventionally the hydrogen ion concentration of an aqueous solution. For practical purposes, its definition is an experimental one. The pH of a solution to be examined is related to that of a reference solution (pH_s) by the following equation:

$$\mathrm{pH} = \mathrm{pH_s} - \frac{E - E_s}{k}$$

in which E is the potential, expressed in volts, of the cell containing the solution to be examined and E_s is the potential, expressed in volts, of the cell containing the solution of known pH (pH_s), k is the change in potential per unit change in pH expressed in volts, and calculated from the Nernst equation.

Table 2.2.3.-1. – *Values of k at different temperatures*

Temperature (°C)	*k* (V)
15	0.0572
20	0.0582
25	0.0592
30	0.0601
35	0.0611

The potentiometric determination of pH is made by measuring the potential difference between 2 appropriate electrodes immersed in the solution to be examined: 1 of these electrodes is sensitive to hydrogen ions (usually a glass electrode) and the other is the reference electrode (for example, a saturated calomel electrode).

Apparatus. The measuring apparatus is a voltmeter with an input resistance at least 100 times that of the electrodes used. It is normally graduated in pH units and has a sensitivity such that discrimination of at least 0.05 pH unit or at least 0.003 V may be achieved.

Method. Unless otherwise prescribed in the monograph, all measurements are made at the same temperature (20-25 °C). Table 2.2.3.-2 shows the variation of pH with respect to temperature of a number of reference buffer solutions used for calibration. For the temperature correction, when necessary, follow the manufacturer's instructions. The apparatus is calibrated with the buffer solution of potassium hydrogen phthalate (primary standard) and 1 other buffer solution of different pH (preferably one shown in Table 2.2.3.-2). The pH of a third buffer solution of intermediate pH read off on the scale must not differ by more than 0.05 pH unit from the value corresponding to this solution. Immerse the electrodes in the solution to be examined and take the reading in the same conditions as for the buffer solutions.

When the apparatus is in frequent use, checks must be carried out regularly. If not, such checks should be carried out before each measurement.

All solutions to be examined and the reference buffer solutions must be prepared using *carbon dioxide-free water R*.

PREPARATION OF REFERENCE BUFFER SOLUTIONS

Potassium tetraoxalate 0.05 M. Dissolve 12.61 g of $C_4H_3KO_8,2H_2O$ in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Potassium hydrogen tartrate, saturated at 25 °C. Shake an excess of $C_4H_5KO_6$ vigorously with *carbon dioxide-free water R* at 25 °C. Filter or decant. Prepare immediately before use.

Potassium dihydrogen citrate 0.05 M. Dissolve 11.41 g of $C_6H_7KO_7$ in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent. Prepare immediately before use.

Potassium hydrogen phthalate 0.05 M. Dissolve 10.13 g of $C_8H_5KO_4$, previously dried for 1 h at 110 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Potassium dihydrogen phosphate 0.025 M + disodium hydrogen phosphate 0.025 M. Dissolve 3.39 g of KH_2PO_4 and 3.53 g of Na_2HPO_4, both previously dried for 2 h at 120 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Potassium dihydrogen phosphate 0.0087 M + disodium hydrogen phosphate 0.0303 M. Dissolve 1.18 g of KH_2PO_4 and 4.30 g of Na_2HPO_4, both previously dried for 2 h at 120 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Disodium tetraborate 0.01 M. Dissolve 3.80 g of $Na_2B_4O_7,10H_2O$ in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent. Store protected from atmospheric carbon dioxide.

Table 2.2.3.-2. – *pH of reference buffer solutions at various temperatures*

Temperature (°C)	Potassium tetraoxalate 0.05 M	Potassium hydrogen tartrate saturated at 25 °C	Potassium dihydrogen citrate 0.05 M	Potassium hydrogen phthalate 0.05 M	Potassium dihydrogen phosphate 0.025 M + disodium hydrogen phosphate 0.025 M	Potassium dihydrogen phosphate 0.0087 M + disodium hydrogen phosphate 0.0303 M	Disodium tetraborate 0.01 M	Sodium carbonate 0.025 M + sodium bicarbonate 0.025 M	Calcium hydroxide, saturated at 25°C
	$C_4H_3KO_8,2H_2O$	$C_4H_5KO_6$	$C_6H_7KO_7$	$C_8H_5KO_4$	KH_2PO_4+ Na_2HPO_4	KH_2PO_4+ Na_2HPO_4	$Na_2B_4O_7$, $10H_2O$	Na_2CO_3+ $NaHCO_3$	$Ca(OH)_2$

(1) pH variation per degree Celsius.

Sodium carbonate 0.025 M + sodium hydrogen carbonate 0.025 M. Dissolve 2.64 g of Na_2CO_3 and 2.09 g of $NaHCO_3$ in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent. Store protected from atmospheric carbon dioxide.

Calcium hydroxide, saturated at 25 °C. Shake an excess of *calcium hydroxide R* with *carbon dioxide-free water R* and decant at 25 °C. Store protected from atmospheric carbon dioxide.

STORAGE

Store buffer solutions in suitable chemically resistant, tight containers, such as type I glass bottles or plastic containers suitable for aqueous solutions.

01/2008:20204

2.2.4. RELATIONSHIP BETWEEN REACTION OF SOLUTION, APPROXIMATE pH AND COLOUR OF CERTAIN INDICATORS

To 10 ml of the solution to be examined, add 0.1 ml of the indicator solution, unless otherwise prescribed in Table 2.2.4.-1.

Table 2.2.4.-1

Reaction	pH	Indicator	Colour
Alkaline	> 8	*Litmus paper red R*	Blue
		Thymol blue solution R (0.05 ml)	Grey or violet-blue
Slightly alkaline	8.0 – 10.0	*Phenolphthalein solution R* (0.05 ml)	Colourless or pink
		Thymol blue solution R (0.05 ml)	Grey
Strongly alkaline	> 10	*Phenolphthalein paper R*	Red
		Thymol blue solution R (0.05 ml)	Violet-blue
Neutral	6.0 – 8.0	*Methyl red solution R*	Yellow
		Phenol red solution R (0.05 ml)	
Neutral to methyl red	4.5 – 6.0	*Methyl red solution R*	Orange-red
Neutral to phenolphtalein	< 8.0	*Phenolphthalein solution R* (0.05 ml)	Colourless; pink or red after adding 0.05 ml of 0.1 M base
Acid	< 6	*Methyl red solution R*	Orange or red
		Bromothymol blue solution R1	Yellow
Faintly acid	4.0 – 6.0	*Methyl red solution R*	Orange
		Bromocresol green solution R	Green or blue
Strongly acid	< 4	*Congo red paper R*	Green or blue

01/2008:20205

2.2.5. RELATIVE DENSITY

The relative density $d_{t_2}^{t_1}$ of a substance is the ratio of the mass of a certain volume of a substance at temperature t_1 to the mass of an equal volume of water at temperature t_2. Unless otherwise indicated, the relative density d_{20}^{20} is used. Relative density is also commonly expressed as d_4^{20}. Density ρ_{20}, defined as the mass of a unit volume of the substance at 20 °C may also be used, expressed in kilograms per cubic metre or grams per cubic centimetre (1 kg·m^{-3} = 10^{-3} g·cm^{-3}). These quantities are related by the following equations where density is expressed in grams per cubic centimetre:

$$\rho_{20} = 0.998203 \times d_{20}^{20} \quad \text{or} \quad d_{20}^{20} = 1.00180 \times \rho_{20}$$

$$\rho_{20} = 0.999972 \times d_4^{20} \quad \text{or} \quad d_4^{20} = 1.00003 \times \rho_{20}$$

$$d_4^{20} = 0.998230 \times d_{20}^{20}$$

Relative density or density are measured with the precision to the number of decimals prescribed in the monograph using a density bottle (solids or liquids), a hydrostatic balance (solids), a hydrometer (liquids) or a digital density meter with an oscillating transducer (liquids and gases).

When the determination is made by weighing, the buoyancy of air is disregarded, which may introduce an error of 1 unit in the 3rd decimal place. When using a density meter, the buoyancy of air has no influence.

Oscillating transducer density meter. The apparatus consists of:

- a U-shaped tube, usually of borosilicate glass, which contains the liquid to be examined;
- a magneto-electrical or piezo-electrical excitation system that causes the tube to oscillate as a cantilever oscillator at a characteristic frequency depending on the density of the liquid to be examined;
- a means of measuring the oscillation period (*T*), which may be converted by the apparatus to give a direct reading of density, or used to calculate density using the constants *A* and *B* described below.

The resonant frequency (*f*) is a function of the spring constant (*c*) and the mass (*m*) of the system:

$$f^2 = \frac{1}{T^2} = \frac{c}{m} \times \frac{1}{4\pi^2}$$

Hence:

$$T^2 = \left(\frac{M}{c} + \frac{\rho \times V}{c} \right) \times 4\pi^2$$

M = mass of the tube,

V = inner volume of the tube.

Introduction of 2 constants $A = c/\left(4\pi^2 \times V\right)$ and $B = M/V$, leads to the classical equation for the oscillating transducer:

$$\rho = A \times T^2 - B$$

The constants *A* and *B* are determined by operating the instrument with the U-tube filled with 2 different samples of known density, for example, degassed *water R* and air. Control measurements are made daily using degassed *water R*. The results displayed for the control measurement using degassed *water R* shall not deviate from the reference value (ρ_{20} = 0.998203 g·cm^{-3}, d_{20}^{20} = 1.000000) by more than its specified error. For example, an instrument specified to ± 0.0001 g·cm^{-3} shall display 0.9982 ± 0.0001 g·cm^{-3} in order to be suitable for further measurement. Otherwise a re-adjustment is necessary. Calibration with certified reference materials is carried out regularly. Measurements are made using the same procedure as for calibration. The liquid to be examined is equilibrated in a thermostat at 20 °C before introduction into the tube, if necessary, to avoid the formation of bubbles and to reduce the time required for measurement.

Factors affecting accuracy include:

- temperature uniformity throughout the tube,
- non-linearity over a range of density,
- parasitic resonant effects,
- viscosity, whereby solutions with a higher viscosity than the calibrant have a density that is apparently higher than the true value.

The effects of non-linearity and viscosity may be avoided by using calibrants that have density and viscosity close to those of the liquid to be examined (± 5 per cent for density, ± 50 per cent for viscosity). The density meter may have functions for automatic viscosity correction and for correction of errors arising from temperature changes and non-linearity.

Precision is a function of the repeatability and stability of the oscillator frequency, which is dependent on the stability of the volume, mass and spring constant of the cell.

Density meters are able to achieve measurements with an error of the order of 1 × 10^{-3} g·cm^{-3} to 1 × 10^{-5} g·cm^{-3} and a repeatability of 1 × 10^{-4} g·cm^{-3} to 1 × 10^{-6} g·cm^{-3}.

01/2008:20206

2.2.6. REFRACTIVE INDEX

The refractive index of a medium with reference to air is equal to the ratio of the sine of the angle of incidence of a beam of light in air to the sine of the angle of refraction of the refracted beam in the given medium.

Unless otherwise prescribed, the refractive index is measured at 20 ± 0.5 °C, with reference to the wavelength of the D-line of sodium (λ = 589.3 nm); the symbol is then n_D^{20}.

Refractometers normally determine the critical angle. In such apparatus the essential part is a prism of known refractive index in contact with the liquid to be examined.

Calibrate the apparatus using certified reference materials.

When white light is used, the refractometer is provided with a compensating system. The apparatus gives readings accurate to at least the third decimal place and is provided with a means of operation at the temperature prescribed. The thermometer is graduated at intervals of 0.5 °C or less.

01/2008:20207

2.2.7. OPTICAL ROTATION

Optical rotation is the property displayed by chiral substances of rotating the plane of polarisation of polarised light.

Optical rotation is considered to be positive (+) for dextrorotatory substances (i.e. those that rotate the plane of polarisation in a clockwise direction) and negative (–) for laevorotatory substances.

The specific optical rotation $[\alpha_m]_\lambda^t$ is the rotation, expressed in radians (rad), measured at the temperature *t* and at the wavelength λ given by a 1 m thickness of liquid or a solution containing 1 kg/m^3 of optically active substance. For practical reasons the specific optical rotation $[\alpha_m]_\lambda^t$ is normally expressed in milliradians metre squared per kilogram (mrad·m^2·kg^{-1}).

The Pharmacopoeia adopts the following conventional definitions.

The *angle of optical rotation* of a neat liquid is the angle of rotation α, expressed in degrees (°), of the plane of polarisation at the wavelength of the D-line of sodium (λ = 589.3 nm) measured at 20 °C using a layer of 1 dm; for a solution, the method of preparation is prescribed in the monograph.

The *specific optical rotation* $[\alpha]_D^{20}$ of a liquid is the angle of rotation α, expressed in degrees (°), of the plane of polarisation at the wavelength of the D-line of sodium (λ = 589.3 nm) measured at 20 °C in the liquid substance to be examined, calculated with reference to a layer of 1 dm and divided by the density expressed in grams per cubic centimetre.

The *specific optical rotation* $[\alpha]_D^{20}$ of a substance in solution is the angle of rotation α, expressed in degrees (°), of the plane of polarisation at the wavelength of the D-line of sodium (λ = 589.3 nm) measured at 20 °C in a solution of the substance to be examined and calculated with reference

to a layer of 1 dm containing 1 g/ml of the substance. The specific optical rotation of a substance in solution is always expressed with reference to a given solvent and concentration.

In the conventional system adopted by the Pharmacopoeia the specific optical rotation is expressed by its value without units; the actual units, degree millilitres per decimetre gram [(°)·ml·dm^{-1}·g^{-1}] are understood.

The conversion factor from the International System to the Pharmacopoeia system is the following:

$$[\alpha_m]_\lambda^t = [\alpha]_\lambda^t \times 0.1745$$

In certain cases specified in the monograph the angle of rotation may be measured at temperatures other than 20 °C and at other wavelengths.

The polarimeter must be capable of giving readings to the nearest 0.01°. The scale is usually checked by means of certified quartz plates. The linearity of the scale may be checked by means of sucrose solutions.

Method. Determine the zero of the polarimeter and the angle of rotation of polarised light at the wavelength of the D-line of sodium (λ = 589.3 nm) at 20 ± 0.5 °C, unless otherwise prescribed. Measurements may be carried out at other temperatures only where the monograph indicates the temperature correction to be made to the measured optical rotation. Determine the zero of the apparatus with the tube closed; for liquids the zero is determined with the tube empty and for solids filled with the prescribed solvent.

Calculate the specific optical rotation using the following formulae.

For neat liquids:

$$[\alpha]_D^{20} = \frac{\alpha}{l \cdot \rho_{20}}$$

For substances in solution:

$$[\alpha]_D^{20} = \frac{1000\alpha}{l \cdot c}$$

where c is the concentration of the solution in grams per litre.

Calculate the content c in grams per litre or the content c' in per cent *m/m* of a dissolved substance using the following formulae:

$$c = \frac{1000\alpha}{l \cdot [\alpha]_D^{20}} \qquad c' = \frac{100\alpha}{l \cdot [\alpha]_D^{20} \cdot \rho_{20}}$$

α = angle of rotation in degrees read at 20 ± 0.5°C;

l = length in decimetres of the polarimeter tube;

ρ_{20} = density at 20 °C in grams per cubic centimetre. For the purposes of the Pharmacopoeia, density is replaced by relative density (*2.2.5*).

01/2008:20208

2.2.8. VISCOSITY

The *dynamic* viscosity or *viscosity coefficient* η is the tangential force per unit surface, known as *shearing stress* τ and expressed in pascals, necessary to move, parallel to the sliding plane, a layer of liquid of 1 square metre at a rate (v) of 1 metre per second relative to a parallel layer at a distance (x) of 1 metre.

The ratio dv/dx is a speed gradient giving the *rate of shear D* expressed in reciprocal seconds (s^{-1}), so that $\eta = \tau/D$.

The unit of dynamic viscosity is the pascal second (Pa·s). The most commonly used submultiple is the millipascal second (mPa·s).

The *kinematic viscosity v*, expressed in square metres per second, is obtained by dividing the dynamic viscosity η by the density ρ expressed in kilograms per cubic metre, of the liquid measured at the same temperature, i.e. $v = \eta/\rho$. The kinematic viscosity is usually expressed in square millimetres per second.

A capillary viscometer may be used for determining the viscosity of Newtonian liquids and a rotating viscometer for determining the viscosity of Newtonian and non-Newtonian liquids. Other viscometers may be used provided that the accuracy and precision is not less than that obtained with the viscometers described below.

01/2008:20209

2.2.9. CAPILLARY VISCOMETER METHOD

The determination of viscosity using a suitable capillary viscometer is carried out at a temperature of 20 ± 0.1 °C, unless otherwise prescribed. The time required for the level of the liquid to drop from one mark to the other is measured with a stop-watch to the nearest one-fifth of a second. The result is valid only if two consecutive readings do not differ by more than 1 per cent. The average of not fewer than three readings gives the flow time of the liquid to be examined.

Calculate the dynamic viscosity η (*2.2.8*) in millipascal seconds using the formula:

$$\eta = k\rho t$$

k = constant of the viscometer, expressed in square millimetres per second squared,

ρ = density of the liquid to be examined expressed in milligrams per cubic millimetre, obtained by multiplying its relative density (d_{20}^{20}) by 0.9982,

t = flow time, in seconds, of the liquid to be examined.

The constant k is determined using a suitable viscometer calibration liquid.

To calculate the kinematic viscosity (mm^2·s^{-1}), use the following formula: $v = kt$.

(1) The European Pharmacopoeia describes the system proposed by the International Organisation for Standardisation (ISO).

The determination may be carried out with an apparatus (Figure 2.2.9.-1) having the specifications described in Table 2.2.9.-1[1]:

Table 2.2.9.-1

Size number	Nominal constant of viscometer	Kinematic viscosity range	Internal diameter of tube *R*	Volume of bulb *C*	Internal diameter of tube *N*
	$mm^2 \cdot s^{-2}$	$mm^2 \cdot s^{-1}$	mm (± 2 %)	ml (± 5 %)	mm
1	0.01	3.5 to 10	0.64	5.6	2.8 to 3.2
1A	0.03	6 to 30	0.84	5.6	2.8 to 3.2
2	0.1	20 to 100	1.15	5.6	2.8 to 3.2
2A	0.3	60 to 300	1.51	5.6	2.8 to 3.2
3	1.0	200 to 1000	2.06	5.6	3.7 to 4.3
3A	3.0	600 to 3000	2.74	5.6	4.6 to 5.4
4	10	2000 to 10 000	3.70	5.6	4.6 to 5.4
4A	30	6000 to 30 000	4.07	5.6	5.6 to 6.4
5	100	20 000 to 100 000	6.76	5.6	6.8 to 7.5

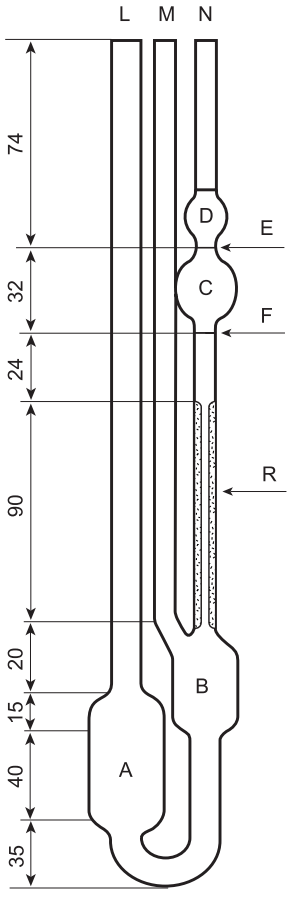

Figure 2.2.9.- 1. – *Suspended level viscometer*
Dimensions in millimetres

The minimum flow time should be 350 s for size no. 1 and 200 s for all other sizes.

Method. Fill the viscometer through tube (*L*) with a sufficient quantity of the liquid to be examined, previously brought to 20 °C unless otherwise prescribed, to fill bulb (*A*) but ensuring that the level of liquid in bulb (*B*) is below the exit to ventilation tube (*M*). Immerse the viscometer in the bath of water at 20 ± 0.1 °C, unless otherwise prescribed, maintain it in the upright position and allow to stand for not less than 30 min to allow the temperature to reach equilibrium. Close tube (*M*) and raise the level of the liquid in tube (*N*) up to a level about 8 mm above mark (*E*). Keep the liquid at this level by closing tube (*N*) and opening tube (*M*). Open tube (*N*) and measure, with a stop-watch to the nearest one-fifth of a second, the time required for the level of the liquid to drop from mark (*E*) to (*F*).

01/2008:20210

2.2.10. VISCOSITY - ROTATING VISCOMETER METHOD

The principle of the method is to measure the force acting on a rotor (torque) when it rotates at a constant angular velocity (rotational speed) in a liquid. Rotating viscometers are used for measuring the viscosity of Newtonian (shear-independent viscosity) or non-Newtonian liquids (shear dependent viscosity or apparent viscosity). Rotating viscometers can be divided in 2 groups, namely absolute and relative viscometers. In absolute viscometers the flow in the measuring geometry is well defined. The measurements result in absolute viscosity values, which can be compared with any other absolute values. In relative viscometers the flow in the measuring geometry is not defined. The measurements result in relative viscosity values, which cannot be compared with absolute values or other relative values if not determined by the same relative viscometer method.

Different measuring systems are available for given viscosity ranges as well as several rotational speeds.

APPARATUS

The following types of instruments are most common.

CONCENTRIC CYLINDER VISCOMETERS (ABSOLUTE VISCOMETERS)

In the concentric cylinder viscometer (coaxial double cylinder viscometer or simply coaxial cylinder viscometer), the viscosity is determined by placing the liquid in the gap between the inner cylinder and the outer cylinder. Viscosity measurement can be performed by rotating the inner cylinder (Searle type viscometer) or the outer cylinder (Couette type viscometer), as shown in Figures 2.2.10.-1 and 2.2.10.-2, respectively. For laminar flow, the viscosity (or apparent viscosity) η expressed in pascal-seconds is given by the following formula:

$$\eta = \frac{1}{\omega}\left(\frac{M}{4\pi h}\right)\left(\frac{1}{R_i^2} - \frac{1}{R_o^2}\right) = k\frac{M}{\omega}$$

M = torque in newton-metres acting on the cylinder surface,
ω = angular velocity in radians per second,
h = height of immersion in metres of the inner cylinder in the liquid medium,
R_i = radius in metres of the inner cylinder,
R_o = radius in metres of the outer cylinder,
k = constant of the apparatus, expressed in radians per cubic metre.

For non-Newtonian liquids it is indispensable to specify the shear stress (τ) or the shear rate (γ) at which the viscosity is measured. Under narrow gap conditions (conditions satisfied in absolute viscometers), there is a proportional relationship between *M* and τ and also between ω and γ:

$$\tau = AM \qquad \gamma = B\omega$$

where A and B are constants for the instrument and are calculated from the following expressions:

– *for concentric surface*:

$$A = \frac{1}{4\pi h}\frac{R_i^2 + R_0^2}{R_i^2 R_0^2} \qquad B = \frac{R_i^2 + R_0^2}{R_0^2 - R_i^2}$$

– *for cone-plates*:

$$A = \frac{3}{2\pi R^3} \qquad B = \frac{1}{\alpha}$$

M = torque in Newton-metres acting on the cone or cylinder surface,
ω = angular velocity in radians per second,
R_i = radius in metres of the inner cylinder,
R_0 = radius in metres of the outer cylinder,
R = radius in metres of the cone,
h = height of immersion in metres of the inner cylinder in the liquid medium,
α = angle in radians between the flat disk and the cone,
τ = shear stress in pascals (Pa),
γ = shear rate in reciprocal seconds (s^{-1}).

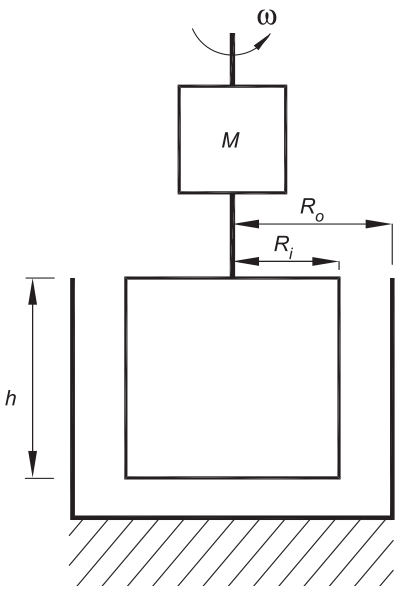

Figure 2.2.10.-1

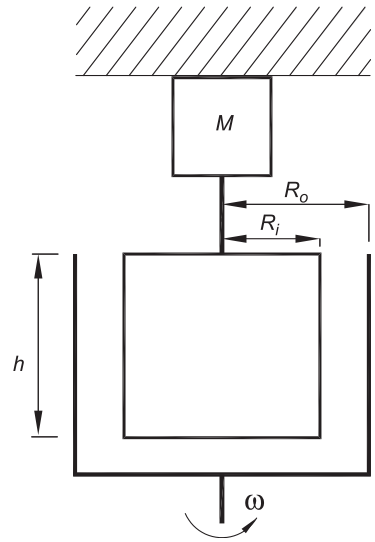

Figure 2.2.10.-2

CONE-PLATE VISCOMETERS (ABSOLUTE VISCOMETERS)

In the cone-plate viscometer, the liquid is introduced into the gap between a flat disc and a cone forming a define angle. Viscosity measurement can be performed by rotating the cone or the flat disc, as shown in Figures 2.2.10.-3 and 2.2.10.-4, respectively. For laminar flow, the viscosity (or apparent viscosity) η expressed in pascal-seconds is given by the following formula:

$$\eta = \left(\frac{M}{\omega}\right)\left(\frac{3\alpha}{2\pi R^3}\right) = k\frac{M}{\omega}$$

M = torque in Newton-metres acting on the flat disc or cone surface,
ω = angular velocity in radians per second,
α = angle in radians between the flat disc and the cone,
R = radius in metres of the cone,
k = constant of the apparatus, expressed in radians per cubic metre.

Constants *A*, *B* of the apparatus (see under concentric cylinder viscometers).

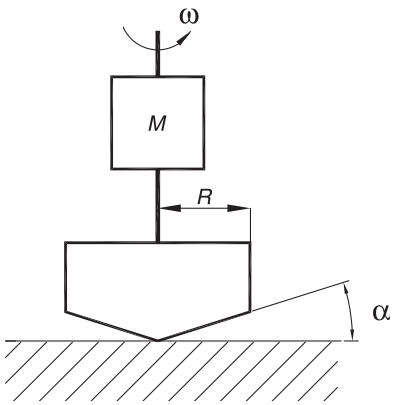

Figure 2.2.10.-3

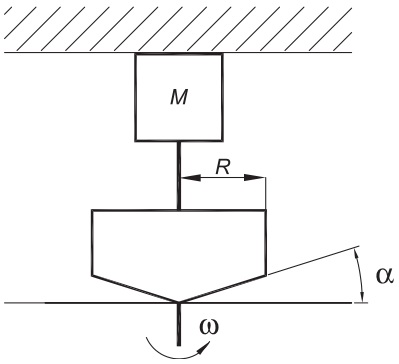

Figure 2.2.10.-4

SPINDLE VISCOMETERS (RELATIVE VISCOMETERS)

In the spindle viscometer, the viscosity is determined by rotating a spindle (for example, cylinder- or disc-shaped, as shown in Figures 2.2.10.-5 and 2.2.10.-6, respectively) immersed in the liquid. Relative values of viscosity (or apparent viscosity) can be directly calculated using conversion factors from the scale reading at a given rotational speed.

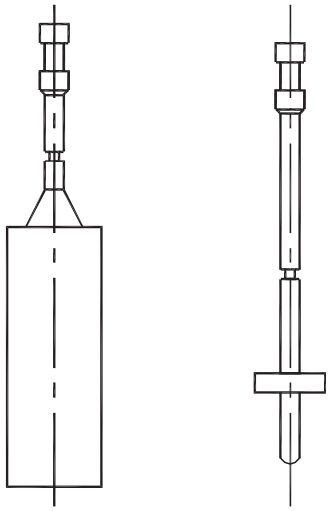

Figure 2.2.10.-5

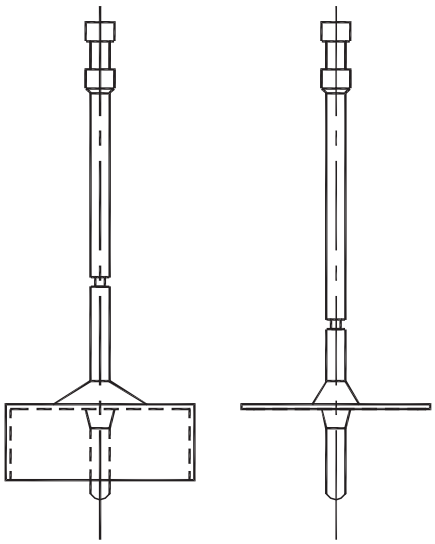

Figure 2.2.10.-6

In a general way, the constant k of the apparatus may be determined at various speeds of rotation using a certified viscometer calibration liquid. The viscosity η then corresponds to the formula:

$$\eta = k\frac{M}{\omega}$$

METHOD

Measure the viscosity (or apparent viscosity) according to the instructions for the operation of the rotating viscometer. The temperature for measuring the viscosity is indicated in the monograph. For non-Newtonian systems, the monograph indicates the type of viscometer to be used and if absolute viscometers are used the angular velocity or the shear rate at which the measurement is made. If it is impossible to obtain the indicated shear rate exactly, use a shear rate slightly higher and a shear rate slightly lower and interpolate.

With relative viscometers the shear rate is not the same throughout the sample and therefore it cannot be defined. Under these conditions, the viscosity of non-Newtonian liquids determined from the previous formula has a relative character, which depends on the type of spindle and the angular velocity as well as the dimensions of the sample container (Ø = minimum 80 mm) and the depth of immersion of the spindle. The values obtained are comparable only if the method is carried out under experimental conditions that are rigorously the same.

01/2008:20211

2.2.11. DISTILLATION RANGE

The distillation range is the temperature interval, corrected for a pressure of 101.3 kPa (760 Torr), within which a liquid, or a specified fraction of a liquid, distils in the following conditions.

Apparatus. The apparatus (see Figure 2.2.11.-1) consists of a distillation flask (*A*), a straight tube condenser (*B*) which fits on to the side arm of the flask and a plain-bend adaptor (*C*) attached to the end of the condenser. The lower end of the condenser may, alternatively, be bent to replace the adaptor. A thermometer is inserted in the neck of the flask so that the upper end of the mercury reservoir is 5 mm lower than the junction of the lower wall of the lateral tube. The thermometer is graduated at 0.2 °C intervals and the scale covers a range of about 50 °C. During the determination, the flask, including its neck, is protected from draughts by a suitable screen.

Method. Place in the flask (*A*) 50.0 ml of the liquid to be examined and a few pieces of porous material. Collect the distillate in a 50 ml cylinder graduated in 1 ml. Cooling by circulating water is essential for liquids distilling below 150 °C. Heat the flask so that boiling is rapidly achieved and note the temperature at which the first drop of distillate falls into the cylinder. Adjust the heating to give a regular rate of distillation of 2-3 ml/min and note the temperature when the whole or the prescribed fraction of the liquid, measured at 20 °C, has distilled.

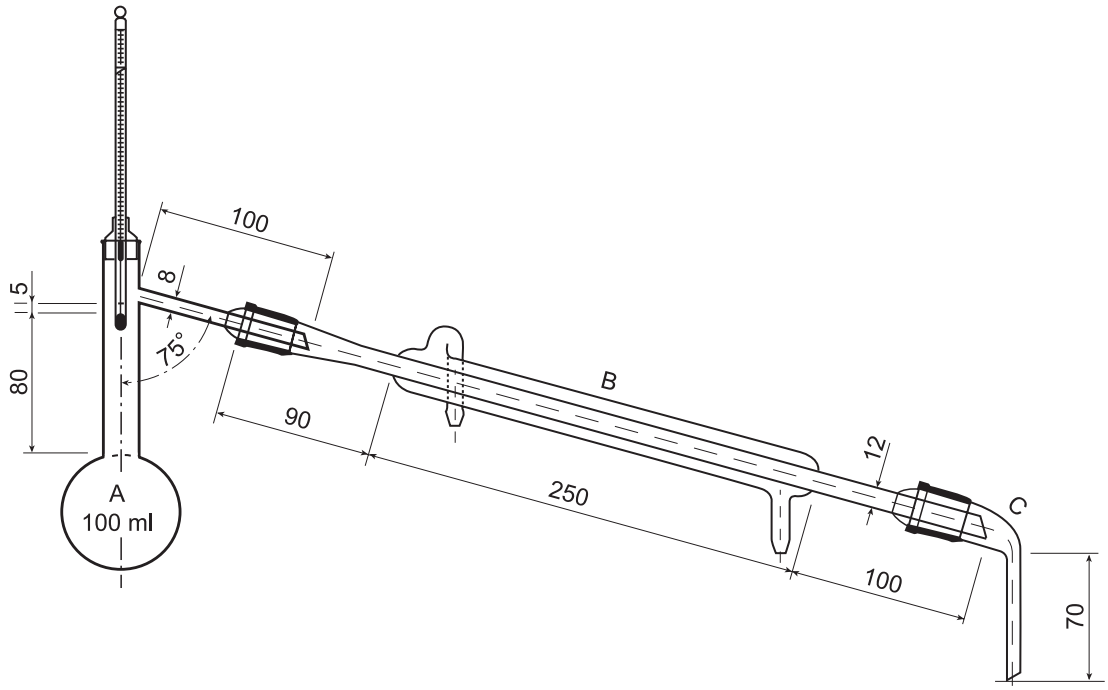

Figure 2.2.11.-1. – *Apparatus for the determination of distillation range*
Dimensions in millimetres

Table 2.2.11.-1. – *Temperature correction in relation to the pressure*

Distillation temperature	Correction factor *k*
up to 100 °C	0.30
above 100 °C up to 140 °C	0.34
above 140 °C up to 190 °C	0.38
above 190 °C up to 240 °C	0.41
above 240 °C	0.45

Correct the observed temperatures for barometric pressure by means of the formula:

$$t_1 = t_2 + k\,(101.3 - b)$$

t_1 = the corrected temperature,

t_2 = the observed temperature, at the barometric pressure b,

k = the correction factor taken from Table 2.2.11.-1 unless the factor is given,

b = the barometric pressure, expressed in kilopascals, during the distillation.

01/2008:20212

2.2.12. BOILING POINT

The boiling point is the corrected temperature at which the vapour pressure of a liquid is equal to 101.3 kPa.

Apparatus. The apparatus is that used for Distillation Range (*2.2.11*) with the exception that the thermometer is inserted in the neck of the flask so that the lower end of the mercury reservoir is level with the lower end of the neck of the distillation flask and that the flask is placed on a plate of isolating material pierced by a hole 35 mm in diameter.

Method. Place in the flask (*A*) 20 ml of the liquid to be examined and a few pieces of porous material. Heat the flask so that boiling is rapidly achieved and record the temperature at which liquid runs from the side-arm into the condenser.

Correct the observed temperature for barometric pressure by means of the formula:

$$t_1 = t_2 + k\,(101.3 - b)$$

t_1 = the corrected temperature,

t_2 = the observed temperature at barometric pressure b,

k = the correction factor as shown in Table 2.2.11.-1 under Distillation Range,

b = the barometric pressure, in kilopascals, at the time of the determination.

01/2008:20213

2.2.13. DETERMINATION OF WATER BY DISTILLATION

The apparatus (see Figure 2.2.13.-1) consists of a glass flask (*A*) connected by a tube (*D*) to a cylindrical tube (*B*) fitted with a graduated receiving tube (*E*) and reflux condenser (*C*). The receiving tube (*E*) is graduated in 0.1 ml. The source of heat is preferably an electric heater with rheostat control or an oil bath. The upper portion of the flask and the connecting tube may be insulated.

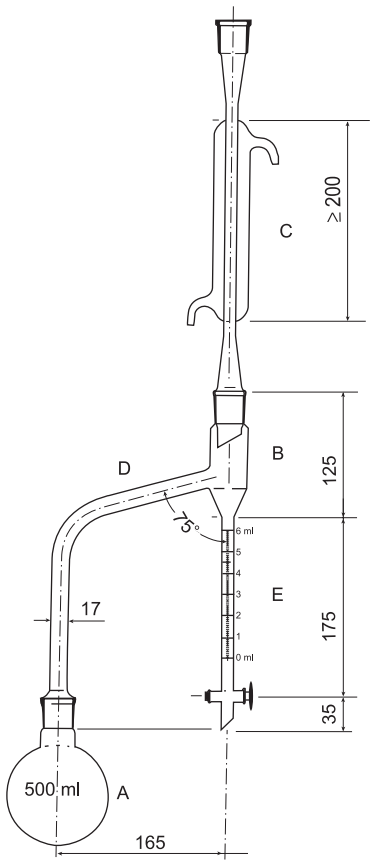

Figure 2.2.13.-1. – *Apparatus for the determination of water by distillation*

Dimensions in millimetres

Method. Clean the receiving tube and the condenser of the apparatus, thoroughly rinse with water, and dry.

Introduce 200 ml of *toluene R* and about 2 ml of *water R* into the dry flask. Distil for 2 h, then allow to cool for about 30 min and read the water volume to the nearest 0.05 ml. Place in the flask a quantity of the substance, weighed with an accuracy of 1 per cent, expected to give about 2 ml to 3 ml of water. If the substance has a pasty consistency, weigh it in a boat of metal foil. Add a few pieces of porous material and heat the flask gently for 15 min. When the toluene begins to boil, distil at the rate of about two drops per second until most of the water has distilled over, then increase the rate of distillation to about four drops per second. When the water has all distilled over, rinse the inside of the condenser tube with *toluene R*. Continue the distillation for 5 min, remove the heat, allow the receiving tube to cool to room temperature and dislodge any droplets of water which adhere to the walls of the receiving tube. When the water and toluene have completely separated, read the volume of water and calculate the content present in the substance as millilitre per kilogram, using the formula:

$$\frac{1000\,(n_2 - n_1)}{m}$$

m = the mass in grams of the substance to be examined,

n_1 = the number of millilitres of water obtained in the first distillation,

n_2 = the total number of millilitres of water obtained in the 2 distillations.

01/2008:20214

2.2.14. MELTING POINT - CAPILLARY METHOD

The melting point determined by the capillary method is the temperature at which the last solid particle of a compact column of a substance in a tube passes into the liquid phase.

When prescribed in the monograph, the same apparatus and method are used for the determination of other factors, such as meniscus formation or melting range, that characterise the melting behaviour of a substance.

Apparatus. The apparatus consists of:

– a suitable glass vessel containing a liquid bath (for example, water, liquid paraffin or silicone oil) and fitted with a suitable means of heating,

– a suitable means of stirring, ensuring uniformity of temperature within the bath,

– a suitable thermometer with graduation at not more than 0.5 °C intervals and provided with an immersion mark. The range of the thermometer is not more than 100 °C,

– alkali-free hard-glass capillary tubes of internal diameter 0.9 mm to 1.1 mm with a wall 0.10 mm to 0.15 mm thick and sealed at one end.

Method. Unless otherwise prescribed, dry the finely powdered substance *in vacuo* and over *anhydrous silica gel R* for 24 h. Introduce a sufficient quantity into a capillary tube to give a compact column 4 mm to 6 mm in height. Raise the temperature of the bath to about 10 °C below the presumed melting point and then adjust the rate of heating to about 1 °C/min. When the temperature is 5 °C below the presumed melting point, correctly introduce the capillary tube into the instrument. For the apparatus described above, immerse the capillary tube so that the closed end is near the centre of the bulb of the thermometer, the immersion mark of which is at the level of the surface of the liquid. Record the temperature at which the last particle passes into the liquid phase.

Calibration of the apparatus. The apparatus may be calibrated using melting point reference substances such as those of the World Health Organisation or other appropriate substances.

01/2008:20215

2.2.15. MELTING POINT - OPEN CAPILLARY METHOD

For certain substances, the following method is used to determine the melting point (also referred to as slip point and rising melting point when determined by this method).

Use glass capillary tubes open at both ends, about 80 mm long, having an external diameter of 1.4 mm to 1.5 mm and an internal diameter of 1.0 mm to 1.2 mm.

Introduce into each of 5 capillary tubes a sufficient amount of the substance, previously treated as described, to form in each tube a column about 10 mm high and allow the tubes to stand for the appropriate time and at the prescribed temperature.

Unless otherwise prescribed, substances with a waxy consistency are carefully and completely melted on a water-bath before introduction into the capillary tubes. Allow the tubes to stand at 2-8 °C for 2 h.

Attach one of the tubes to a thermometer graduated in 0.5 °C so that the substance is close to the bulb of the thermometer. Introduce the thermometer with the attached tube into a beaker so that the distance between the bottom of the beaker and the lower part of the bulb of the thermometer is 1 cm. Fill the beaker with water to a depth of 5 cm. Increase the temperature of the water gradually at a rate of 1 °C/min.

The temperature at which the substance begins to rise in the capillary tube is regarded as the melting point.

Repeat the operation with the other 4 capillary tubes and calculate the result as the mean of the 5 readings.

01/2008:20216

2.2.16. MELTING POINT - INSTANTANEOUS METHOD

The instantaneous melting point is calculated using the expression:

$$\frac{t_1 + t_2}{2}$$

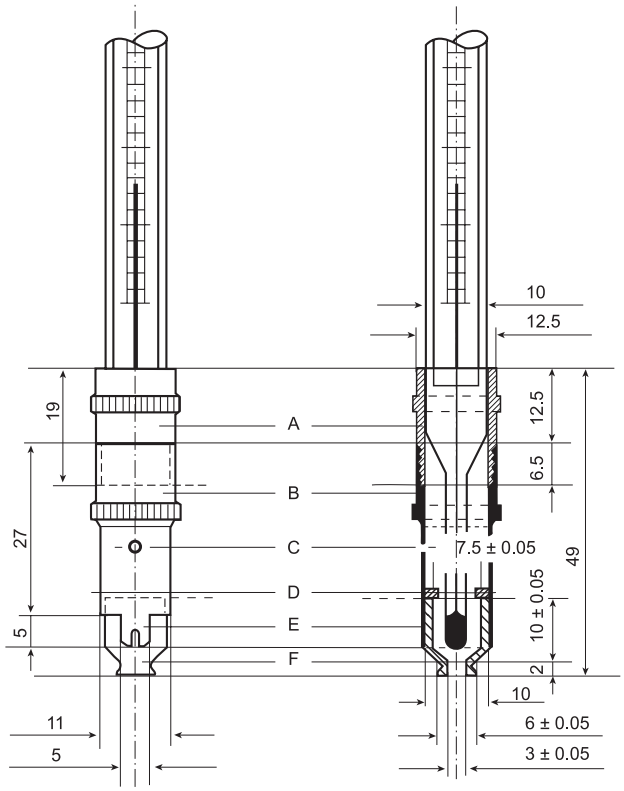
in which t_1 is the first temperature and t_2 the second temperature read under the conditions stated below.

Apparatus. The apparatus consists of a metal block resistant to the substance to be examined, of good heat-conducting capacity, such as brass, with a carefully polished plane upper surface. The block is uniformly heated throughout its mass by means of a micro-adjustable gas heater or an electric heating device with fine adjustment. The block has a cylindrical cavity, wide enough to accomodate a thermometer, which should be maintained with the mercury column in the same position during the calibration of the apparatus and the determination of the melting point of the substance to be examined. The cylindrical cavity is parallel to the upper polished surface of the block and about 3 mm from it. The apparatus is calibrated using appropriate substances of known melting point.

Method. Heat the block at a suitably rapid rate to a temperature about 10 °C below the presumed melting temperature, then adjust the heating rate to about 1 °C/min. At regular intervals drop a few particles of powdered and, where appropriate, dried substance, prepared as for the capillary tube method, onto the block in the vicinity of the thermometer bulb, cleaning the surface after each test. Record the temperature t_1 at which the substance melts instantaneously for the first time in contact with the metal. Stop the heating. During cooling drop a few particles of the substance at regular intervals on the block, cleaning the surface after each test. Record the temperature t_2 at which the substance ceases to melt instantaneously when it comes in contact with the metal

Calibration of the apparatus. The apparatus may be calibrated using melting point reference substances such as those of the World Health Organisation or other appropriate substances.

01/2008:20217



2.2.17. DROP POINT

The drop point is the temperature at which the first drop of the melting substance to be examined falls from a cup under defined conditions.

When a monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.

METHOD A

Apparatus. The apparatus (see Figure 2.2.17.-1) consists of 2 metal sheaths (*A* and *B*) screwed together. Sheath *A* is fixed to a mercury thermometer. A metal cup is loosely fixed to the lower part of sheath *B* by means of 2 tightening bands. Fixed supports 2 mm long determine the exact position of the cup, and in addition are used to centre the thermometer. A hole pierced in the wall of sheath *B* is used to balance the pressure. The draining surface of the cup must be flat and the edges of the outflow orifice must be at right angles to it. The lower part of the mercury thermometer has the form and size shown in the figure; it covers a range from 0 °C to 110 °C and on its scale a distance of 1 mm represents a difference of 1 °C. The mercury reservoir of the thermometer has a diameter of 3.5 ± 0.2 mm and a height of 6.0 ± 0.3 mm. The apparatus is placed in the axis of a test-tube about 200 mm long and with an external diameter of about 40 mm. It is fixed to the test-tube by means of a laterally grooved stopper through which the thermometer passes. The opening of the cup is placed about 15 mm from the bottom of the test-tube. The whole device is immersed in a beaker with a capacity of about 1 litre, filled with water. The bottom of the test-tube is placed about 25 mm from the bottom of the beaker. The water level reaches the upper part of sheath *A*. A stirrer is used to ensure that the temperature of the water remains uniform.

A. upper metal sheath
B. lower metal sheath
C. pressure-balancing hole
D. fixed supports
E. tightening bands
F. metal sample cup

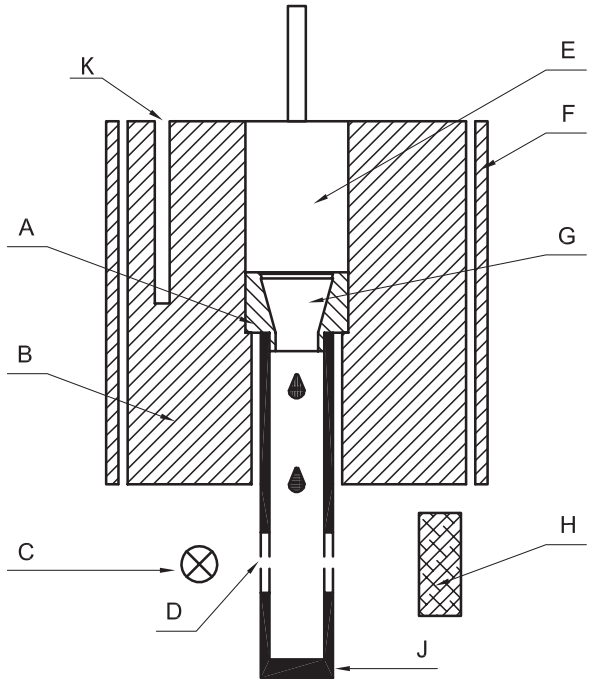


Figure 2.2.17.-1. – *Apparatus for the determination of drop point*

Dimensions in millimetres

Method. Prepare the substance to be examined according to the prescriptions of the monograph. Fill the cup to the brim with the substance to be examined. Remove the excess substance at the 2 ends of the cup with a spatula. When sheaths *A* and *B* have been assembled, press the cup into its housing in sheath *B* until it touches the supports. Remove with a spatula the substance pushed out by the thermometer. Place the apparatus in the water-bath as described above. Heat the water-bath and, when the temperature is at about 10 °C below the presumed drop point, adjust the heating rate to about 1 °C/min. Note the temperature at the fall of the first drop. Carry out at least 3 determinations, each time with a fresh sample of the substance. The difference between the readings must not exceed 3 °C. The mean of 3 readings is the drop point of the substance.

METHOD B - AUTOMATED METHOD

Apparatus. The apparatus (see Figure 2.2.17.-2) consists of a cartridge assembly comprising a cup holder into which the sample cup containing the sample is loosely fixed, and a collector sleeve with a horizontal light slit, which is fixed below the cup. This assembly is placed in a heating block. The block is a metal cylinder with a cylindrical hole along its vertical axis into which the cartridge assembly is placed. There is another, narrower cylindrical vertical hole in which a temperature sensor sits. This is positioned level with the sample cup. The heating block is surrounded by an electrical heating element. Below the heating block a lamp is mounted such that a beam of light shines through the light slit in the collector sleeve, and onto a photo-sensor mounted opposite. The heating block is capable of being maintained at a precise, pre-defined temperature by the heating element, and of being heated at a slow and steady, pre-defined rate after an initial isothermal period.

E. cartridge assembly
F. heating element
G. sample cup
H. photo-sensor
J. collector sleeve
K. temperature probe

Figure 2.2.17.-2. – *Example of automated drop point apparatus*

Method. Melt the substance to be examined and introduce it into the sample cup according to the prescriptions of the monograph, then proceed as follows or according to the manufacturer's instructions. Remove the excess substance at the 2 ends of the cup with a spatula. Condition the sample at the temperature and for the time prescribed in the monograph before making the measurement. Press the cup into the cup holder, and then press the collector sleeve onto the cup. Place the cartridge assembly in the heating block. Set the instrument to the initial isothermal conditions and rate for subsequent heating as described in the monograph of the substance to be examined. Start the temperature programme. When the first drop of molten sample falls through the hole at the bottom of the sample cup, interrupting the light beam, the signal from the photo-sensor causes the temperature of the heating block to be recorded automatically.

Calibration. Use the apparatus according to the manufacturer's instructions and carry out the prescribed calibrations and system performance tests at regular intervals, depending on the use of the apparatus and the substances to be examined. Benzoic acid and benzophenone are usually used as certified reference materials. Other materials may be used provided they show no polymorphism. Proceed as follows or according to the manufacturer's instructions. Prepare 3 sample cups for each of the 2 certified reference materials. Place the sample cups on a clean surface. Into each sample cup, introduce a small quantity of the sample and press it down with a rod (diameter about 4.5 mm). Check that the opening is completely filled. Fill the sample cup about half full and compact the sample with a rod (diameter about 9 mm). Fill the sample cup completely and compact, adding more sample and compacting again if necessary, until the sample cup is completely full.

Temperature programme for benzoic acid: start temperature = 118.0 °C; heating rate = 0.2 °C/min; end temperature = 126.0 °C. After inserting the cup at 118 °C, a waiting time of 30 s is set before heating starts.

Temperature programme for benzophenone: start temperature = 44.0 °C; heating rate = 0.2 °C/min; end temperature = 56.0 °C. After inserting the cup at 44 °C, a waiting time of 30 s is set before heating starts.

Check the 3 single results: the test is valid if the 3 results are within 0.3 °C of the mean value.

Calculate the corrected mean temperature $(T)_2$ using the following expression:

$$T_1 - F$$

T_1 = mean drop point temperature of 3 samples, in °C;

F = compensation for the difference in temperature between the sample and the point in the heating block where the temperature is measured; this will vary depending upon the design of the automatic drop point instrument and is provided by the manufacturer.

Taking into account the drop point (T_0) of the certified reference material, the accuracy of the temperature scale is satisfactory if $|T_2 - T_0|$ is not greater than 0.3 °C.

01/2008:20218

2.2.18. FREEZING POINT

The freezing point is the maximum temperature occurring during the solidification of a supercooled liquid.

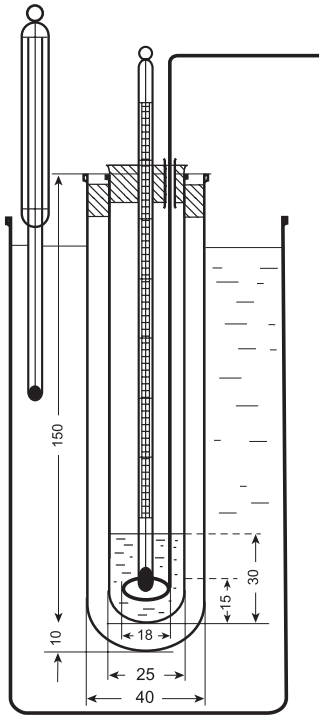

Figure 2.2.18.-1. – *Apparatus for the determination of freezing point*

Dimensions in millimetres

Apparatus. The apparatus (see Figure 2.2.18.-1) consists of a test-tube about 25 mm in diameter and 150 mm long placed inside a test-tube about 40 mm in diameter and 160 mm long. The inner tube is closed by a stopper which carries a thermometer about 175 mm long and graduated in 0.2 °C fixed so that the bulb is about 15 mm above the bottom of the tube. The stopper has a hole allowing the passage of the stem of a stirrer made from a glass rod or other suitable material formed at one end into a loop of about 18 mm overall diameter at right angles to the rod. The inner tube with its jacket is supported centrally in a 1 litre beaker containing a suitable cooling liquid to within 20 mm of the top. A thermometer is supported in the cooling bath.

Method. Place in the inner tube sufficient quantity of the liquid or previously melted substance to be examined, to cover the thermometer bulb and determine the approximate freezing point by cooling rapidly. Place the inner tube in a bath about 5 °C above the approximate freezing point until all but the last traces of crystals are melted. Fill the beaker with water or a saturated solution of sodium chloride, at a temperature about 5 °C lower than the expected freezing point, insert the inner tube into the outer tube, ensuring that some seed crystals are present, and stir thoroughly until solidification takes place. Note the highest temperature observed during solidification.

01/2008:20219

2.2.19. AMPEROMETRIC TITRATION

In amperometric titration the end-point is determined by following the variation of the current measured between 2 electrodes (either one indicator electrode and one reference electrode or 2 indicator electrodes) immersed in the solution to be examined and maintained at a constant potential difference as a function of the quantity of titrant added.

The potential of the measuring electrode is sufficient to ensure a diffusion current for the electroactive substance.

Apparatus. The apparatus comprises an adjustable voltage source and a sensitive microammeter; the detection system generally consists of an indicator electrode (for example, a platinum electrode, a dropping-mercury electrode, a rotating-disc electrode or a carbon electrode) and a reference electrode (for example, a calomel electrode or a silver-silver chloride electrode).

A three-electrode apparatus is sometimes used, consisting of an indicator electrode, a reference electrode and a polarised auxiliary electrode.

Method. Set the potential of the indicator electrode as prescribed and plot a graph of the initial current and the values obtained during the titration as functions of the quantity of titrant added. Add the titrant in not fewer than 3 successive quantities equal to a total of about 80 per cent of the theoretical volume corresponding to the presumed equivalence point. The 3 values must fall on a straight line. Continue adding the titrant beyond the presumed equivalence point in not fewer than 3 successive quantities. The values obtained must fall on a straight line. The point of intersection of the 2 lines represents the end-point of the titration.

For amperometric titration with 2 indicator electrodes, the whole titration curve is recorded and used to determine the end-point.

01/2008:20220
corrected 6.0

2.2.20. POTENTIOMETRIC TITRATION

In a potentiometric titration the end-point of the titration is determined by following the variation of the potential difference between 2 electrodes (either one indicator electrode and one reference electrode or 2 indicator electrodes) immersed in the solution to be examined as a function of the quantity of titrant added.

The potential is usually measured at zero or practically zero current.

Apparatus. The apparatus used (a simple potentiometer or electronic device) comprises a voltmeter allowing readings to the nearest millivolt.

The indicator electrode to be used depends on the substance to be determined and may be a glass or metal electrode (for example, platinum, gold, silver or mercury). The reference electrode is generally a calomel or a silver-silver chloride electrode.

For acid-base titrations and unless otherwise prescribed, a glass-calomel or glass-silver-silver chloride electrode combination is used.

Method. The solvent mixture is neutralised, if necessary, before dissolution of the substance to be examined. Plot a graph of the variation of potential difference as a function of the quantity of the titrant added, continuing the addition of the titrant beyond the presumed equivalence point. The end-point corresponds to a sharp variation of potential difference.

01/2008:20221

2.2.21. FLUORIMETRY

Fluorimetry is a procedure which uses the measurement of the intensity of the fluorescent light emitted by the substance to be examined in relation to that emitted by a given standard.

Method. Dissolve the substance to be examined in the solvent or mixture of solvents prescribed in the monograph, transfer the solution to the cell or the tube of the fluorimeter and illuminate it with an excitant light beam of the wavelength prescribed in the monograph and as near as possible monochromatic.

Measure the intensity of the emitted light at an angle of 90° to the excitant beam, after passing it through a filter which transmits predominantly light of the wavelength of the fluorescence. Other types of apparatus may be used provided that the results obtained are identical.

For quantitative determinations, first introduce into the apparatus the solvent or mixture of solvents used to dissolve the substance to be examined and set the instrument to zero. Introduce the standard solution and adjust the sensitivity of the instrument so that the reading is greater than 50. If the second adjustment is made by altering the width of the slits, a new zero setting must be made and the intensity of the standard must be measured again. Finally introduce the solution of unknown concentration and read the result on the instrument. Calculate the concentration c_x of the substance in the solution to be examined, using the formula:

$$c_x = \frac{I_x c_s}{I_s}$$

c_x = concentration of the solution to be examined,

c_s = concentration of the standard solution,

I_x = intensity of the light emitted by the solution to be examined,

I_s = intensity of the light emitted by the standard solution.

If the intensity of the fluorescence is not strictly proportional to the concentration, the measurement may be effected using a calibration curve.

In some cases, measurement can be made with reference to a fixed standard (for example a fluorescent glass or a solution of another fluorescent substance). In such cases, the concentration of the substance to be examined must be determined using a previously drawn calibration curve under the same conditions.

01/2008:20222

2.2.22. ATOMIC EMISSION SPECTROMETRY

GENERAL PRINCIPLE

Atomic emission is a process that occurs when electromagnetic radiation is emitted by excited atoms or ions. In atomic emission spectrometry the sample is subjected to temperatures high enough to cause not only dissociation into atoms, but also to cause significant amounts of collisional excitation and ionisation of the sample atoms to take place. Once the atoms and ions are in the excited states, they can decay to lower states through thermal or radiative (emission) energy transitions and electromagnetic radiation is emitted. An emission spectrum of an element contains several more lines than the corresponding absorption spectrum.

Atomic emission spectrometry is a technique for determining the concentration of an element in a sample by measuring the intensity of one of the emission lines of the atomic vapour of the element generated from the sample. The determination is carried out at the wavelength corresponding to this emission line.

In this chapter only atomisation in flame is dealt with. The method of inductively coupled plasma-atomic emission spectrometry (ICP-AES) is described in a different general chapter.

APPARATUS

This consists essentially of:

- a sample introduction and nebulisation system;
- a flame to generate the atoms to be determined;
- a monochromator;
- a detector;
- a data-acquisition unit.

Oxygen, air and a combustible gas such as hydrogen, acetylene, propane or butane may be used in flames. The atomisation source is critical, since it must provide sufficient energy to excite and atomise the atoms. The atomic spectra emitted from flames have the advantage of being simpler than those emitted from other sources, the main limitation being that the flames are not powerful enough to cause emission for many elements allowing their determination. Acidified water is the solvent of choice for preparing test and reference solutions, although organic solvents may also be used if precautions are taken to ensure that the solvent does not interfere with the stability of the flame.

INTERFERENCES

Spectral interference is reduced or eliminated by choosing an appropriate emission line for measurement or by adjusting the slit for spectral band-width. Physical interference is corrected by diluting the sample solution, by matching the matrix or by using the method of standard additions. Chemical interference is reduced by using chemical modifiers or ionisation buffers.

MEMORY EFFECT

The memory effect caused by deposit of analyte in the apparatus may be limited by thoroughly rinsing between runs, diluting the solutions to be measured if possible and thus reducing their salt content, and by aspirating the solutions through as swiftly as possible.

METHOD

Use of plastic labware is recommended wherever possible.

Operate an atomic emission spectrometer in accordance with the manufacturer's instructions at the prescribed wavelength. Optimise the experimental conditions (flame temperature, burner adjustment, use of an ionic buffer, concentration of solutions) for the specific element to be analysed and in respect of the sample matrix. Introduce a blank solution into the atomic generator and adjust the instrument reading to zero or to its blank value. Introduce the most concentrated reference solution and adjust the sensitivity to obtain a suitable reading.

It is preferable to use concentrations which fall within the linear part of the calibration curve. If this is not possible, the calibration plots may also be curved and are then to be applied with appropriate calibration software.

Determinations are made by comparison with reference solutions with known concentrations of the element to be determined either by the method of direct calibration (Method I) or the method of standard additions (Method II).

METHOD I - DIRECT CALIBRATION

For routine measurements 3 reference solutions of the element to be determined and a blank are prepared and examined.

Prepare the solution of the substance to be examined (test solution) as prescribed in the monograph. Prepare not fewer than 3 reference solutions of the element to be determined, the concentrations of which span the expected value in the test solution. For assay purposes, optimal calibration levels are between 0.7 and 1.3 times the expected content of the element to be determined or the limit prescribed in the monograph. For purity determination, calibration levels are between the limit of detection and 1.2 times the limit specified for the element to be determined. Any reagents used in the preparation of the test solution are added to the reference solutions and to the blank solution at the same concentration.

Introduce each of the solutions into the instrument using the same number of replicates for each solution, to obtain a steady reading.

Calculation. Prepare a calibration curve from the mean of the readings obtained with the reference solutions by plotting the means as a function of concentration. Determine the concentration of the element in the test solution from the curve obtained.

METHOD II - STANDARD ADDITIONS

Add to at least 3 similar volumetric flasks equal volumes of the solution of the substance to be examined (test solution) prepared as prescribed. Add to all but 1 of the flasks progressively larger volumes of a reference solution containing a known concentration of the element to be determined to produce a series of solutions containing steadily increasing concentrations of that element known to give responses in the linear part of the curve, if at all possible. Dilute the contents of each flask to volume with solvent.

Introduce each of the solutions into the instrument using the same number of replicates for each solution, to obtain a steady reading.

Calculation. Calculate the linear equation of the graph using a least-squares fit, and derive from it the concentration of the element to be determined in the test solution.

VALIDATION OF THE METHOD

Satisfactory performance of methods prescribed in monographs is verified at suitable time intervals.

LINEARITY

Prepare and analyse not fewer than 4 reference solutions over the calibration range and a blank solution. Perform not fewer than 5 replicates.

The calibration curve is calculated by least-square regression from all measured data. The regression curve, the means, the measured data and the confidence interval of the calibration curve are plotted. The operating method is valid when:

- the correlation coefficient is at least 0.99,
- the residuals of each calibration level are randomly distributed around the calibration curve.

Calculate the mean and relative standard deviation for the lowest and highest calibration level.

When the ratio of the estimated standard deviation of the lowest and the highest calibration level is less than 0.5 or greater than 2.0, a more precise estimation of the calibration curve may be obtained using weighted linear regression.

Both linear and quadratic weighting functions are applied to the data to find the most appropriate weighting function to be employed. If the means compared to the calibration curve show a deviation from linearity, two-dimensional linear regression is used.

ACCURACY

Verify the accuracy preferably by using a certified reference material (CRM). Where this is not possible, perform a test for recovery.

Recovery. For assay determinations a recovery of 90 per cent to 110 per cent is to be obtained. For other determinations, for example for trace element determination, the test is not valid if recovery is outside of the range 80 per cent to 120 per cent at the theoretical value. Recovery may be determined on a suitable reference solution (matrix solution) which is spiked with a known quantity of analyte (middle concentration of the calibration range).

REPEATABILITY

The repeatability is not greater than 3 per cent for an assay and not greater than 5 per cent for an impurity test.

LIMIT OF QUANTIFICATION

Verify that the limit of quantification (for example, determined using the 10 σ approach) is below the value to be measured.

01/2008:20223

2.2.23. ATOMIC ABSORPTION SPECTROMETRY

GENERAL PRINCIPLE

Atomic absorption is a process that occurs when a ground state-atom absorbs electromagnetic radiation of a specific wavelength and is elevated to an excited state. The atoms in the ground state absorb energy at their resonant frequency and the electromagnetic radiation is attenuated due to resonance absorption. The energy absorption is virtually a direct function of the number of atoms present.

This chapter provides general information and defines the procedures used in element determinations by atomic absorption spectrometry, either atomisation by flame, by electrothermal vaporisation in a graphite furnace, by hydride generation or by cold vapour technique for mercury.

Atomic absorption spectrometry is a technique for determining the concentration of an element in a sample by measuring the absorption of electromagnetic radiation by the atomic vapour of the element generated from the sample. The determination is carried out at the wavelength of one of the absorption (resonance) lines of the element concerned. The amount of radiation absorbed is, according to the Lambert-Beer law, proportional to the element concentration.

APPARATUS

This consists essentially of:

- a source of radiation;
- a sample introduction device;
- a sample atomiser;
- a monochromator or polychromator;
- a detector;
- a data-acquisition unit.

The apparatus is usually equipped with a background correction system. Hollow-cathode lamps and electrodeless discharge lamps (EDL) are used as radiation source. The

emission of such lamps consists of a spectrum showing very narrow lines with half-width of about 0.002 nm of the element being determined.

There are 3 types of sample atomisers:

– Flame technique

  A flame atomiser is composed of a nebulisation system with a pneumatic aerosol production accessory, a gas-flow regulation and a burner. Fuel-oxidant mixtures are commonly used to produce a range of temperatures from about 2000 K to 3000 K. Fuel gases include propane, hydrogen and acetylene; air and nitrous oxide are used as oxidants. The configuration of the burner is adapted to the gases used and the gas flow is adjustable. Samples are nebulised, acidified water being the solvent of choice for preparing test and reference solutions. Organic solvents may also be used if precautions are taken to ensure that the solvent does not interfere with the stability of the flame.

– Electrothermal atomisation technique

  An electrothermal atomiser is generally composed of a graphite tube furnace and an electric power source. Electrothermal atomisation in a graphite tube furnace atomises the entire sample and retains the atomic vapour in the light path for an extended period. This improves the detection limit. Samples, liquid as well as solid, are introduced directly into the graphite tube furnace, which is heated in a programmed series of steps to dry the sample and remove major matrix components by pyrolysis and to then atomise all of the analyte. The furnace is cleaned using a final temperature higher than the atomisation temperature. The flow of an inert gas during the pyrolysis step in the graphite tube furnace allows a better performance of the subsequent atomisation process.

– Cold vapour and hydride technique

  The atomic vapour may also be generated outside the spectrometer. This is notably the case for the cold-vapour method for mercury or for certain hydride-forming elements such as arsenic, antimony, bismuth, selenium and tin. For mercury, atoms are generated by chemical reduction with stannous chloride or sodium borohydride and the atomic vapour is swept by a stream of an inert gas into a cold quartz cell mounted in the optical path of the instrument. Hydrides thus generated are swept by an inert gas into a heated cell in which they are dissociated into atoms.

INTERFERENCES

Chemical, physical, ionisation and spectral interferences are encountered in atomic absorption measurements. Chemical interference is compensated by addition of matrix modifiers, of releasing agents or by using high temperature produced by a nitrous oxide-acetylene flame; the use of specific ionisation buffers (for example, lanthanum and caesium) compensates for ionisation interference; by dilution of the sample, through the method of standard additions or by matrix matching, physical interference due to high salt content or viscosity is eliminated. Spectral interference results from the overlapping of resonance lines and can be avoided by using a different resonance line. The use of Zeeman background correction also compensates for spectral interference and interferences from molecular absorption, especially when using the electrothermal atomisation technique. The use of multi-element hollow-cathode lamps may also cause spectral interference. Specific or non-specific absorption is measured in a spectral range defined by the band-width selected by the monochromator (0.2-2 nm).

BACKGROUND CORRECTION

Scatter and background in the flame or the electrothermal atomisation technique increase the measured absorbance values. Background absorption covers a large range of wavelengths, whereas atomic absorption takes place in a very narrow wavelength range of about 0.005-0.02 nm. Background absorption can in principle be corrected by using a blank solution of exactly the same composition as the sample, but without the specific element to be determined, although this method is frequently impracticable. With the electrothermal atomisation technique the pyrolysis temperature is to be optimised to eliminate the matrix decomposition products causing background absorption. Background correction can also be made by using 2 different light sources, the hollow-cathode lamp that measures the total absorption (element + background) and a deuterium lamp with a continuum emission from which the background absorption is measured. Background is corrected by subtracting the deuterium lamp signal from the hollow-cathode lamp signal. This method is limited in the spectral range on account of the spectra emitted by a deuterium lamp from 190-400 nm. Background can also be measured by taking readings at a non-absorbing line near the resonance line and then subtracting the results from the measurement at the resonance line. Another method for the correction of background absorption is the Zeeman effect (based on the Zeeman splitting of the absorption line in a magnetic field). This is particularly useful when the background absorption shows fine structure. It permits an efficient background correction in the range of 185-900 nm.

CHOICE OF THE OPERATING CONDITIONS

After selecting the suitable wavelength and slit width for the specific element, the need for the following has to be ascertained:

– correction for non-specific background absorption,
– chemical modifiers or ionisation buffers to be added to the sample as well as to blank and reference solutions,
– dilution of the sample to minimise, for example, physical interferences,
– details of the temperature programme, preheating, drying, pyrolysis, atomisation, post-atomisation with ramp and hold times,
– inert gas flow,
– matrix modifiers for electrothermal atomisation (furnace),
– chemical reducing reagents for measurements of mercury or other hydride-forming elements along with cold vapour cell or heating cell temperature,
– specification of furnace design (tank, L'vov platform, etc).

METHOD

Use of plastic labware is recommended wherever possible. The preparation of the sample may require a dissolution, a digestion (mostly microwave-assisted), an ignition step or a combination thereof in order to clear up the sample matrix and/or to remove carbon-containing material. If operating in an open system, the ignition temperature should not exceed 600 °C, due to the volatility of some metals, unless otherwise stated in the monograph.

Operate an atomic absorption spectrometer in accordance with the manufacturer's instructions at the prescribed wavelength. Introduce a blank solution into the atomic generator and adjust the instrument reading so that it indicates maximum transmission. The blank value may be determined by using solvent to zero the apparatus. Introduce the most concentrated reference solution and adjust the

sensitivity to obtain a maximum absorbance reading. Rinse in order to avoid contamination and memory effects. After completing the analysis, rinse with *water R* or acidified water.

If a solid sampling technique is applied, full details of the procedure are provided in the monograph.

Ensure that the concentrations to be determined fall preferably within the linear part of the calibration curve. If this is not possible, the calibration plots may also be curved and are then to be applied with appropriate calibration software.

Determinations are made by comparison with reference solutions with known concentrations of the element to be determined either by the method of direct calibration (Method I) or the method of standard additions (Method II).

METHOD I - DIRECT CALIBRATION

For routine measurements 3 reference solutions and a blank solution are prepared and examined.

Prepare the solution of the substance to be examined (test solution) as prescribed in the monograph. Prepare not fewer than 3 reference solutions of the element to be determined, the concentrations of which span the expected value in the test solution. For assay purposes, optimal calibration levels are between 0.7 and 1.3 times the expected content of the element to be determined or the limit prescribed in the monograph. For purity determination, calibration levels are the limit of detection and 1.2 times the limit specified for the element to be determined. Any reagents used in the preparation of the test solution are added to the reference and blank solutions at the same concentration.

Introduce each of the solutions into the instrument using the same number of replicates for each of the solutions to obtain a steady reading.

Calculation. Prepare a calibration curve from the mean of the readings obtained with the reference solutions by plotting the means as a function of concentration. Determine the concentration of the element in the test solution from the curve obtained.

METHOD II - STANDARD ADDITIONS

Add to at least 3 similar volumetric flasks equal volumes of the solution of the substance to be examined (test solution) prepared as prescribed. Add to all but 1 of the flasks progressively larger volumes of a reference solution containing a known concentration of the element to be determined to produce a series of solutions containing steadily increasing concentrations of that element known to give responses in the linear part of the curve, if possible. Dilute the contents of each flask to volume with solvent.

Introduce each of the solutions into the instrument, using the same number of replicates for each of the solutions, to obtain a steady reading.

Calculation. Calculate the linear equation of the graph using a least-squares fit and derive from it the concentration of the element to be determined in the test solution.

VALIDATION OF THE METHOD

Satisfactory performance of methods prescribed in monographs is verified at suitable time intervals.

LINEARITY

Prepare and analyse not fewer than 4 reference solutions over the calibration range and a blank solution. Perform not fewer than 5 replicates.

The calibration curve is calculated by least-square regression from all measured data. The regression curve, the means, the measured data and the confidence interval of the calibration curve are plotted. The operating method is valid when:

– the correlation coefficient is at least 0.99,
– the residuals of each calibration level are randomly distributed around the calibration curve.

Calculate the mean and relative standard deviation for the lowest and highest calibration level.

When the ratio of the estimated standard deviation of the lowest and the highest calibration level is less than 0.5 or greater than 2.0, a more precise estimation of the calibration curve may be obtained using weighted linear regression. Both linear and quadratic weighting functions are applied to the data to find the most appropriate weighting function to be employed. If the means compared to the calibration curve show a deviation from linearity, two-dimensional linear regression is used.

ACCURACY

Verify the accuracy preferably by using a certified reference material (CRM). Where this is not possible, perform a test for recovery.

Recovery. For assay determinations a recovery of 90 per cent to 110 per cent is to be obtained. For other determinations, for example, for trace element determination the test is not valid if recovery is outside of the range 80 per cent to 120 per cent at the theoretical value. Recovery may be determined on a suitable reference solution (matrix solution) which is spiked with a known quantity of analyte (middle concentration of the calibration range).

REPEATABILITY

The repeatability is not greater than 3 per cent for an assay and not greater than 5 per cent for an impurity test.

LIMIT OF QUANTIFICATION

Verify that the limit of quantification (for example, determined using the 10 σ approach) is below the value to be measured.

01/2008:20224

2.2.24. ABSORPTION SPECTROPHOTOMETRY, INFRARED

Infrared spectrophotometers are used for recording spectra in the region of 4000-650 cm^{-1} (2.5-15.4 μm) or in some cases down to 200 cm^{-1} (50 μm).

APPARATUS

Spectrophotometers for recording spectra consist of a suitable light source, monochromator or interferometer and detector.

Fourier transform spectrophotometers use polychromatic radiation and calculate the spectrum in the frequency domain from the original data by Fourier transformation. Spectrophotometers fitted with an optical system capable of producing monochromatic radiation in the measurement region may also be used. Normally the spectrum is given as a function of transmittance, the quotient of the intensity of the transmitted radiation and the incident radiation. It may also be given in absorbance.

The absorbance (A) is defined as the logarithm to base 10 of the reciprocal of the transmittance (T):

$$A = \log_{10}\left(\frac{1}{T}\right) = \log_{10}\left(\frac{I_0}{I}\right)$$

$T = \frac{I}{I_0}$,

I_0 = intensity of incident radiation,

I = intensity of transmitted radiation.

PREPARATION OF THE SAMPLE

FOR RECORDING BY TRANSMISSION OR ABSORPTION

Prepare the substance by one of the following methods.

Liquids. Examine a liquid either in the form of a film between 2 plates transparent to infrared radiation, or in a cell of suitable path length, also transparent to infrared radiation.

Liquids or solids in solution. Prepare a solution in a suitable solvent. Choose a concentration and a path length of the cell which give a satisfactory spectrum. Generally, good results are obtained with concentrations of 10-100 g/l for a path length of 0.5-0.1 mm. Absorption due to the solvent is compensated by placing in the reference beam a similar cell containing the solvent used. If an FT-IR instrument is used, the absorption is compensated by recording the spectra for the solvent and the sample successively. The solvent absorbance, corrected by a compensation factor, is subtracted using calculation software.

Solids. Examine solids dispersed in a suitable liquid (mull) or in a solid (halide disc), as appropriate. If prescribed in the monograph, make a film of a molten mass between 2 plates transparent to infrared radiation.

A. Mull

Triturate a small quantity of the substance to be examined with the minimum quantity of *liquid paraffin R* or other suitable liquid; 5-10 mg of the substance to be examined is usually sufficient to make an adequate mull using one drop of *liquid paraffin R*. Compress the mull between 2 plates transparent to infrared radiation.

B. Disc

Triturate 1-2 mg of the substance to be examined with 300-400 mg, unless otherwise specified, of finely powdered and dried *potassium bromide R* or *potassium chloride R*. These quantities are usually sufficient to give a disc of 10-15 mm diameter and a spectrum of suitable intensity. If the substance is a hydrochloride, it is recommended to use *potassium chloride R*. Carefully grind the mixture, spread it uniformly in a suitable die, and submit it to a pressure of about 800 MPa (8 t·cm^{-2}). For substances that are unstable under normal atmospheric conditions or are hygroscopic, the disc is pressed *in vacuo*. Several factors may cause the formation of faulty discs, such as insufficient or excessive grinding, humidity or other impurities in the dispersion medium or an insufficient reduction of particle size. A disc is rejected if visual examination shows lack of uniform transparency or when transmittance at about 2000 cm^{-1} (5 µm) in the absence of a specific absorption band is less than 60 per cent without compensation, unless otherwise prescribed.

Gases. Examine gases in a cell transparent to infrared radiation and having an optical path length of about 100 mm. Evacuate the cell and fill to the desired pressure through a stopcock or needle valve using a suitable gas transfer line between the cell and the container of the gas to be examined.

If necessary adjust the pressure in the cell to atmospheric pressure using a gas transparent to infrared radiation (for example *nitrogen R* and *argon R*). To avoid absorption interferences due to water, carbon dioxide or other atmospheric gases, place in the reference beam, if possible, an identical cell that is either evacuated or filled with the gas transparent to infrared radiation.

FOR RECORDING BY DIFFUSE REFLECTANCE

Solids. Triturate a mixture of the substance to be examined with finely powdered and dried *potassium bromide R* or *potassium chloride R*. Use a mixture containing approximately 5 per cent of the substance, unless otherwise specified. Grind the mixture, place it in a sample cup and examine the reflectance spectrum.

The spectrum of the sample in absorbance mode may be obtained after mathematical treatment of the spectra by the Kubelka-Munk function.

FOR RECORDING BY ATTENUATED TOTAL REFLECTION

Attenuated total reflection (including multiple reflection) involves light being reflected internally by a transmitting medium, typically for a number of reflections. However, several accessories exist where only one reflection occurs.

Prepare the substance as follows. Place the substance to be examined in close contact with an internal reflection element (IRE) such as diamond, germanium, zinc selenide, thallium bromide-thallium iodide (KRS-5) or another suitable material of high refractive index. Ensure close and uniform contact between the substance and the whole crystal surface of the internal reflection element, either by applying pressure or by dissolving the substance in an appropriate solvent, then covering the IRE with the obtained solution and evaporating to dryness. Examine the attenuated total reflectance (ATR) spectrum.

IDENTIFICATION USING REFERENCE SUBSTANCES

Prepare the substance to be examined and the reference substance by the same procedure and record the spectra between 4000-650 cm^{-1} (2.5-15.4 µm) under the same operational conditions. The transmission minima (absorption maxima) in the spectrum obtained with the substance to be examined correspond in position and relative size to those in the spectrum obtained with the reference substance (*CRS*).

When the spectra recorded in the solid state show differences in the positions of the transmission minima (absorption maxima), treat the substance to be examined and the reference substance in the same manner so that they crystallise or are produced in the same form, or proceed as prescribed in the monograph, then record the spectra.

IDENTIFICATION USING REFERENCE SPECTRA

Control of resolution performance. For instruments having a monochromator, record the spectrum of a polystyrene film approximately 35 µm in thickness. The difference x (see Figure 2.2.24.-1) between the percentage transmittance at the transmission maximum A at 2870 cm^{-1} (3.48 µm) and that at the transmission minimum B at 2849.5 cm^{-1} (3.51 µm) must be greater than 18. The difference y between the percentage transmittance at the transmission maximum C at 1589 cm^{-1} (6.29 µm) and that at the transmission minimum D at 1583 cm^{-1} (6.32 µm) must be greater than 10.

For Fourier-transform instruments, use suitable instrument resolution with the appropriate apodisation prescribed by the manufacturer. The resolution is checked by suitable means, for example by recording the spectrum of a polystyrene film approximately 35 µm in thickness. The difference between the absorbances at the absorption minimum at 2870 cm^{-1} and the absorption maximum at 2849.5 cm^{-1} is greater than 0.33. The difference between the absorbances at the absorption minimum at 1589 cm^{-1} and the absorption maximum at 1583 cm^{-1} is greater than 0.08.

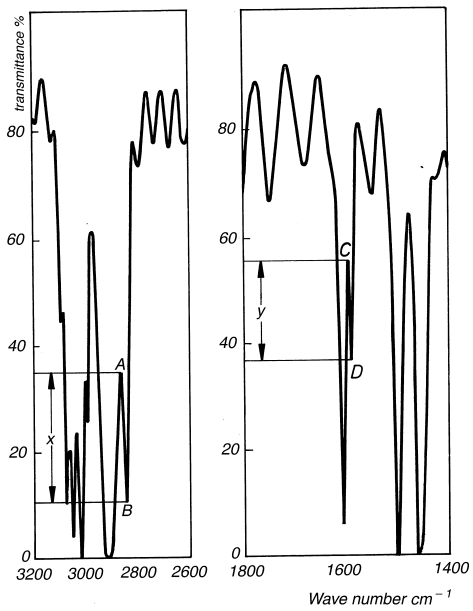

Figure 2.2.24.-1. — *Typical spectrum of polystyrene used to verify the resolution performance*

Verification of the wave-number scale. The wave-number scale may be verified using a polystyrene film, which has transmission minima (absorption maxima) at the wave numbers (in cm^{-1}) shown in Table 2.2.24.-1.

Table 2.2.24.-1. — *Transmission minima and acceptable tolerances of a polystyrene film*

Transmission minima (cm^{-1})	Acceptable tolerance (cm^{-1})	
	Monochromator instruments	Fourier-transform instruments
3060.0	± 1.5	± 1.0
2849.5	± 2.0	± 1.0
1942.9	± 1.5	± 1.0
1601.2	± 1.0	± 1.0
1583.0	± 1.0	± 1.0
1154.5	± 1.0	± 1.0
1028.3	± 1.0	± 1.0

Method. Prepare the substance to be examined according to the instructions accompanying the reference spectrum/reference substance. Using the operating conditions that were used to obtain the reference spectrum, which will usually be the same as those for verifying the resolution performance, record the spectrum of the substance to be examined.

The positions and the relative sizes of the bands in the spectrum of the substance to be examined and the reference spectrum are concordant in the 2 spectra.

Compensation for water vapour and atmospheric carbon dioxide. For Fourier-transform instruments, spectral interference from water vapour and carbon dioxide is compensated using suitable algorithms according to the manufacturer's instructions. Alternatively, spectra can be acquired using suitable purged instruments or ensuring that sample and background single beam spectra are acquired under exactly the same conditions.

IMPURITIES IN GASES

For the analysis of impurities, use a cell transparent to infrared radiation and of suitable optical path length (for example, 1-20 m). Fill the cell as prescribed under Gases. For detection and quantification of the impurities, proceed as prescribed in the monograph.

01/2008:20225

2.2.25. ABSORPTION SPECTROPHOTOMETRY, ULTRAVIOLET AND VISIBLE

Determination of absorbance. The absorbance (A) of a solution is defined as the logarithm to base 10 of the reciprocal of the transmittance (T) for monochromatic radiation:

$$A = \log_{10}\left(\frac{1}{T}\right) = \log_{10}\left(\frac{I_0}{I}\right)$$

T = I/I_0;

I_0 = intensity of incident monochromatic radiation;

I = intensity of transmitted monochromatic radiation.

In the absence of other physico-chemical factors, the absorbance (A) is proportional to the path length (b) through which the radiation passes and to the concentration (c) of the substance in solution in accordance with the equation:

$$A = \varepsilon c b$$

ϵ = molar absorptivity, if b is expressed in centimetres and c in moles per litre.

The expression $A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}}$ representing the specific absorbance of a dissolved substance refers to the absorbance of a 10 g/l solution in a 1 cm cell and measured at a defined wavelength so that:

$$A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}} = \frac{10\varepsilon}{M_\mathrm{r}}$$

Unless otherwise prescribed, measure the absorbance at the prescribed wavelength using a path length of 1 cm. Unless otherwise prescribed, the measurements are carried out with reference to the same solvent or the same mixture of solvents. The absorbance of the solvent measured against air and at the prescribed wavelength shall not exceed 0.4 and is preferably less than 0.2. Plot the absorption spectrum with absorbance or function of absorbance as ordinate against wavelength or function of wavelength as abscissa.

Where a monograph gives a single value for the position of an absorption maximum, it is understood that the value obtained may differ by not more than ± 2 nm.

Apparatus. Spectrophotometers suitable for measuring in the ultraviolet and visible range of the spectrum consist of an optical system capable of producing monochromatic radiation in the range of 200-800 nm and a device suitable for measuring the absorbance.

Control of wavelengths. Verify the wavelength scale using the absorption maxima of *holmium perchlorate solution R*, the line of a hydrogen or deuterium discharge lamp or the lines of a mercury vapour arc shown in Table 2.2.25.-1. The

permitted tolerance is ± 1 nm for the ultraviolet range and ± 3 nm for the visible range. Suitable certified reference materials may also be used.

Table 2.2.25.-1. — *Absorption maxima for control of wavelength scale*

241.15 nm (Ho)	404.66 nm (Hg)
253.7 nm (Hg)	435.83 nm (Hg)
287.15 nm (Ho)	486.0 nm (Dβ)
302.25 nm (Hg)	486.1 nm (Hβ)
313.16 nm (Hg)	536.3 nm (Ho)
334.15 nm (Hg)	546.07 nm (Hg)
361.5 nm (Ho)	576.96 nm (Hg)
365.48 nm (Hg)	579.07 nm (Hg)

Control of absorbance. Check the absorbance using suitable filters or a solution of *potassium dichromate R* at the wavelengths indicated in Table 2.2.25.-2, which gives for each wavelength the exact value and the permitted limits of the specific absorbance. The table is based on a tolerance for the absorbance of ± 0.01.

For the control of absorbance, use solutions of *potassium dichromate R* that has been previously dried to constant mass at 130 °C. For the control of absorbance at 235 nm, 257 nm, 313 nm and 350 nm, dissolve 57.0-63.0 mg of *potassium dichromate R* in *0.005 M sulphuric acid* and dilute to 1000.0 ml with the same acid. For the control of absorbance at 430 nm, dissolve 57.0-63.0 mg of *potassium dichromate R* in *0.005 M sulphuric acid* and dilute to 100.0 ml with the same acid. Suitable certified reference materials may also be used.

Table 2.2.25.-2

Wavelength (nm)	Specific absorbance $A_{1\ cm}^{1\ per\ cent}$	Maximum tolerance
235	124.5	122.9 to 126.2
257	144.5	142.8 to 146.2
313	48.6	47.0 to 50.3
350	107.3	105.6 to 109.0
430	15.9	15.7 to 16.1

Limit of stray light. Stray light may be detected at a given wavelength with suitable filters or solutions: for example, the absorbance of a 12 g/l solution of *potassium chloride R* in a 1 cm cell increases steeply between 220 nm and 200 nm and is greater than 2.0 at 198 nm when compared with water as compensation liquid. Suitable certified reference materials may also be used.

Resolution (for qualitative analysis). When prescribed in a monograph, measure the resolution of the apparatus as follows: record the spectrum of a 0.02 per cent *V/V* solution of *toluene R* in *hexane R*. The minimum ratio of the absorbance at the maximum at 269 nm to that at the minimum at 266 nm is stated in the monograph. Suitable certified reference materials may also be used.

Spectral slit-width (for quantitative analysis). To avoid errors due to spectral slit-width, when using an instrument on which the slit-width is variable at the selected wavelength, the slit-width must be small compared with the half-width of the absorption band but it must be as large as possible to obtain a high value of I_0. Therefore, a slit-width is chosen such that further reduction does not result in a change in absorbance reading.

Cells. The tolerance on the path length of the cells used is ± 0.005 cm. When filled with the same solvent, the cells intended to contain the solution to be examined and the compensation liquid must have the same transmittance. If this is not the case, an appropriate correction must be applied.

The cells must be cleaned and handled with care.

DERIVATIVE SPECTROPHOTOMETRY

Derivative spectrophotometry involves the transformation of absorption spectra (zero-order) into first-, second- or higher-order-derivative spectra.

A *first-order-derivative spectrum* is a plot of the gradient of the absorption curve (rate of change of the absorbance with wavelength, $dA/d\lambda$) against wavelength.

A *second-order-derivative spectrum* is a plot of the curvature of the absorption spectrum against wavelength ($d^2A/d\lambda^2$). The second-order-derivative spectrum at any wavelength λ is related to concentration by the following equation:

$$\frac{d^2A}{d\lambda^2} = \frac{d^2A_{1\ cm}^{1\ per\ cent}}{d\lambda^2} \times \frac{c'b}{10} = \frac{d^2A\varepsilon}{d\lambda^2} \times \frac{cb}{10}$$

c' = concentration of the absorbing solute, in grams per litre.

Apparatus. Use a spectrophotometer complying with the requirements prescribed above and equipped with an analogue resistance-capacitance differentiation module or a digital differentiator or other means of producing derivative spectra. Some methods of producing second-order-derivative spectra produce a wavelength shift relative to the zero-order spectrum and this is to be taken into account where applicable.

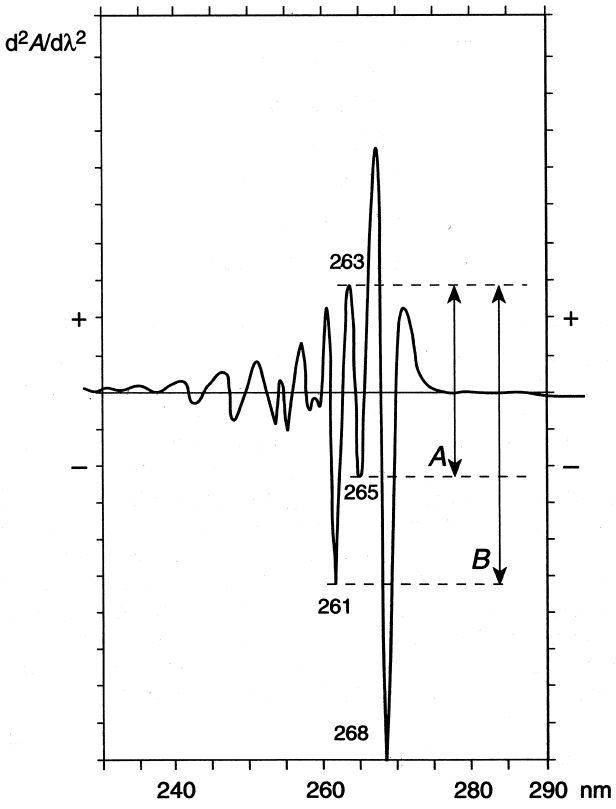

Figure 2.2.25.-1

Resolution power. When prescribed in a monograph, record the second-order-derivative spectrum of a 0.02 per cent *V/V* solution of *toluene R* in *methanol R*, using

methanol R as the compensation liquid. The spectrum shows a small negative extremum located between 2 large negative extrema at 261 nm and 268 nm, respectively, as shown in Figure 2.2.25.-1. Unless otherwise prescribed in the monograph, the ratio *A/B* (see Figure 2.2.25.-1) is not less than 0.2.

Procedure. Prepare the solution of the substance to be examined, adjust the various instrument settings according to the manufacturer's instructions, and calculate the amount of the substance to be determined as prescribed in the monograph.

01/2008:20226

2.2.26. PAPER CHROMATOGRAPHY

ASCENDING PAPER CHROMATOGRAPHY

Apparatus. The apparatus consists of a glass tank of suitable size for the chromatographic paper used, ground at the top to take a closely fitting lid. In the top of the tank is a device which suspends the chromatographic paper and is capable of being lowered without opening the chamber. In the bottom of the tank is a dish to contain the mobile phase into which the paper may be lowered. The chromatographic paper consists of suitable filter paper, cut into strips of sufficient length and not less than 2.5 cm wide; the paper is cut so that the mobile phase runs in the direction of the grain of the paper.

Method. Place in the dish a layer 2.5 cm deep of the mobile phase prescribed in the monograph. If prescribed in the monograph, pour the stationary phase between the walls of the tank and the dish. Close the tank and allow to stand for 24 h at 20 °C to 25 °C. Maintain the tank at this temperature throughout the subsequent procedure. Draw a fine pencil line horizontally across the paper 3 cm from one end. Using a micro pipette, apply to a spot on the pencil line the volume of the solution prescribed in the monograph. If the total volume to be applied would produce a spot more than 10 mm in diameter, apply the solution in portions allowing each to dry before the next application. When more than one chromatogram is to be run on the same strip of paper, space the solutions along the pencil line at points not less than 3 cm apart. Insert the paper into the tank, close the lid and allow to stand for 1 h 30 min. Lower the paper into the mobile phase and allow elution to proceed for the prescribed distance or time. Remove the paper from the tank and allow to dry in air. Protect the paper from bright light during the elution process.

DESCENDING PAPER CHROMATOGRAPHY

Apparatus. The apparatus consists of a glass tank of suitable size for the chromatographic paper used, ground at the top to take a closely fitting glass lid. The lid has a central hole about 1.5 cm in diameter closed by a heavy glass plate or a stopper. In the upper part of the tank is suspended a solvent trough with a device for holding the chromatographic paper. On each side of the trough, parallel to and slightly above its upper edges, are two glass guide rods to support the paper in such a manner that no part of it is in contact with the walls of the tank. The chromatographic paper consists of suitable filter paper, cut into strips of sufficient length, and of any convenient width between 2.5 cm and the length of the trough; the paper is cut so that the mobile phase runs in the direction of the grain of the paper.

Method. Place in the bottom of the tank a layer 2.5 cm deep of the solvent prescribed in the monograph, close the tank and allow to stand for 24 h at 20 °C to 25 °C. Maintain the tank at this temperature throughout the subsequent procedure. Draw a fine pencil line horizontally across the paper at such a distance from one end that when this end is secured in the solvent trough and the remainder of the paper is hanging freely over the guide rod, the line is a few centimetres below the guide rod and parallel with it. Using a micro-pipette, apply on the pencil line the volume of the solution prescribed in the monograph. If the total volume to be applied would produce a spot more than 10 mm in diameter, apply the solution in portions, allowing each to dry before the next application. When more than one chromatogram is to be run on the same strip of paper, space the solutions along the pencil line at points not less than 3 cm apart. Insert the paper in the tank, close the lid, and allow to stand for 1 h 30 min. Introduce into the solvent trough, through the hole in the lid, a sufficient quantity of the mobile phase, close the tank and allow elution to proceed for the prescribed distance or time. Remove the paper from the tank and allow to dry in air. The paper should be protected from bright light during the elution process.

01/2008:20227

2.2.27. THIN-LAYER CHROMATOGRAPHY

Thin-layer chromatography is a separation technique in which a stationary phase consisting of an appropriate material is spread in a uniform thin layer on a support (plate) of glass, metal or plastic. Solutions of analytes are deposited on the plate prior to development. The separation is based on adsorption, partition, ion-exchange or on combinations of these mechanisms and is carried out by migration (development) of solutes (solutions of analytes) in a solvent or a suitable mixture of solvents (mobile phase) through the thin-layer (stationary phase).

APPARATUS

Plates. The chromatography is carried out using pre-coated plates as described under *Reagents* (*4.1.1*).

Pre-treatment of the plates. It may be necessary to wash the plates prior to separation. This can be done by migration of an appropriate solvent. The plates may also be impregnated by procedures such as development, immersion or spraying. At the time of use, the plates may be activated, if necessary, by heating in an oven at 120 °C for 20 min.

Chromatographic tank with a flat bottom or twin trough, of inert, transparent material, of a size suitable for the plates used and provided with a tightly fitting lid. For horizontal development the tank is provided with a trough for the mobile phase and it additionally contains a device for directing the mobile phase to the stationary phase.

Micropipettes, microsyringes, calibrated disposable capillaries or other application devices suitable for the proper application of the solutions.

Fluorescence detection device to measure direct fluorescence or the inhibition of fluorescence.

Visualisation devices and reagents. Suitable devices are used for derivatisation to transfer to the plate reagents by spraying, immersion or exposure to vapour and, where applicable, to facilitate heating for visualisation of separated components.

Documentation. A device may be used to provide documentation of the visualised chromatogram, for example a photograph or a computer file.

METHOD

Sample application. Apply the prescribed volume of the solutions at a suitable distance from the lower edge and from the sides of the plate and on a line parallel to the lower edge; allow an interval of at least 10 mm (5 mm on high-performance plates) between the centres of circular spots and 5 mm (2 mm on high-performance plates) between the edges of bands. Apply the solutions in sufficiently small portions to obtain circular spots 2-5 mm in diameter (1-2 mm on high-performance plates) or bands 10-20 mm (5-10 mm on high-performance plates) by 1-2 mm.

In a monograph, where both normal and high-performance plates may be used, the working conditions for high-performance plates are given in the brackets [ ] after those for normal plates.

Vertical development. Line the walls of the chromatographic tank with filter paper. Pour into the chromatographic tank a sufficient quantity of the mobile phase for the size of the tank to give after impregnation of the filter paper a layer of appropriate depth related to the dimension of the plate to be used. For saturation of the chromatographic tank, replace the lid and allow to stand at 20-25 °C for 1 h. Unless otherwise indicated in the monograph, the chromatographic separation is performed in a saturated tank. Apply the prescribed volume of solutions as described above. When the solvent has evaporated from the applied solutions, place the plate in the chromatographic tank, ensuring that the plate is as vertical as possible and that the spots or bands are above the surface of the mobile phase. Close the chromatographic tank, maintain it at 20-25 °C and protect from sunlight. Remove the plate when the mobile phase has moved over the prescribed distance, measured between the points of application and the solvent front. Dry the plate and visualise the chromatograms as prescribed.

For two-dimensional chromatography, dry the plates after the first development and carry out a second development in a direction perpendicular to that of the first development.

Horizontal development. Apply the prescribed volume of the solutions as described above. When the solvent has evaporated from the applied solutions, introduce a sufficient quantity of the mobile phase into the trough of the chamber using a syringe or pipette, place the plate in the chamber after verifying that the latter is horizontal and connect the mobile phase direction device according to the manufacturer's instructions. If prescribed, develop the plate starting simultaneously at both ends. Close the chamber and maintain it at 20-25 °C. Remove the plate when the mobile phase has moved over the distance prescribed in the monograph. Dry the plate and visualise the chromatograms as prescribed.

For two-dimensional chromatography, dry the plates after the first development and carry out a second development in a direction perpendicular to that of the first development.

VISUAL EVALUATION

Identification. The principal spot in the chromatogram obtained with the test solution is visually compared to the corresponding spot in the chromatogram obtained with the reference solution by comparing the colour, the size and the retardation factor (R_F) of both spots.

The retardation factor (R_F) is defined as the ratio of the distance from the point of application to the centre of the spot and the distance travelled by the solvent front from the point of application.

Verification of the separating power for identification. Normally the performance given by the suitability test described in *Reagents* (*4.1.1*) is sufficient. Only in special cases an additional performance criterion is prescribed in the monograph.

Related substances test. The secondary spot(s) in the chromatogram obtained with the test solution is (are) visually compared to either the corresponding spot(s) in the chromatogram obtained with the reference solution containing the impurity(ies) or the spot in the chromatogram obtained with the reference solution prepared from a dilution of the test solution.

Verification of the separating power. The requirements for the verification of the separating power are prescribed in the monographs concerned.

Verification of the detecting power. The detecting power is satisfactory if a spot or band is clearly visible in the chromatogram obtained with the most dilute reference solution.

QUANTITATIVE MEASUREMENT

The requirements for resolution and separation are prescribed in the monographs concerned.

Substances separated by thin-layer chromatography and responding to UV-Vis irradiation can be determined directly on the plate, using appropriate instrumentation. While moving the plate or the measuring device, examine the plate by measuring the reflectance of the incident light. Similarly, fluorescence may be measured using an appropriate optical system. Substances containing radionuclides can be quantified in 3 ways: either directly by moving the plate alongside a suitable counter or vice versa (see *Radiopharmaceutical preparations (0125)*), by cutting the plates into strips and measuring the radioactivity on each individual strip using a suitable counter or by scraping off the stationary phase, dissolving it in a suitable scintillation cocktail and measuring the radioactivity using a liquid scintillation counter.

Apparatus. The apparatus for direct measurement on the plate consists of:

- a device for exact positioning and reproducible dispensing of the amount of substances onto the plate;
- a mechanical device to move the plate or the measuring device along the *x*-axis or the *y*-axis;
- a recorder and a suitable integrator or a computer;
- *for substances responding to UV-Vis irradiation*: a photometer with a source of light, an optical device able to generate monochromatic light and a photo cell of adequate sensitivity are used for the measurement of reflectance or transmittance; if fluorescence is measured, a suitable filter is required to prevent light used for excitation from reaching the detector while permitting emitted light or a specific portion thereof to pass;
- *for substances containing radionuclides*: a suitable counter for radioactivity. The linearity range of the counting device is to be verified.

Method. Prepare the solution of the substance to be examined (test solution) as prescribed in the monograph and, if necessary, prepare the reference solutions of the substance to be determined using the same solvent as in the test solution. Apply the same volume of each solution to the plate and develop.

Substances responding to UV-Vis irradiation. Prepare and apply not fewer than 3 reference solutions of the substance to be examined, the concentrations of which span the expected value in the test solution (about 80 per cent, 100 per cent

and 120 per cent). Treat with the prescribed reagent, if necessary, and record the reflectance, the transmittance or fluorescence in the chromatograms obtained with the test and reference solutions. Use the measured results for the calculation of the amount of substance in the test solution.

Substances containing radionuclides. Prepare and apply a test solution containing about 100 per cent of the expected value. Determine the radioactivity as a function of the path length and report the radioactivity in each resulting peak as a percentage of the total amount of radioactivity.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (*2.2.46*). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

01/2008:20228

2.2.28. GAS CHROMATOGRAPHY

Gas chromatography (GC) is a chromatographic separation technique based on the difference in the distribution of species between two non-miscible phases in which the mobile phase is a carrier gas moving through or passing the stationary phase contained in a column. It is applicable to substances or their derivatives which are volatilised under the temperatures employed.

GC is based on mechanisms of adsorption, mass distribution or size exclusion.

APPARATUS

The apparatus consists of an injector, a chromatographic column contained in an oven, a detector and a data acquisition system (or an integrator or a chart recorder). The carrier gas flows through the column at a controlled rate or pressure and then through the detector.

The chromatography is carried out either at a constant temperature or according to a given temperature programme.

INJECTORS

Direct injections of solutions are the usual mode of injection, unless otherwise prescribed in the monograph. Injection may be carried out either directly at the head of the column using a syringe or an injection valve, or into a vaporisation chamber which may be equipped with a stream splitter.

Injections of vapour phase may be effected by static or dynamic head-space injection systems.

Dynamic head-space (purge and trap) injection systems include a sparging device by which volatile substances in solution are swept into an absorbent column maintained at a low temperature. Retained substances are then desorbed into the mobile phase by rapid heating of the absorbent column.

Static head-space injection systems include a thermostatically controlled sample heating chamber in which closed vials containing solid or liquid samples are placed for a fixed period of time to allow the volatile components of the sample to reach equilibrium between the non-gaseous phase and the vapour phase. After equilibrium has been established, a predetermined amount of the head-space of the vial is flushed into the gas chromatograph.

STATIONARY PHASES

Stationary phases are contained in columns which may be:

- a capillary column of fused-silica whose wall is coated with the stationary phase,
- a column packed with inert particles impregnated with the stationary phase,
- a column packed with solid stationary phase.

Capillary columns are 0.1 mm to 0.53 mm in internal diameter (Ø) and 5 m to 60 m in length. The liquid or stationary phase, which may be chemically bonded to the inner surface, is a film 0.1 µm to 5.0 µm thick.

Packed columns, made of glass or metal, are usually 1 m to 3 m in length with an internal diameter (Ø) of 2 mm to 4 mm. Stationary phases usually consist of porous polymers or solid supports impregnated with liquid phase.

Supports for analysis of polar compounds on columns packed with low-capacity, low-polarity stationary phase must be inert to avoid peak tailing. The reactivity of support materials can be reduced by silanising prior to coating with liquid phase. Acid-washed, flux-calcinated diatomaceous earth is often used. Materials are available in various particle sizes, the most commonly used particles are in the ranges of 150 µm to 180 µm and 125 µm to 150 µm.

MOBILE PHASES

Retention time and peak efficiency depend on the carrier gas flow rate; retention time is directly proportional to column length and resolution is proportional to the square root of the column length. For packed columns, the carrier gas flow rate is usually expressed in millilitres per minute at atmospheric pressure and room temperature. Flow rate is measured at the detector outlet, either with a calibrated mechanical device or with a bubble tube, while the column is at operating temperature. The linear velocity of the carrier gas through a packed column is inversely proportional to the square root of the internal diameter of the column for a given flow volume. Flow rates of 60 ml/min in a 4 mm internal diameter column and 15 ml/min in a 2 mm internal diameter column, give identical linear velocities and thus similar retention times.

Helium or nitrogen are usually employed as the carrier gas for packed columns, whereas commonly used carrier gases for capillary columns are nitrogen, helium and hydrogen.

DETECTORS

Flame-ionisation detectors are usually employed but additional detectors which may be used include: electron-capture, nitrogen-phosphorus, mass spectrometric, thermal conductivity, Fourier transform infrared spectrophotometric, and others, depending on the purpose of the analysis.

METHOD

Equilibrate the column, the injector and the detector at the temperatures and the gas flow rates specified in the monograph until a stable baseline is achieved. Prepare the test solution(s) and the reference solution(s) as prescribed. The solutions must be free from solid particles.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (*2.2.46*). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

Static head-space gas chromatography

Static head-space gas chromatography is a technique particularly suitable for separating and determining volatile compounds present in solid or liquid samples. The method is based on the analysis of the vapour phase in equilibrium with the solid or liquid phase.

APPARATUS

The apparatus consists of a gas chromatograph provided with a device for introducing the sample that may be connected to a module that automatically controls the pressure and the temperature. If necessary, a device for eliminating solvents can be added.

The sample to be analysed is introduced into a container fitted with a suitable stopper and a valve-system which permits the passage of the carrier gas. The container is placed in a thermostatically controlled chamber at a temperature set according to the substance to be examined.

The sample is held at this temperature long enough to allow equilibrium to be established between the solid or liquid phase and the vapour phase.

The carrier gas is introduced into the container and, after the prescribed time, a suitable valve is opened so that the gas expands towards the chromatographic column taking the volatilised compounds with it.

Instead of using a chromatograph specifically equipped for the introduction of samples, it is also possible to use airtight syringes and a conventional chromatograph. Equilibration is then carried out in a separate chamber and the vapour phase is carried onto the column, taking the precautions necessary to avoid any changes in the equilibrium.

METHOD

Using the reference preparations, determine suitable instrument settings to produce an adequate response.

DIRECT CALIBRATION

Separately introduce into identical containers the preparation to be examined and each of the reference preparations, as prescribed in the monograph, avoiding contact between the sampling device and the samples.

Close the containers hermetically and place in the thermostatically controlled chamber set to the temperature and pressure prescribed in the monograph; after equilibration, carry out the chromatography under the prescribed conditions.

STANDARD ADDITIONS

Add to a set of identical suitable containers equal volumes of the preparation to be examined. Add to all but one of the containers, suitable quantities of a reference preparation containing a known concentration of the substance to be determined so as to produce a series of preparations containing steadily increasing concentrations of the substance.

Close the containers hermetically and place in the thermostatically controlled chamber set to the temperature and pressure prescribed in the monograph; after equilibration, carry out the chromatography under the prescribed conditions.

Calculate the linear equation of the graph using a least-squares fit, and derive from it the concentration of the substance to be determined in the preparation to be examined.

Alternatively, plot on a graph the mean of readings against the added quantity of the substance to be determined. Extrapolate the line joining the points on the graph until it meets the concentration axis. The distance between this point and the intersection of the axes represents the concentration of the substance to be determined in the preparation to be examined.

SUCCESSIVE WITHDRAWALS (MULTIPLE HEAD-SPACE EXTRACTION)

If prescribed, the successive withdrawal method is fully described in the monograph.

01/2008:20229

2.2.29. LIQUID CHROMATOGRAPHY

Liquid chromatography (LC) is a method of chromatographic separation based on the difference in the distribution of species between two non-miscible phases, in which the mobile phase is a liquid which percolates through a stationary phase contained in a column.

LC is mainly based on mechanisms of adsorption, mass distribution, ion exchange, size exclusion or stereochemical interaction.

APPARATUS

The apparatus consists of a pumping system, an injector, a chromatographic column (a column temperature controller may be used), a detector and a data acquisition system (or an integrator or a chart recorder). The mobile phase is supplied from one or several reservoirs and flows through the column, usually at a constant rate, and then through the detector.

PUMPING SYSTEMS

LC pumping systems are required to deliver the mobile phase at a constant flow rate. Pressure fluctuations are to be minimised, e.g. by passing the pressurised solvent through a pulse-dampening device. Tubing and connections are capable of withstanding the pressures developed by the pumping system. LC pumps may be fitted with a facility for "bleeding" the system of entrapped air bubbles.

Microprocessor controlled systems are capable of accurately delivering a mobile phase of either constant (isocratic elution) or varying composition (gradient elution), according to a defined programme. In the case of gradient elution, pumping systems which deliver solvent(s) from several reservoirs are available and solvent mixing can be achieved on either the low or high-pressure side of the pump(s).

INJECTORS

The sample solution is introduced into the flowing mobile phase at or near the head of the column using an injection system which can operate at high pressure. Fixed-loop and variable volume devices operated manually or by an auto-sampler are used. Manual partial filling of loops may lead to poorer injection volume precision.

STATIONARY PHASES

There are many types of stationary phases employed in LC, including:

- silica, alumina or porous graphite, used in normal-phase chromatography, where the separation is based on differences in adsorption and/or mass distribution,
- resins or polymers with acid or basic groups, used in ion-exchange chromatography, where separation is based on competition between the ions to be separated and those in the mobile phase,
- porous silica or polymers, used in size-exclusion chromatography, where separation is based on differences between the volumes of the molecules, corresponding to steric exclusion,

– a variety of chemically modified supports prepared from polymers, silica or porous graphite, used in reversed-phase LC, where the separation is based principally on partition of the molecules between the mobile phase and the stationary phase,

– special chemically modified stationary phases, e.g. cellulose or amylose derivatives, proteins or peptides, cyclodextrins etc., for the separation of enantiomers (chiral chromatography).

Most separations are based upon partition mechanisms utilising chemically modified silica as the stationary phase and polar solvents as the mobile phase. The surface of the support, e.g. the silanol groups of silica, is reacted with various silane reagents to produce covalently bound silyl derivatives covering a varying number of active sites on the surface of the support. The nature of the bonded phase is an important parameter for determining the separation properties of the chromatographic system.

Commonly used bonded phases are shown below:

octyl	= Si-$[CH_2]_7$-CH_3	C_8
octadecyl	= Si-$[CH_2]_{17}$-CH_3	C_{18}
phenyl	= Si-$[CH_2]_n$-C_6H_5	C_6H_5
cyanopropyl	= Si-$[CH_2]_3$-CN	CN
aminopropyl	= Si-$[CH_2]_3$-NH_2	NH_2
diol	= Si-$[CH_2]_3$-O-CH(OH)-CH_2-OH	

Unless otherwise stated by the manufacturer, silica based reversed-phase columns are considered to be stable in mobile phases having an apparent pH in the range 2.0 to 8.0. Columns containing porous graphite or particles of polymeric materials such as styrene-divinylbenzene copolymer are stable over a wider pH range.

Analysis using normal-phase chromatography with unmodified silica, porous graphite or polar chemically modified silica, e.g. cyanopropyl or diol, as the stationary phase with a non-polar mobile phase is applicable in certain cases.

For analytical separations, the particle size of the most commonly used stationary phases varies between 3 µm and 10 µm. The particles may be spherical or irregular, of varying porosity and specific surface area. These parameters contribute to the chromatographic behaviour of a particular stationary phase. In the case of reversed phases, the nature of the stationary phase, the extent of bonding, e.g. expressed as the carbon loading, and whether the stationary phase is end-capped (i.e. residual silanol groups are silylated) are additional determining factors. Tailing of peaks, particularly of basic substances, can occur when residual silanol groups are present.

Columns, made of stainless steel unless otherwise prescribed in the monograph, of varying length and internal diameter (Ø) are used for analytical chromatography. Columns with internal diameters of less than 2 mm are often referred to as microbore columns. The temperature of the mobile phase and the column must be kept constant during an analysis. Most separations are performed at room temperature, but columns may be heated to give higher efficiency. It is recommended that columns not be heated above 60 °C because of the potential for stationary phase degradation or changes occurring to the composition of the mobile phase.

MOBILE PHASES

For normal-phase chromatography, less polar solvents are employed. The presence of water in the mobile phase is to be strictly controlled to obtain reproducible results. In reversed-phase LC, aqueous mobile phases, with or without organic modifiers, are employed.

Components of the mobile phase are usually filtered to remove particles greater than 0.45 µm. Multicomponent mobile phases are prepared by measuring the required volumes (unless masses are specified) of the individual components, followed by mixing. Alternatively, the solvents may be delivered by individual pumps controlled by proportioning valves by which mixing is performed according to the desired proportion. Solvents are normally degassed before pumping by sparging with helium, sonication or using on-line membrane/vacuum modules to avoid the creation of gas bubbles in the detector cell.

Solvents for the preparation of the mobile phase are normally free of stabilisers and are transparent at the wavelength of detection, if an ultraviolet detector is employed. Solvents and other components employed are to be of appropriate quality. Adjustment of the pH, if necessary, is effected using only the aqueous component of the mobile phase and not the mixture. If buffer solutions are used, adequate rinsing of the system is carried out with a mixture of water and the organic modifier of the mobile phase (5 per cent *V/V*) to prevent crystallisation of salts after completion of the chromatography.

Mobile phases may contain other components, e.g. a counter-ion for ion-pair chromatography or a chiral selector for chromatography using an achiral stationary phase.

DETECTORS

Ultraviolet/visible (UV/Vis) spectrophotometers, including diode array detectors, are the most commonly employed detectors. Fluorescence spectrophotometers, differential refractometers, electrochemical detectors, mass spectrometers, light scattering detectors, radioactivity detectors or other special detectors may also be used.

METHOD

Equilibrate the column with the prescribed mobile phase and flow rate, at room temperature or at the temperature specified in the monograph, until a stable baseline is achieved. Prepare the solution(s) of the substance to be examined and the reference solution(s) required. The solutions must be free from solid particles.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (*2.2.46*). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

01/2008:20230

2.2.30. SIZE-EXCLUSION CHROMATOGRAPHY

Size-exclusion chromatography is a chromatographic technique which separates molecules in solution according to their size. With organic mobile phases, the technique is known as *gel-permeation chromatography* and with aqueous mobile phases, the term *gel-filtration chromatography* has been used. The sample is introduced into a column, which is filled with a gel or a porous particle packing material, and is carried by the mobile phase through the column. The size separation takes place by repeated exchange of the solute

molecules between the solvent of the mobile phase and the same solvent in the stagnant liquid phase (stationary phase) within the pores of the packing material. The pore-size range of the packing material determines the molecular-size range within which separation can occur.

Molecules small enough to penetrate all the pore spaces elute at the *total permeation volume* (V_t). On the other hand, molecules apparently larger than the maximum pore size of the packing material migrate along the column only through the spaces between the particles of the packing material without being retained and elute at the *exclusion volume* (V_0 void volume). Separation according to molecular size occurs between the exclusion volume and the total permeation volume, with useful separation usually occurring in the first two thirds of this range.

Apparatus. The apparatus consists essentially of a chromatographic column of varying length and internal diameter (Ø), if necessary temperature-controlled, packed with a separation material that is capable of fractionation in the appropriate range of molecular sizes and through which the eluent is passed at a constant rate. One end of the column is usually fitted with a suitable device for applying the sample such as a flow adapter, a syringe through a septum or an injection valve and may also be connected to a suitable pump for controlling the flow of the eluent. Alternatively the sample may be applied directly to the drained bed surface or, where the sample is denser than the eluent, it may be layered beneath the eluent. The outlet of the column is usually connected to a suitable detector fitted with an automatic recorder which enables the monitoring of the relative concentrations of separated components of the sample. Detectors are usually based on photometric, refractometric or luminescent properties. An automatic fraction collector may be attached, if necessary.

The packing material may be a soft support such as a swollen gel or a rigid support composed of a material such as glass, silica or a solvent-compatible, cross-linked organic polymer. Rigid supports usually require pressurised systems giving faster separations. The mobile phase is chosen according to sample type, separation medium and method of detection. Before carrying out the separation, the packing material is treated, and the column is packed, as described in the monograph, or according to the manufacturer's instructions.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (*2.2.46*). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

DETERMINATION OF RELATIVE COMPONENT COMPOSITION OF MIXTURES

Carry out the separation as stated in the monograph. If possible, monitor the elution of the components continuously and measure the corresponding peak areas. If the sample is monitored by a physico-chemical property to which all the components of interest exhibit equivalent responses (for example if they have the same specific absorbance), calculate the relative amount of each component by dividing the respective peak area by the sum of the peak areas of all the components of interest. If the responses to the property used for detection of the components of interest are not equivalent, calculate the content by means of calibration curves obtained with the calibration standards prescribed in the monograph.

DETERMINATION OF MOLECULAR MASSES

Size-exclusion chromatography may be used to determine molecular masses by comparison with appropriate calibration standards specified in the monograph. The retention volumes of the calibration standards may be plotted against the logarithm of their molecular masses. The plot usually approximates a straight line within the exclusion and total permeation limits for the separation medium used. From the calibration curve, molecular masses may be estimated. The molecular-mass calibration is valid only for the particular macromolecular solute/solvent system used under the specified experimental conditions.

DETERMINATION OF MOLECULAR SIZE DISTRIBUTION OF POLYMERS

Size-exclusion chromatography may be used to determine the distribution of the molecular size of polymers. However, sample comparison may be valid only for results obtained under the same experimental conditions. The reference substances used for the calibration and the methods for determination of the distribution of molecular sizes of polymers are specified in the monograph.

01/2008:20231

2.2.31. ELECTROPHORESIS

GENERAL PRINCIPLE

Under the influence of an electrical field, charged particles dissolved or dispersed in an electrolyte solution migrate in the direction of the electrode bearing the opposite polarity. In gel electrophoresis, the movements of the particles are retarded by interactions with the surrounding gel matrix, which acts as a molecular sieve. The opposing interactions of the electrical force and molecular sieving result in differential migration rates according to sizes, shapes and charges of particles. Because of their different physico-chemical properties, different macromolecules of a mixture will migrate at different speeds during electrophoresis and will thus be separated into discrete fractions. Electrophoretic separations can be conducted in systems without support phases (e.g. free solution separation in capillary electrophoresis) and in stabilising media such as thin-layer plates, films or gels.

FREE OR MOVING BOUNDARY ELECTROPHORESIS

This method is mainly used for the determination of mobility, the experimental characteristics being directly measurable and reproducible. It is chiefly employed with substances of high relative molecular mass and low diffusibility. The boundaries are initially located by a physical process such as refractometry or conductimetry. After applying a given electric field for an accurately measured time, the new boundaries and their respective positions are observed. The operating conditions must be such as to make it possible to determine as many boundaries as there are components.

ZONE ELECTROPHORESIS USING A SUPPORTING MEDIUM

This method requires the use of small samples only.

The nature of the support, such as paper, agar gel, cellulose acetate, starch, agarose, methacrylamide, mixed gel, introduces a number of additional factors modifying the mobility:

a) owing to channelling in the supporting medium, the apparent distance covered is less than the real distance,

b) some supporting media are not electrically neutral. As the medium is a stationary phase it may sometimes give rise to a considerable electro-endosmotic flow,

c) any heating due to the joule effect may cause some evaporation of the liquid from the supporting medium which, by capillarity, causes the solution to move from the ends towards the centre. The ionic strength therefore tends to increase gradually.

The rate of migration then depends on four main factors: the mobility of the charged particle, the electro-endosmotic flow, the evaporation flow, and the field strength. Hence it is necessary to operate under clearly defined experimental conditions and to use, wherever possible, reference substances.

An *apparatus* for electrophoresis consists of:

– a *generator supplying direct current* whose voltage can be controlled and, preferably, stabilised,

– an *electrophoresis chamber*. This is usually rectangular and made of glass or rigid plastic, with two separate compartments, the anodic and the cathodic, containing the electrolyte solution. In each compartment is immersed an electrode, for example of platinum or graphite. These are connected by means of an appropriately isolated circuit to the corresponding terminal of the power supply to form the anode and the cathode. The level of the liquid in the two compartments is kept equal to prevent siphoning.

  The electrophoresis chamber is fitted with an airtight lid which maintains a moisture-saturated atmosphere during operation and reduces evaporation of the solvent. A safety device may be used to cut off the power when the lid is removed. If the electrical power measured across the strip exceeds 10 W, it is preferable to cool the support.

– a *support-carrying device*:

  Strip electrophoresis. The supporting strip, previously wetted with the same conducting solution and dipped at each end into an electrode compartment is appropriately tightened and fixed on to a suitable carrier designed to prevent diffusion of the conducting electrolyte, such as a horizontal frame, inverted-V stand or a uniform surface with contact points at suitable intervals.

  Gel electrophoresis. The device consists essentially of a glass plate (for example, a microscope slide) over the whole surface of which is deposited a firmly adhering layer of gel of uniform thickness. The connection between the gel and the conducting solution is effected in various ways according to the type of apparatus used. Precautions must be taken to avoid condensation of moisture or drying of the solid layer.

– measuring *device or means of detection*.

Method. Introduce the electrolyte solution into the electrode compartments. Place the support suitably impregnated with electrolyte solution in the chamber under the conditions prescribed for the type of apparatus used. Locate the starting line and apply the sample. Apply the electric current for the prescribed time. After the current has been switched off, remove the support from the chamber, dry and visualise.

POLYACRYLAMIDE ROD GEL ELECTROPHORESIS

In polyacrylamide rod gel electrophoresis, the stationary phase is a gel which is prepared from a mixture of acrylamide and *N,N'*-methylenebisacrylamide. Rod gels are prepared in tubes 7.5 cm long and 0.5 cm in internal diameter, one solution being applied to each rod.

Apparatus. This consists of two buffer solution reservoirs made of suitable material such as poly(methyl methacrylate) and mounted vertically one above the other. Each reservoir is fitted with a platinum electrode. The electrodes are connected to a power supply allowing operation either at constant current or at constant voltage. The apparatus has in the base of the upper reservoir a number of holders equidistant from the electrode.

Method. The solutions should usually be degassed before polymerisation and the gels used immediately after preparation. Prepare the gel mixture as prescribed and pour into suitable glass tubes, stoppered at the bottom, to an equal height in each tube and to about 1 cm from the top, taking care to ensure that no air bubbles are trapped in the tubes. Cover the gel mixture with a layer of *water R* to exclude air and allow to set. Gel formation usually takes about 30 min and is complete when a sharp interface appears between the gel and the water layer. Remove the water layer. Fill the lower reservoir with the prescribed buffer solution and remove the stoppers from the tubes. Fit the tubes into the holders of the upper reservoir and adjust so that the bottom of the tubes are immersed in the buffer solution in the lower reservoir. Carefully fill the tubes with the prescribed buffer solution. Prepare the test and reference solutions containing the prescribed marker dye and make them dense by dissolving in them *sucrose R*, for example. Apply the solutions to the surface of a gel using a different tube for each solution. Add the same buffer to the upper reservoir. Connect the electrodes to the power supply and allow electrophoresis to proceed at the prescribed temperature and using the prescribed constant voltage or current. Switch off the power supply when the marker dye has migrated almost into the lower reservoir. Immediately remove each tube from the apparatus and extrude the gel. Locate the position of the bands in the electropherogram as prescribed.

SODIUM DODECYL SULPHATE POLYACRYLAMIDE GEL ELECTROPHORESIS (SDS-PAGE)

Scope. Polyacrylamide gel electrophoresis is used for the qualitative characterisation of proteins in biological preparations, for control of purity and quantitative determinations.

Purpose. Analytical gel electrophoresis is an appropriate method with which to identify and to assess the homogeneity of proteins in pharmaceutical preparations. The method is routinely used for the estimation of protein subunit molecular masses and for determining the subunit compositions of purified proteins.

Ready-to-use gels and reagents are widely available on the market and can be used instead of those described in this text, provided that they give equivalent results and that they meet the validity requirements given below under Validation of the test.

CHARACTERISTICS OF POLYACRYLAMIDE GELS

The sieving properties of polyacrylamide gels are established by the three-dimensional network of fibres and pores which is formed as the bifunctional bisacrylamide cross-links adjacent polyacrylamide chains. Polymerisation is catalysed by a free radical-generating system composed of ammonium persulphate and tetramethylethylenediamine.

As the acrylamide concentration of a gel increases, its effective pore size decreases. The effective pore size of a gel is operationally defined by its sieving properties; that is, by the resistance it imparts to the migration of macromolecules. There are limits on the acrylamide concentrations that can be used. At high acrylamide concentrations, gels break much more easily and are difficult to handle. As the pore size of a gel decreases, the migration rate of a protein through the gel decreases. By adjusting the pore size of a gel, through manipulating the acrylamide concentration, the resolution

of the method can be optimised for a given protein product. Thus, a given gel is physically characterised by its respective composition in acrylamide and bisacrylamide.

In addition to the composition of the gel, the state of the protein is an important component to the electrophoretic mobility. In the case of proteins, the electrophoretic mobility is dependent on the pK value of the charged groups and the size of the molecule. It is influenced by the type, concentration and pH of the buffer, by the temperature and the field strength as well as by the nature of the support material.

DENATURING POLYACRYLAMIDE GEL ELECTROPHORESIS

The method cited as an example is limited to the analysis of monomeric polypeptides with a mass range of 14 000 to 100 000 daltons. It is possible to extend this mass range by various techniques (e.g. gradient gels, particular buffer system) but those techniques are not discussed in this chapter.

Denaturing polyacrylamide gel electrophoresis using sodium dodecyl sulphate (SDS-PAGE) is the most common mode of electrophoresis used in assessing the pharmaceutical quality of protein products and will be the focus of the example method. Typically, analytical electrophoresis of proteins is carried out in polyacrylamide gels under conditions that ensure dissociation of the proteins into their individual polypeptide subunits and that minimise aggregation. Most commonly, the strongly anionic detergent sodium dodecyl sulphate (SDS) is used in combination with heat to dissociate the proteins before they are loaded on the gel. The denatured polypeptides bind to SDS, become negatively charged and exhibit a consistent charge-to-mass ratio regardless of protein type. Because the amount of SDS bound is almost always proportional to the molecular mass of the polypeptide and is independent of its sequence, SDS-polypeptide complexes migrate through polyacrylamide gels with mobilities dependent on the size of the polypeptide.

The electrophoretic mobilities of the resultant detergent-polypeptide complexes all assume the same functional relationship to their molecular masses. Migration of SDS complexes is toward the anode in a predictable manner, with low-molecular-mass complexes migrating faster than larger ones. The molecular mass of a protein can therefore be estimated from its relative mobility in calibrated SDS-PAGE and the occurrence of a single band in such a gel is a criterion of purity.

Modifications to the polypeptide backbone, such as *N*- or *O*-linked glycosylation, however, have a significant impact on the apparent molecular mass of a protein since SDS does not bind to a carbohydrate moiety in a manner similar to a polypeptide. Thus, a consistent charge-to-mass ratio is not maintained. The apparent molecular mass of proteins having undergone post-translational modifications is not a true reflection of the mass of the polypeptide chain.

Reducing conditions. Polypeptide subunits and three-dimensional structure is often maintained in proteins by the presence of disulphide bonds. A goal of SDS-PAGE analysis under reducing conditions is to disrupt this structure by reducing disulphide bonds. Complete denaturation and dissociation of proteins by treatment with 2-mercaptoethanol or dithiothreitol (DTT) will result in unfolding of the polypeptide backbone and subsequent complexation with SDS. In these conditions, the molecular mass of the polypeptide subunits can be calculated by linear regression in the presence of suitable molecular-mass standards.

Non-reducing conditions. For some analyses, complete dissociation of the protein into subunit peptides is not desirable. In the absence of treatment with reducing agents such as 2-mercaptoethanol or DTT, disulphide covalent bonds remain intact, preserving the oligomeric form of the protein. Oligomeric SDS-protein complexes migrate more slowly than their SDS-polypeptide subunits. In addition, non-reduced proteins may not be completely saturated with SDS and, hence, may not bind the detergent in a constant mass ratio. This makes molecular-mass determinations of these molecules by SDS-PAGE less straightforward than analyses of fully denatured polypeptides, since it is necessary that both standards and unknown proteins be in similar configurations for valid comparisons. However, the staining of a single band in such a gel is a criterion of purity.

CHARACTERISTICS OF DISCONTINUOUS BUFFER SYSTEM GEL ELECTROPHORESIS

The most popular electrophoretic method for the characterisation of complex mixtures of proteins involves the use of a discontinuous buffer system consisting of two contiguous, but distinct gels: a resolving or separating (lower) gel and a stacking (upper) gel. The two gels are cast with different porosities, pH, and ionic strengths. In addition, different mobile ions are used in the gel and electrode buffers. The buffer discontinuity acts to concentrate large volume samples in the stacking gel, resulting in improved resolution. When power is applied, a voltage drop develops across the sample solution which drives the proteins into the stacking gel. Glycinate ions from the electrode buffer follow the proteins into the stacking gel. A moving boundary region is rapidly formed with the highly mobile chloride ions in the front and the relatively slow glycinate ions in the rear. A localised high-voltage gradient forms between the leading and trailing ion fronts, causing the SDS-protein complexes to form into a thin zone (stack) and migrate between the chloride and glycinate phases. Within broad limits, regardless of the height of the applied sample, all SDS-proteins condense into a very narrow region and enter the resolving gel as a well-defined, thin zone of high protein density. The large-pore stacking gel does not retard the migration of most proteins and serves mainly as an anticonvective medium. At the interface of the stacking and resolving gels, the proteins experience a sharp increase in retardation due to the restrictive pore size of the resolving gel. Once in the resolving gel, proteins continue to be slowed by the sieving of the matrix. The glycinate ions overtake the proteins, which then move in a space of uniform pH formed by the tris(hydroxymethyl)aminomethane and glycine. Molecular sieving causes the SDS-polypeptide complexes to separate on the basis of their molecular masses.

PREPARING VERTICAL DISCONTINUOUS BUFFER SDS POLYACRYLAMIDE GELS

Assembling of the gel moulding cassette. Clean the two glass plates (size: e.g. 10 cm × 8 cm), the polytetrafluoroethylene comb, the two spacers and the silicone rubber tubing (diameter e.g. 0.6 mm × 35 cm) with mild detergent and rinse extensively with water. Dry all the items with a paper towel or tissue. Lubricate the spacers and the tubing with non-silicone grease. Apply the spacers along each of the two short sides of the glass plate 2 mm away from the edges and 2 mm away from the long side corresponding to the bottom of the gel. Begin to lay the tubing on the glass plate by using one spacer as a guide. Carefully twist the tubing at the bottom of the spacer and follow the long side of the glass plate. While holding the tubing with one finger along the long side twist again the tubing and lay it on the second short side of the glass plate, using the spacer as a guide. Place the second glass plate in perfect alignment and hold

the mould together by hand pressure. Apply two clamps on each of the two short sides of the mould. Carefully apply four clamps on the longer side of the gel mould thus forming the bottom of the gel mould. Verify that the tubing is running along the edge of the glass plates and has not been extruded while placing the clamps. The gel mould is now ready for pouring the gel.

Preparation of the gel. In a discontinuous buffer SDS polyacrylamide gel, it is recommended to pour the resolving gel, let the gel set, and then pour the stacking gel since the composition of the two gels in acrylamide-bisacrylamide, buffer and pH are different.

Preparation of the resolving gel. In a conical flask, prepare the appropriate volume of solution containing the desired concentration of acrylamide for the resolving gel, using the values given in Table 2.2.31.-1. Mix the components in the order shown. Where appropriate, before adding the ammonium persulphate solution and the tetramethylethylenediamine (TEMED), filter the solution if necessary under vacuum through a cellulose acetate membrane (pore diameter 0.45 µm); keep the solution under vacuum by swirling the filtration unit until no more bubbles are formed in the solution. Add appropriate amounts of ammonium persulphate solution and TEMED as indicated in Table 2.2.31.-1, swirl and pour immediately into the gap between the two glass plates of the mould. Leave sufficient space for the stacking gel (the length of the teeth of the comb plus 1 cm). Using a tapered glass pipette, carefully overlay the solution with water-saturated isobutanol. Leave the gel in a vertical position at room temperature to allow polymerisation.

Preparation of the stacking gel. After polymerisation is complete (about 30 min), pour off the isobutanol and wash the top of the gel several times with water to remove the isobutanol overlay and any unpolymerised acrylamide. Drain as much fluid as possible from the top of the gel, and then remove any remaining water with the edge of a paper towel.

In a conical flask, prepare the appropriate volume of solution containing the desired concentration of acrylamide, using the values given in Table 2.2.31.-2. Mix the components in the order shown. Where appropriate, before adding the ammonium persulphate solution and the TEMED, filter the solution if necessary under vacuum through a cellulose acetate membrane (pore diameter: 0.45 µm); keep the solution under vacuum by swirling the filtration unit until no more bubbles are formed in the solution. Add appropriate amounts of ammonium persulphate solution and TEMED as indicated in Table 2.2.31.-2, swirl and pour immediately into the gap between the two glass plates of the mould directly onto the surface of the polymerised resolving gel. Immediately insert a clean polytetrafluoroethylene comb into the stacking gel solution, being careful to avoid trapping air bubbles. Add more stacking gel solution to fill the spaces of the comb completely. Leave the gel in a vertical position and allow to polymerise at room temperature.

(1) *Acrylamide solution: 30 per cent acrylamide/bisacrylamide(29:1) solution R.*

(2) 1.5 M Tris (pH 8.8): *1.5 M tris-hydrochloride buffer solution pH 8.8 R.*

(3) 100 g/l SDS: a 100 g/l solution of *sodium dodecyl sulphate R.*

(4) 100 g/l APS: a 100 g/l solution of *ammonium persulphate R.* Ammonium persulphate provides the free radicals that drive polymerisation of acrylamide and bisacrylamide. Since ammonium persulphate solution decomposes slowly, fresh solutions must be prepared weekly.

(5) TEMED: *tetramethylethylenediamine R.*

Mounting the gel in the electrophoresis apparatus and electrophoretic separation. After polymerisation is complete (about 30 min), remove the polytetrafluoroethylene comb carefully. Rinse the wells immediately with water or with the *SDS-PAGE running buffer R* to remove any unpolymerised acrylamide. If necessary, straighten the teeth of the stacking gel with a blunt hypodermic needle attached to a syringe. Remove the clamps on one short side, carefully pull out the tubing and replace the clamps. Proceed similarly on the other short side. Remove the tubing from the bottom part of the gel. Mount the gel in the electrophoresis apparatus. Add the electrophoresis buffers to the top and bottom reservoirs. Remove any bubbles that become trapped at the bottom of the gel between the glass plates. This is best done with a bent hypodermic needle attached to a syringe. Never pre-run the gel before loading the samples, since this will destroy the discontinuity of the buffer systems. Before loading the sample carefully rinse the slot with *SDS-PAGE running buffer R*. Prepare the test and reference solutions in the recommended sample buffer and treat as specified in the individual monograph. Apply the appropriate volume of each solution to the stacking gel wells. Start the electrophoresis

Table 2.2.31.-2. – *Preparation of stacking gel*

using the conditions recommended by the manufacturer of the equipment. Manufacturers of SDS-PAGE equipment may provide gels of different surface area and thickness. Electrophoresis running time and current/voltage may need to vary as described by the manufacturer of the apparatus in order to achieve optimum separation. Check that the dye front is moving into the resolving gel. When the dye is reaching the bottom of the gel, stop the electrophoresis. Remove the gel assembly from the apparatus and separate the glass plates. Remove the spacers, cut off and discard the stacking gel and immediately proceed with staining.

DETECTION OF PROTEINS IN GELS

Coomassie staining is the most common protein staining method with a detection level of the order of 1 µg to 10 µg of protein per band. Silver staining is the most sensitive method for staining proteins in gels and a band containing 10 ng to 100 ng can be detected.

All of the steps in gel staining are done at room temperature with gentle shaking (e.g. on an orbital shaker platform) in any convenient container. Gloves must be worn when staining gels, since fingerprints will stain.

Coomassie staining. Immerse the gel in a large excess of *Coomassie staining solution R* and allow to stand for at least 1 h. Remove the staining solution.

Destain the gel with a large excess of *destaining solution R*. Change the destaining solution several times, until the stained protein bands are clearly distinguishable on a clear background. The more thoroughly the gel is destained, the smaller is the amount of protein that can be detected by the method. Destaining can be speeded up by including a few grams of anion-exchange resin or a small sponge in the *destaining solution R*.

NOTE: the acid-alcohol solutions used in this procedure do not completely fix proteins in the gel. This can lead to losses of some low-molecular-mass proteins during the staining and destaining of thin gels. Permanent fixation is obtainable by allowing the gel to stand in a mixture of 1 volume of trichloroacetic acid R, 4 volumes of methanol R and 5 volumes of water R for 1 h before it is immersed in the Coomassie staining solution R.

Silver staining. Immerse the gel in a large excess of *fixing solution R* and allow to stand for 1 h. Remove the fixing solution, add fresh fixing solution and incubate either for at least 1 h or overnight, if convenient. Discard the fixing solution and wash the gel in a large excess of *water R* for 1 h. Soak the gel for 15 min in a 1 per cent *V/V* solution of *glutaraldehyde R*. Wash the gel twice for 15 min in a large excess of *water R*. Soak the gel in fresh *silver nitrate reagent R* for 15 min, in darkness. Wash the gel three times for 5 min in a large excess of *water R*. Immerse the gel for about 1 min in *developer solution R* until satisfactory staining has been obtained. Stop the development by incubation in the *blocking solution R* for 15 min. Rinse the gel with *water R*.

DRYING OF STAINED SDS POLYACRYLAMIDE GELS

Depending on the staining method used, gels are treated in a slightly different way. For Coomassie staining, after the destaining step, allow the gel to stand in a 100 g/l solution of *glycerol R* for at least 2 h (overnight incubation is possible). For silver staining, add to the final rinsing a step of 5 min in a 20 g/l solution of *glycerol R*.

Immerse two sheets of porous cellulose film in *water R* and incubate for 5 min to 10 min. Place one of the sheets on a drying frame. Carefully lift the gel and place it on the cellulose film. Remove any trapped air bubbles and pour a few millilitres of *water R* around the edges of the gel. Place the second sheet on top and remove any trapped air bubbles. Complete the assembly of the drying frame. Place in an oven or leave at room temperature until dry.

MOLECULAR-MASS DETERMINATION

Molecular masses of proteins are determined by comparison of their mobilities with those of several marker proteins of known molecular weight. Mixtures of proteins with precisely known molecular masses blended for uniform staining are available for calibrating gels. They are obtainable in various molecular mass ranges. Concentrated stock solutions of proteins of known molecular mass are diluted in the appropriate sample buffer and loaded on the same gel as the protein sample to be studied.

Immediately after the gel has been run, the position of the bromophenol blue tracking dye is marked to identify the leading edge of the electrophoretic ion front. This can be done by cutting notches in the edges of the gel or by inserting a needle soaked in India ink into the gel at the dye front. After staining, measure the migration distances of each protein band (markers and unknowns) from the top of the resolving gel. Divide the migration distance of each protein by the distance travelled by the tracking dye. The normalised migration distances so obtained are called the relative mobilities of the proteins (relative to the dye front) and conventionally denoted as R_F. Construct a plot of the logarithm of the relative molecular masses (M_r) of the protein standards as a function of the R_F values. Note that the graphs are slightly sigmoid. Unknown molecular masses can be estimated by linear regression analysis or interpolation from the curves of log M_r against R_F as long as the values obtained for the unknown samples are positioned along the linear part of the graph.

VALIDATION OF THE TEST

The test is not valid unless the proteins of the molecular mass marker are distributed along 80 per cent of the length of the gel and over the required separation range (e.g. the range covering the product and its dimer or the product and its related impurities) the separation obtained for the relevant protein bands shows a linear relationship between the logarithm of the molecular mass and the R_F. Additional validation requirements with respect to the solution under test may be specified in individual monographs.

QUANTIFICATION OF IMPURITIES

Where the impurity limit is specified in the individual monograph, a reference solution corresponding to that level of impurity should be prepared by diluting the test solution. For example, where the limit is 5 per cent, a reference solution would be a 1:20 dilution of the test solution. No impurity (any band other than the main band) in the electropherogram obtained with the test solution may be more intense than the main band obtained with the reference solution.

Under validated conditions impurities may be quantified by normalisation to the main band using an integrating densitometer. In this case, the responses must be validated for linearity.

01/2008:20232

2.2.32. LOSS ON DRYING

Loss on drying is the loss of mass expressed as per cent *m/m*.

Method. Place the prescribed quantity of the substance to be examined in a weighing bottle previously dried under the conditions prescribed for the substance to be examined. Dry the substance to constant mass or for the prescribed time by one of the following procedures. Where the drying

temperature is indicated by a single value rather than a range, drying is carried out at the prescribed temperature ± 2 °C.

a) "in a desiccator": the drying is carried out over *diphosphorus pentoxide R* at atmospheric pressure and at room temperature;

b) "*in vacuo*": the drying is carried out over *diphosphorus pentoxide R*, at a pressure of 1.5 kPa to 2.5 kPa at room temperature;

c) "*in vacuo* within a specified temperature range": the drying is carried out over *diphosphorus pentoxide R*, at a pressure of 1.5 kPa to 2.5 kPa within the temperature range prescribed in the monograph;

d) "in an oven within a specified temperature range": the drying is carried out in an oven within the temperature range prescribed in the monograph;

e) "under high vacuum": the drying is carried out over *diphosphorus pentoxide R* at a pressure not exceeding 0.1 kPa, at the temperature prescribed in the monograph.

If other conditions are prescribed, the procedure to be used is described in full in the monograph.

01/2008:20233

2.2.33. NUCLEAR MAGNETIC RESONANCE SPECTROMETRY

Nuclear magnetic resonance (NMR) spectrometry is based on the fact that nuclei such as ^{1}H, ^{13}C, ^{19}F, ^{31}P possess a permanent nuclear magnetic moment. When placed in an external magnetic field (main field), they take certain well-defined orientations with respect to the direction of this field which correspond to distinct energy levels. For a given field value, transitions between neighbouring energy levels take place due to absorption of electromagnetic radiation of characteristic wavelengths at radio frequencies.

The determination of these frequencies may be made either by sequential search of the resonance conditions (continuous-wave spectrometry) or by simultaneous excitation of all transitions with a multifrequency pulse followed by computer analysis of the free-induction decay of the irradiation emitted as the system returns to the initial state (pulsed spectrometry).

A *proton* magnetic resonance spectrum appears as a set of signals which correspond to protons and are characteristic of their nuclear and electronic environment within the molecule. The separation between a given signal and that of a reference compound is called a chemical shift (δ) and is expressed in parts per million (ppm); it characterises the kind of proton in terms of electronic environment. Signals are frequently split into groups of related peaks, called doublets, triplets, multiplets; this splitting is due to the presence of permanent magnetic fields emanating from adjacent nuclei, particularly from other protons within two to five valence bonds. The intensity of each signal, determined from the area under the signal, is proportional to the number of equivalent protons.

Apparatus. A nuclear magnetic resonance spectrometer for continuous-wave spectrometry consists of a magnet, a low-frequency sweep generator, a sample holder, a radio-frequency transmitter and receiver, a recorder and an electronic integrator. A pulsed spectrometer is additionally equipped with a pulse transmitter and a computer for the acquisition, storage and mathematical transformation of the data into a conventional spectrum.

Use a nuclear magnetic resonance spectrometer operating at not less than 60 MHz for ^{1}H. Unless otherwise prescribed, follow the instructions of the manufacturer.

Before recording the spectrum, verify that:

1) The resolution is equal to 0.5 Hz or less by measuring the peak width at half-height using an adequate scale expansion of:

– either the band at δ 7.33 ppm or at δ 7.51 ppm of the symmetrical multiplet of a 20 per cent *V/V* solution of *dichlorobenzene R* in *deuterated acetone R*,

– or the band at δ 0.00 ppm of a 5 per cent *V/V* solution of *tetramethylsilane R* in *deuterated chloroform R*.

2) The signal-to-noise ratio (*S/N*), measured over the range from δ 2 ppm to δ 5 ppm on the spectrum obtained with a 1 per cent *V/V* solution of *ethylbenzene R* in *deuterated chloroform R*, is at least 25:1. This ratio is calculated as the mean of five successive determinations from the expression:

$$\frac{S}{N} = 2.5\frac{A}{H}$$

A = amplitude, measured in millimetres, of the largest peak of the methylene quartet of ethylbenzene centred at δ 2.65 ppm. The amplitude is measured from a base line constructed from the centre of the noise on either side of this quartet and at a distance of at least 1 ppm from its centre.

H = peak to peak amplitude of the base line noise measured in millimetres obtained between δ 4 ppm and δ 5 ppm.

3) The amplitude of spinning side bands is not greater than 2 per cent of the sample peak height in a tube rotating at a speed appropriate for the spectrometer used.

4) For quantitative measurements verify the repeatability of the integrator responses, using a 5 per cent *V/V* solution of *ethylbenzene R* in *deuterated chloroform R*. Carry out five successive scans of the protons of ethyl groups and determine the mean of the values obtained. None of the individual values differs by more than 2.5 per cent from the mean.

Method. Dissolve the substance to be examined as prescribed and filter; the solution must be clear. Use a chemical shift internal reference compound, which, unless otherwise prescribed, is a solution containing 0.5 per cent *V/V* to 1.0 per cent *V/V* of *tetramethylsilane R* (TMS) in deuterated organic solvents or 5 g/l to 10 g/l of *sodium tetradeuteriodimethylsilapentanoate acid R* (TSP) in *deuterium oxide R*. Take the necessary quantity and record the spectrum.

CONTINUOUS-WAVE SPECTROMETRY

Adjust the spectrometer so that it is operating as closely as possible in the pure absorption mode and use a radio-frequency setting which avoids saturation of the signals. Adjust the controls of the spectrometer so that the strongest peak in the spectrum of the substance to be examined occupies almost the whole of the scale on the recorder chart and that the signal of the internal reference compound corresponds to a chemical shift of δ 0.00 ppm. Record the spectrum over the prescribed spectral width and, unless otherwise specified, at a sweep rate of not more than 2 Hz per second. Record the integral spectrum over the same spectral width and at a suitable sweep rate according to the instrument used. When quantitative measurements are required, these should be obtained as prescribed.

PULSED SPECTROMETRY

Set the spectrometer controls, e.g. pulse flip angle, pulse amplitude, pulse interval, spectral width, number of data points (resolution) and data acquisition rate, as indicated in the manufacturer's instructions and collect the necessary number of free induction decays. After mathematical transformation of the data by the computer, adjust the phase control in order to obtain as far as possible a pure absorption spectrum and calibrate the spectrum relative to the resonance frequency of the chemical shift internal reference compound. Display the spectrum stored in the computer on a suitable output device and, for quantitative measurements, process the integral according to the facility of the instrument.

01/2008:20234

2.2.34. THERMAL ANALYSIS

Thermal analysis is a group of techniques in which the variation of a physical property of a substance is measured as a function of temperature. The most commonly used techniques are those which measure changes of mass or changes in energy of a sample of a substance.

THERMOGRAVIMETRY

Thermogravimetry is a technique in which the mass of a sample of a substance is recorded as a function of temperature according to a controlled temperature programme.

Apparatus. The essential components of a thermobalance are a device for heating or cooling the substance according to a given temperature program, a sample holder in a controlled atmosphere, an electrobalance and a recorder. In some cases the instrument may be coupled to a device permitting the analysis of volatile products.

Temperature verification. Check the temperature scale using a suitable material according to the manufacturer's instructions.

Calibration of the electrobalance. Place a suitable quantity of a suitable certified reference material in the sample holder and record the mass. Set the heating rate according to the manufacturer's instructions and start the temperature increase. Record the thermogravimetric curve as a graph with temperature, or time, on the abscissa, increasing from left to right, and mass on the ordinate, increasing upwards. Stop the temperature increase at about 230 °C. Measure the difference on the graph between the initial and final mass-temperature plateaux, or mass-time plateaux, which corresponds to the loss of mass. The declared loss of mass for the certified reference material is stated on the label.

Method. Apply the same procedure to the substance to be examined, using the conditions prescribed in the monograph. Calculate the loss of mass of the substance to be examined from the difference measured in the graph obtained. Express the loss of mass as per cent $\Delta m/m$.

If the apparatus is in frequent use, carry out temperature verification and calibration regularly. Otherwise, carry out such checks before each measurement.

Since the test atmosphere is critical, the following parameters are noted for each measurement: pressure or flow rate, composition of the gas.

DIFFERENTIAL SCANNING CALORIMETRY

Differential Scanning Calorimetry (DSC) is a technique that can be used to demonstrate the energy phenomena produced during heating (or cooling) of a substance (or a mixture of substances) and to determine the changes in enthalpy and specific heat and the temperatures at which these occur.

The technique is used to determine the difference in the flow of heat (with reference to the temperature) evolved or absorbed by the test sample compared with the reference cell, as a function of the temperature. Two types of DSC apparatuses are available, those using power compensation to maintain a null temperature difference between sample and reference and those that apply a constant rate of heating and detect temperature differential as a difference in heat flow between sample and reference.

Apparatus. The apparatus for the power compensation DSC consists of a furnace containing a sample holder with a reference cell and a test cell. The apparatus for the heat flow DSC consists of a furnace containing a single cell with a sample holder for the reference crucible and the test crucible.

A temperature-programming device, thermal detector(s) and a recording system which can be connected to a computer are attached. The measurements are carried out under a controlled atmosphere.

Calibration of the apparatus. Calibrate the apparatus for temperature and enthalpy change, using indium of high purity or any other suitable certified material, according to the manufacturer's instructions. A combination of 2 metals, e.g. indium and zinc may be used to control linearity.

Operating procedure. Weigh in a suitable crucible an appropriate quantity of the substance to be examined; place it in the sample holder. Set the initial and final temperatures, and the heating rate according to the operating conditions prescribed in the monograph.

Begin the analysis and record the differential thermal analysis curve, with the temperature or time on the abscissa (values increasing from left to right) and the energy change on the ordinate (specify whether the change is endothermic or exothermic).

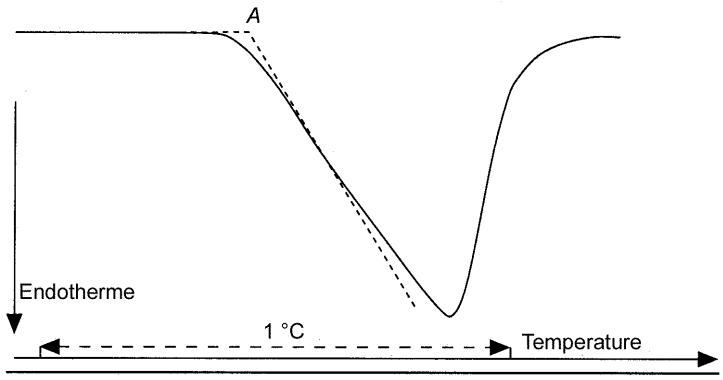

Figure 2.2.34.-1. – *Thermogram*

The temperature at which the phenomenon occurs (the onset temperature) corresponds to the intersection (A) of the extension of the baseline with the tangent at the point of greatest slope (inflexion point) of the curve (see Figure 2.2.34.-1). The end of the thermal phenomenon is indicated by the peak of the curve.

The enthalpy of the phenomenon is proportional to the area under the curve limited by the baseline; the proportionality factor is determined from the measurement of the heat of fusion of a known substance (e.g., indium) under the same operating conditions.

Each thermogram may be accompanied by the following data: conditions employed, record of last calibration, sample size and identification (including thermal history), container, atmosphere (identity, flow rate, pressure), direction and rate of temperature change, instrument and recorder sensitivity.

Applications

Phase changes. Determination of the temperature, heat capacity change and enthalpy of phase changes undergone by a substance as a function of temperature.

solid - solid transition:	allotropy - polymorphism glass transition desolvation amorphous-crystalline
solid - liquid transition:	melting
solid - gas transition:	sublimation
liquid - solid transition:	freezing recrystallisation
liquid - gas transition:	evaporation

Changes in chemical composition. Measurement of heat and temperatures of reaction under given experimental conditions, so that, for example, the kinetics of decomposition or of desolvation can be determined.

Application to phase diagrams. Establishment of phase diagrams for solid mixtures. The establishment of a phase diagram may be an important step in the preformulation and optimisation of the freeze-drying process.

Determination of purity. The measurement of the heat of fusion and the melting point by DSC enables the impurity content of a substance to be determined from a single thermal diagram, requiring the use of only a few milligrams of sample with no need for repeated accurate measurements of the true temperature.

In theory, the melting of an entirely crystalline, pure substance at constant pressure is characterised by a heat of fusion ΔH_f in an infinitely narrow range, corresponding to the melting point T_0. A broadening of this range is a sensitive indicator of impurities. Hence, samples of the same substance, whose impurity contents vary by a few tenths of a per cent, give thermal diagrams that are visually distinct (see Figure 2.2.34.-2).

The determination of the molar purity by DSC is based on the use of a mathematical approximation of the integrated form of the Van't Hoff equation applied to the concentrations (not the activities) in a binary system [$\ln(1 - x_2) = -x_2$ and $T \times T_0 = T_0^2$]:

$$T = T_0 - \frac{RT_0^2}{\Delta H_f} \times x_2 \qquad (1)$$

x_2 = mole fraction of the impurity i.e. the number of molecules of the impurity divided by the total number of molecules in the liquid phase (or molten phase) at temperature T (expressed in kelvins),

T_0 = melting point of the chemically pure substance, in kelvins,

ΔH_f = molar heat of fusion of the substance, in joules,

R = gas constant for ideal gases, in joules·kelvin^{-1}·mole^{-1}.

Hence, the determination of purity by DSC is limited to the detection of impurities forming a eutectic mixture with the principal compound and present at a mole fraction of less than 2 per cent in the substance to be examined.

This method cannot be applied to:

- amorphous substances,
- solvates or polymorphic compounds that are unstable within the experimental temperature range,
- impurities forming solid solutions with the principal substance,
- impurities that are insoluble in the liquid phase or in the melt of the principal substance.

During the heating of the substance to be examined, the impurity melts completely at the temperature of the eutectic mixture. Above this temperature, the solid phase contains

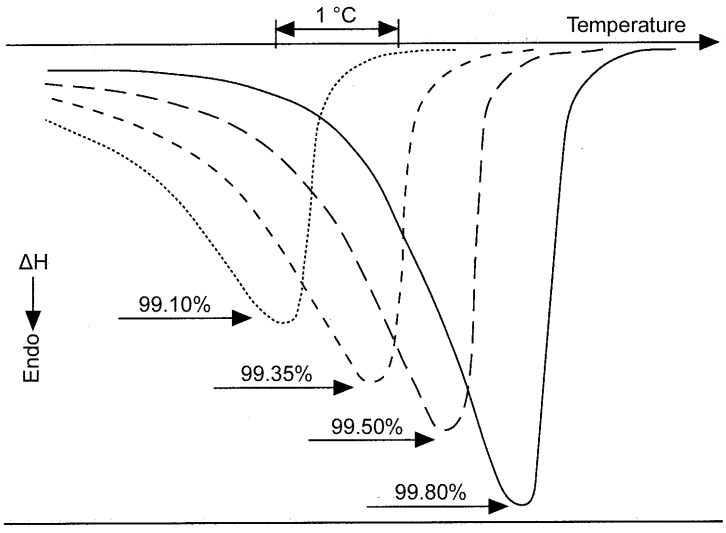

Figure 2.2.34.-2. – *Thermal diagrams according to purity*

only the pure substance. As the temperature increases progressively from the temperature of the eutectic mixture to the melting point of the pure substance, the mole fraction of impurity in the liquid decreases constantly, since the quantity of liquified pure substance increases constantly. For all temperatures above the eutectic point:

$$x_2 = \frac{1}{F} \times x_2^* \qquad (2)$$

F = molten fraction of the analysed sample,

x_2^* = mole fraction of the impurity in the analysed sample.

When the entire sample has melted, $F = 1$ and $x_2 = x_2^*$.

If equation (2) is combined with equation (1), the following equation is obtained:

$$T = T_0 - \frac{x_2^* R T_0^2}{\Delta H_f} \times \frac{1}{F}$$

The value of the heat of fusion is obtained by integrating the melting peak.

The melting point T_0 of the pure substance is extrapolated from the plot of $1/F$ versus the temperature expressed in kelvins. The slope α of the curve, obtained after linearisation, if necessary, corresponding to $RT_0^2 \frac{x_2^*}{\Delta H_f}$ allows x_2^* to be evaluated.

The fraction x_2^*, multiplied by 100 gives the mole fraction in per cent for the total eutectic impurities.

THERMOMICROSCOPY

Phase changes may be visualised by thermomicroscopy, a method which enables a sample subjected to a programmed temperature change to be examined, in polarised light, under a microscope.

The observations made in thermomicroscopy allow the nature of the phenomena detected using thermogravimetry and differential thermal analysis to be clearly identified.

Apparatus. The apparatus consists of a microscope fitted with a light polariser, a hot plate, a temperature and heating rate and/or cooling rate programmer and a recording system for the transition temperatures. A video camera and video recorder may be added.

01/2008:20235

2.2.35. OSMOLALITY

Osmolality is a practical means of giving an overall measure of the contribution of the various solutes present in a solution to the osmotic pressure of the solution.

An acceptable approximation for the osmolality ξ_m of a given aqueous solution is given by:

$$\xi_m = \upsilon m \Phi$$

If the solute is not ionised, $\upsilon = 1$; otherwise υ is the total number of ions already present or formed by solvolysis from one molecule of solute.

m = molality of the solution, that is the number of moles of solute per kilogram of solvent,

Φ = molal osmotic coefficient which takes account of the interactions between ions of opposite charge in the solution. It is dependent on the value of m. As the complexity of solutions increases, Φ becomes difficult to measure.

The unit of osmolality is osmole per kilogram (osmol/kg), but the submultiple milliosmole per kilogram (mosmol/kg) is usually used.

Unless otherwise prescribed, osmolality is determined by measurement of the depression of freezing point. The following relationship exists between the osmolality and the depression of freezing point ΔT:

$$\xi_m = \frac{\Delta T}{1.86} \times 1000 \text{ mosmol/kg}$$

Apparatus. The apparatus (osmometer) consists of:

– a means of cooling the container used for the measurement,

– a system for measuring temperature consisting of a resistor sensitive to temperature (thermistor), with an appropriate current or potential-difference measurement device that may be graduated in temperature depression or directly in osmolality,

– a means of mixing the sample is usually included.

Method. Prepare reference solutions as described in Table 2.2.35.-1, as required. Determine the zero of the apparatus using *water R*. Calibrate the apparatus using the reference solutions: introduce 50 µl to 250 µl of sample into the measurement cell and start the cooling system. Usually, the mixing device is programmed to operate at a temperature below that expected through cryoscopic depression to prevent supercooling. A suitable device indicates attainment of equilibrium. Before each measurement, rinse the measurement cell with the solution to be examined.

Table 2.2.35.-1. – *Reference solutions for osmometer calibration*

Mass in grams of *sodium chloride R* per kilogram of *water R*	Real osmolality (mosmol/kg)	Ideal osmolality (mosmol/kg)	Molal osmotic coefficient	Cryoscopic depression (°C)
3.087	100	105.67	0.9463	0.186
6.260	200	214.20	0.9337	0.372
9.463	300	323.83	0.9264	0.558
12.684	400	434.07	0.9215	0.744
15.916	500	544.66	0.9180	0.930
19.147	600	655.24	0.9157	1.116
22.380	700	765.86	0.9140	1.302

Carry out the same operations with the test sample. Read directly the osmolality or calculate it from the measured depression of freezing point. The test is not valid unless the value found is within two values of the calibration scale.

01/2008:20236

2.2.36. POTENTIOMETRIC DETERMINATION OF IONIC CONCENTRATION USING ION-SELECTIVE ELECTRODES

Ideally, the potential E of an ion-selective electrode varies linearly with the logarithm of the activity a_i of a given ion, as expressed by the Nernst equation:

$$E = E_0 + 2.303\frac{RT}{z_i F}\log a_i$$

E_0 = part of the constant potential due to the apparatus used,

R = gas constant,

T = absolute temperature,

F = Faraday's number,

z_i = charge number of the ion including its sign.

At a constant ionic strength, the following holds:

$$E = E_0 + \frac{k}{z_i}\log f C_i$$

C_i = molar concentration of the ion,

f = the activity coefficient ($a_i = fC_i$),

k = $\dfrac{RT}{F}$

If: $E_0 + \dfrac{k}{z_i}\log f = E_0'$ and $S = \dfrac{k}{z_i}$

S = slope of the calibration curve of the electrode,

the following holds: $E = E_0' + S\log C_i$

and for $-\log C_i = pC_i$: $E = E_0' - SpC_i$.

The potentiometric determination of the ion concentration is carried out by measuring the potential difference between two suitable electrodes immersed in the solution to be examined; the indicator electrode is selective for the ion to be determined and the other is a reference electrode.

Apparatus. Use a voltmeter allowing measurements to the nearest 0.1 millivolt and whose input impedance is at least one hundred times greater than that of the electrodes used.

Ion-selective electrodes may be primary electrodes with a crystal or non-crystal membrane or with a rigid matrix (for example, glass electrodes), or electrodes with charged (positive or negative) or uncharged mobile carriers, or sensitised electrodes (enzymatic-substrate electrodes, gas-indicator electrodes). The reference electrode is generally a silver–silver chloride electrode or a calomel electrode, with suitable junction liquids producing no interference.

Procedure. Carry out each measurement at a temperature constant to ± 0.5 °C, taking into account the variation of the slope of the electrode with temperature (see Table 2.2.36.-1). Adjust the ionic strength and possibly the pH of the solution to be analysed using the buffer reagent described in the monograph and equilibrate the electrode by immersing it in the solution to be analysed, under slow and uniform stirring, until a constant reading is obtained.

Table 2.2.36.-1. - *Values of k at different temperatures*

Temperature (°C)	*k*
20	0.0582
25	0.0592
30	0.0602

If the electrode system is used frequently, check regularly the repeatability and the stability of responses, and the linearity of the calibration curve or the calculation algorithm in the range of concentrations of the test solution; if not, carry out the test before each set of measurements. The response of the electrode may be regarded as linear if the slope S of the calibration curve is approximately equal to k/z_i, per unit of pC_i.

METHOD I (DIRECT CALIBRATION)

Measure at least three times in succession the potential of at least three reference solutions spanning the expected concentration of the test solution. Calculate the calibration curve, or plot on a chart the mean potential E obtained against the concentration of the ion to be determined expressed as $-\log C_i$ or pC_i.

Prepare the test solution as prescribed in the monograph; measure the potential three times and, from the mean potential, calculate the concentration of the ion to be determined using the calibration curve.

METHOD II (MULTIPLE STANDARD ADDITIONS)

Prepare the test solution as prescribed in the monograph. Measure the potential at equilibrium E_T of a volume V_T of this solution of unknown concentration C_T of the ion to be determined. Make at least three consecutive additions of a volume V_S negligible compared to V_T ($V_S \leq 0.01V_T$) of a reference solution of a concentration C_S known to be within the linear part of the calibration curve. After each addition, measure the potential and calculate the difference of potential ΔE between the measured potential and E_T. ΔE is related to the concentration of the ion to be determined by the equation:

$$\Delta E = S\log\left(1 + \frac{C_S V_S}{C_T V_T}\right)$$

or

$$10^{\frac{\Delta E}{S}} = 1 + \frac{C_S V_S}{C_T V_T}$$

V_T = volume of the test solution,

C_T = concentration of the ion to be determined in the test solution,

V_S = added volume of the reference solution,

C_S = concentration of the ion to be determined in the reference solution,

S = slope of the electrode determined experimentally, at constant temperature, by measuring the difference between the potentials obtained with two reference solutions whose concentrations differ by a factor of ten and are situated within the range where the calibration curve is linear.

Plot on a graph $10^{\frac{\Delta E}{S}}$ (*y*-axis) against V_S (*x*-axis) and extrapolate the line obtained until it intersects the *x*-axis. At the intersection, the concentration C_T of the test solution in the ion to be determined is given by the equation:

$$C_T = \frac{C_S V_S}{V_T}$$

METHOD III (SINGLE STANDARD ADDITION)

To a volume V_T of the test solution prepared as prescribed in the monograph, add a volume V_S of a reference solution containing an amount of the ion to be determined known to give a response situated in the linear part of the calibration curve. Prepare a blank solution in the same conditions. Measure at least three times the potentials of the test solution and the blank solution, before and after adding the reference solution. Calculate the concentration C_T of the ion to be analysed using the following equation and making the necessary corrections for the blank:

$$C_T = \frac{C_S V_S}{10^{\frac{\Delta E}{S}}(V_T + V_S) - V_T}$$

V_T = volume of the test solution or the blank,

C_T = concentration of the ion to be determined in the test solution,

V_S = added volume of the reference solution,

C_S = concentration of the ion to be determined in the reference solution,

ΔE = difference between the average potentials measured before and after adding V_S,

S slope of the electrode determined experimentally, at constant temperature, by measuring the difference between the potentials obtained from two reference solutions whose concentrations differ by a factor of ten and are situated within the range where the calibration curve is linear.

01/2008:20237

2.2.37. X-RAY FLUORESCENCE SPECTROMETRY(2)

Wavelength dispersive X-ray fluorescence spectrometry is a procedure that uses the measurement of the intensity of the fluorescent radiation emitted by an element having an atomic number between 11 and 92 excited by a continuous primary X-ray radiation. The intensity of the fluorescence produced by a given element depends on the concentration of this element in the sample but also on the absorption by the matrix of the incident and fluorescent radiation. At trace levels, where the calibration curve is linear, the intensity of the fluorescent radiation emitted by an element in a given matrix, at a given wavelength, is proportional to the concentration of this element and inversely proportional to the mass absorption coefficient of the matrix at this wavelength.

Method. Set and use the instrument in accordance with the instructions given by the manufacturer. Liquid samples are placed directly in the instrument; solid samples are first compressed into pellets, sometimes after mixing with a suitable binder.

To determine the concentration of an element in a sample, it is necessary to measure the net impulse rate produced by one or several standard preparations containing known amounts of this element in given matrices and to calculate or measure the mass absorption coefficient of the matrix of the sample to be analysed.

Calibration. From a calibration solution or a series of dilutions of the element to be analysed in various matrices, determine the slope of the calibration curve b_0 from the following equation:

$$b_0 \frac{1}{\mu_M} = \frac{I_C^N}{C}$$

μ_M = absorption coefficient of the matrix M, calculated or measured,

I_C^N = net impulse rate,

C = concentration of the element to be assayed in the standard preparation.

Mass absorption coefficent of the matrix of the sample. If the empirical formula of the sample to be analysed is known, calculate its mass absorption coefficient from the known elemental composition and the tabulated elemental mass absorption coefficients. If the elemental composition is unknown, determine the mass absorption coefficient of the sample matrix by measuring the intensity of the scattered X-radiation I_U (Compton scattering) from the following equation:

$$\frac{1}{\mu_{MP}} = a + bI_U$$

μ_{MP} = mass absorption coefficient of the sample,

I_U = scattered X-radiation.

Determination of the net pulse rate of the element to be determined in the sample. Calculate the net impulse rate I_{EP}^N of the element to be determined from the measured intensity of the fluorescence line and the intensity of the background line(s), allowing for any tube contaminants present.

Calculation of the trace content. If the concentration of the element is in the linear part of the calibration curve, it can be calculated using the following equation:

$$C = \frac{I_{EP}^N}{b_0 \frac{1}{\mu_{MP}}} \times f$$

f = dilution factor.

01/2008:20238

2.2.38. CONDUCTIVITY

The current I (in amperes) flowing in a conductor is directly proportional to the applied electromotive force E (in volts) and inversely proportional to the resistance R (in ohms) of the conductor:

$$I = \frac{E}{R}$$

(2) G. Andermann &M.W. Kemp, Analytical Chemistry 30 1306 (1958). Z.H. Kalman & L. Heller, Analytical Chemistry 34 946 (1962). R.C. Reynolds, Jr., The American Mineralogist 46 1133 (1963). R.O. Müller, Spectrochimica Acta 20 143 (1964). R.O. Müller, Spectrochemische Analyse mit Röntgenfluoreszenz, R. Oldenburg München-Wien (1967).

The conductivity (formerly called specific conductance) of a solution (κ) is, by definition, the reciprocal of resistivity (ρ). Resistivity is defined as the quotient of the electric field and the density of the current. The resistance R (in Ω) of a conductor of cross-section S (in cm^2) and length L (in cm) is given by the expression:

$$R = \rho \frac{L}{S}$$

$$\text{thus: } R = \frac{1}{\kappa} \times \frac{L}{S} \text{ or } \kappa = \frac{1}{R} \times \frac{L}{S}$$

L/S corresponds to the ideal cell constant.

The unit of conductivity in the International System is the siemens per metre ($S \cdot m^{-1}$). In practice, the electrical conductivity of a solution is expressed in siemens per centimetre ($S \cdot cm^{-1}$) or in microsiemens per centimetre ($\mu S \cdot cm^{-1}$). The unit of resistivity in the International System is the ohm-metre (Ω·m). The resistivity of a solution is generally expressed in ohm-centimetres (Ω·cm). Unless otherwise prescribed, the reference temperature for the expression of conductivity or resistivity is 25 °C.

The apparatus and operating procedure described below are applicable to laboratory measurement of conductivity greater than 10 $\mu S \cdot cm^{-1}$. The measurement of conductivity of water is dealt with in the relevant monographs.

APPARATUS

The apparatus used (conductivity meter or resistivity meter) measures the resistance of the column of liquid between the electrodes of the immersed measuring device (conductivity cell). The apparatus is supplied with alternating current to avoid the effects of electrode polarisation. It is equipped with a temperature probe and a temperature compensation device.

The conductivity cell contains 2 parallel platinum electrodes coated with platinum black, each with a surface area S, and separated from the other by a distance L. Both are generally protected by a glass tube. Other types of cells may also be used.

OPERATING PROCEDURE

Determination of the cell constant

Choose a conductivity cell that is appropriate for the properties and conductivity of the solution to be examined. The higher the expected conductivity, the higher the cell constant that must be chosen (low ρ). Commonly used conductivity cells have cell constants of the order of 0.1 cm^{-1}, 1 cm^{-1} and 10 cm^{-1}. Use a certified reference material, for example a solution of potassium chloride, that is appropriate for the measurement. The conductivity value of the certified reference material, should be near the expected conductivity value of the solution to be examined. Other certified reference materials may be used especially for cells having a constant of 0.1 cm^{-1}. Rinse the cell several times with *distilled water R* and at least twice with the certified reference material used for the determination of the cell constant of the conductivity cell. Measure the resistance of the conductivity cell using the certified reference material at 25 ± 1 °C. The cell constant K_{cell} (in cm^{-1}) depends on the geometry of the conductivity cell and is given by the expression:

$$K_{cell} = R_{CRM} \times \kappa_{CRM}$$

R_{CRM} = measured resistance, expressed in mega-ohms,

κ_{CRM} = conductivity of the certified reference material solution used, expressed in microsiemens per centimetre.

The measured constant K_{cell} of the conductivity cell must be within 5 per cent of the value indicated.

If the determination of the cell constant is carried out at a different temperature than that indicated for the certified reference material, the conductivity value may be calculated from the following expression:

$$\kappa_T = \kappa_{TCRM} \times [1 + \alpha (T - T_{CRM})]$$

κ_T = value of conductivity at the different temperature,

κ_{TCRM} = value of conductivity of the certified reference material,

T = temperature set for calibration,

T_{CRM} = temperature indicated for the certified reference material,

α = temperature coefficient for the conductivity value of the certified reference material; for potassium chloride α = 0.021.

Determination of the conductivity of the solution to be examined

After calibrating the apparatus with a certified reference material solution, rinse the conductivity cell several times with *distilled water R* and at least twice with the aqueous solution to be examined. Carry out successive measurements as described in the monograph.

01/2008:20239

2.2.39. MOLECULAR MASS DISTRIBUTION IN DEXTRANS

Examine by size-exclusion chromatography (*2.2.30*).

Test solution. Dissolve 0.200 g of the substance to be examined in the mobile phase and dilute to 10 ml with the mobile phase.

Marker solution. Dissolve 5 mg of *glucose R* and 2 mg of *dextran V_0 CRS* in 1 ml of the mobile phase.

Calibration solutions. Dissolve separately in 1 ml of the mobile phase 15 mg of *dextran 4 for calibration CRS*, 15 mg of *dextran 10 for calibration CRS*, 20 mg of *dextran 40 for calibration CRS*, 20 mg of *dextran 70 for calibration CRS* and 20 mg of *dextran 250 for calibration CRS*.

System suitability solution. Dissolve either 20 mg of *dextran 40 for performance test CRS* (for dextran 40) or 20 mg of *dextran 60/70 for performance test CRS* (for dextran 60 and dextran 70) in 1 ml of the mobile phase.

The chromatographic procedure may be carried out using:

- a column 0.3 m long and 10 mm in internal diameter, packed with *cross-linked agarose for chromatography R* or a series of columns, 0.3 m long and 10 mm in internal diameter, packed with *polyether hydroxylated gel for chromatography R*,
- as the mobile phase, at a flow rate of 0.5-1 ml/min, kept constant to ± 1 per cent per hour, a solution containing 7 g of *anhydrous sodium sulphate R* and 1 g of *chlorobutanol R* in 1 litre of *water R*,
- as detector a differential refractometer,
- a 100 µl to 200 µl loop injector,

maintaining the system at a constant temperature (± 0.1 °C).

CALIBRATION OF THE CHROMATOGRAPHIC SYSTEM

Carry out replicate injections of the chosen volume of the marker solution. The chromatogram shows 2 peaks, the first of which corresponds to *dextran V_0 CRS* and the second of which corresponds to *dextrose R*. From the elution volume

of the peak corresponding to dextran V_0, calculate the void volume V_0 and from the peak corresponding to dextrose, calculate the total volume V_t.

Inject the chosen volume of each of the calibration solutions. Draw carefully the baseline of each of the chromatograms. Divide each chromatogram into p (at least 60) equal vertical sections (corresponding to equal elution volumes). In each section i, corresponding to an elution volume V_i measure the height (y_i) of the chromatogram line above the baseline and calculate the coefficient of distribution K_i using the expression:

$$\frac{(V_i - V_0)}{(V_t - V_0)} \qquad (1)$$

V_0 = void volume of the column, determined using the peak corresponding to *dextran V_0 CRS* in the chromatogram obtained with the marker solution,

V_t = total volume of the column, determined using the peak corresponding to glucose in the chromatogram obtained with the marker solution,

V_i = elution volume of section i in the chromatogram obtained with each of the calibration solutions.

Carry out the calibration using either of the following methods.

Calibration by plotting of the curve. For each of the dextrans for calibration calculate the coefficient of distribution K_{max} corresponding to the maximum height of the chromatographic line, using expression (1). Plot on semilogarithmic paper the values of K_{max} (on the x-axis) against the declared molecular mass at the maximum height of the chromatographic line (M_{max}) of each of the dextrans for calibration and glucose. Draw a first calibration curve through the points obtained, extrapolating it from the point K_{max} obtained with *dextran 250 for calibration CRS* to the lowest K value obtained for this CRS (Figure 2.2.39.-1). Using this first calibration curve, transform, for each chromatogram, all K_i values into the corresponding molecular mass M_i, thus obtaining the molecular mass distribution. Calculate for each dextran for calibration the average molecular mass M_w using equation (3) below. If the calculated values for M_w do not differ by more than 5 per cent from those declared for each of the dextrans for calibration and the mean difference is within ± 3 per cent, the calibration curve is approved. If not, move the calibration curve along the y-axis and repeat the procedure above until the calculated and the declared values for M_w do not differ by more than 5 per cent.

Calibration by calculation of the curve. Calculate from equations (2) and (3) below, using a suitable method(3), values for b_1, b_2, b_3, b_4 and b_5 that give values of M_w within 5 per cent of the declared values of each of the dextrans for calibration and 180 ± 2 for glucose:

$$M_i = b_5 + e^{\left(b_4 + b_1 K_i + b_2 K_i^2 + b_3 K_i^3\right)} \qquad (2)$$

$$\overline{M}_w = \frac{\sum_{i=1}^{p} (y_i M_i)}{\sum_{i=1}^{p} y_i} \qquad (3)$$

p = number of sections dividing the chromatograms,

y_i = height of the chromatographic line above the baseline in section i,

M_i = molecular mass in section i.

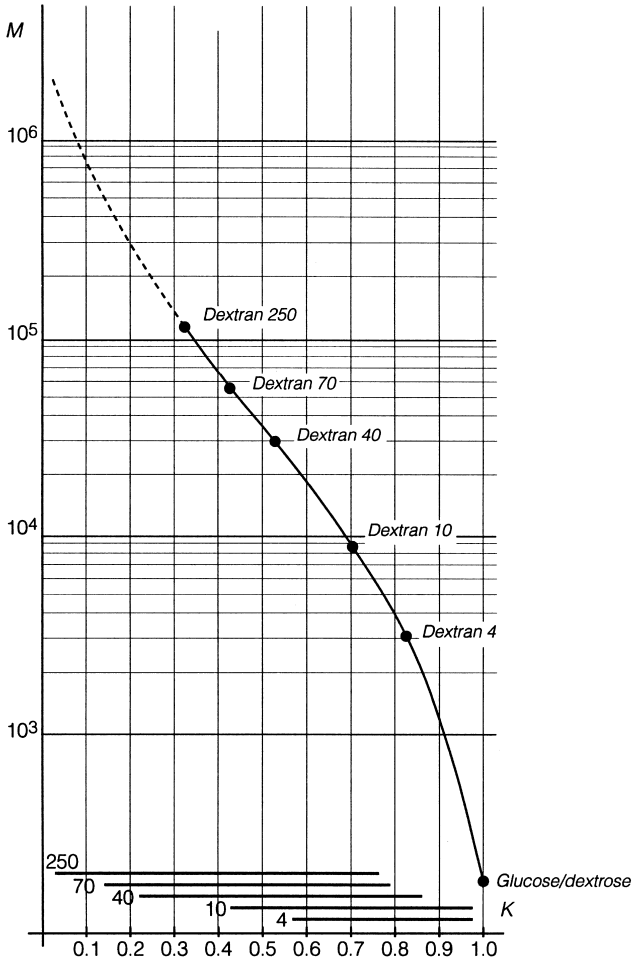

Figure 2.2.39.-1. - *Example of a calibration curve.*

The dotted line corresponds to the part of the curve that is extrapolated. Horizontal lines at the bottom of the figure represent the width and the position of the chromatographic line obtained with each of the dextrans for calibration.

SYSTEM SUITABILITY

Inject the chosen volume of the appropriate system suitability solution.

Average molecular mass of dextran for performance test CRS. Calculate the average molecular mass M_w as indicated under Calibration of the chromatographic system, using either the plotted calibration curve or the values obtained above for b_1, b_2, b_3, b_4 and b_5. The test is not valid unless M_w is:

– 41 000 to 47 000 (*dextran 40 for performance test CRS*),

– 67 000 to 75 000 (*dextran 60/70 for performance test CRS*).

(3) An iterative method such as the Gauss-Newton method modified by Hartley is suitable (see O. Hartley, Tecnometrics, 3 (1961) and G. Nilsson and K. Nilsson, J. Chromat. 101, 137 (1974)). A curve-fitting programme for microcomputers, capable of non-linear regression, may be used.

Average molecular mass of the 10 per cent high-fraction dextran. Calculate M_w for the 10 per cent high-fraction dextran eluted through section n using the equation:

$$M_w = \frac{\sum_{i=1}^{n} (y_i M_i)}{\sum_{i=1}^{n} y_i} \quad (4)$$

in which n is defined by the expressions:

$$\sum_{i=1}^{n} y_i \leq 0.1 \left(\sum_{i=1}^{p} y_i \right) \quad (5)$$

$$\sum_{i=1}^{n+1} y_i > 0.1 \left(\sum_{i=1}^{p} y_i \right) \quad (6)$$

p = number of sections dividing the chromatograms,

y_i = height of the chromatographic line above the baseline in section i,

M_i = molecular mass in section i.

The test is not valid unless M_w of the 10 per cent high fraction dextran is:

– 110 000 to 130 000 (*dextran 40 for performance test CRS*),

– 190 000 to 230 000 (*dextran 60/70 for performance test CRS*).

Average molecular mass of the 10 per cent low-fraction dextran. Calculate M_w for the 10 per cent low-fraction dextran eluted in and after section m using the expression:

$$M_w = \frac{\sum_{i=m}^{p} (y_i M_i)}{\sum_{i=m}^{p} y_i} \quad (7)$$

in which m is defined by the expressions:

$$\sum_{i=m}^{p} y_i \leq 0.1 \left(\sum_{i=1}^{p} y_i \right) \quad (8)$$

$$\sum_{i=m-1}^{p} y_i > 0.1 \left(\sum_{i=1}^{p} y_i \right) \quad (9)$$

p = number of sections dividing the chromatograms,

y_i = height of the chromatographic line above the baseline in section i,

M_i = molecular mass in section i.

The test is not valid unless M_w of the 10 per cent low-fraction dextran is:

– 6000 to 8500 (*dextran 40 for performance test CRS*),

– 7000 to 11 000 (*dextran 60/70 for performance test CRS*).

MOLECULAR MASS DISTRIBUTION OF THE DEXTRAN TO BE ANALYSED

Inject the chosen volume of the test solution and calculate M_w of the total molecular mass distribution, M_w of the 10 per cent high-fraction dextran and M_w of the 10 per cent low-fraction dextran as indicated under System suitability.

01/2008:20240

2.2.40. NEAR-INFRARED SPECTROPHOTOMETRY

Near-infrared (NIR) spectrophotometry is a technique with wide and varied applications in pharmaceutical analysis. The NIR spectral range extends from about 780 nm to about 2500 nm (from about 12 800 cm^{-1} to about 4000 cm^{-1}). In some cases the most useful information is found in the spectral range from about 1700 nm to about 2500 nm (from about 6000 cm^{-1} to 4000 cm^{-1}). NIR spectra are dominated by C-H, N-H, O-H and S-H overtone resonances and combinations of fundamental vibrational modes; they have a high informative character if the information is extracted by suitable chemometric algorithms. NIR bands are much weaker than the fundamental mid-IR vibrations from which they originate. Because molar absorptivities in the NIR range are low, radiation typically penetrates several millimeters into materials, including solids. Furthermore, many materials such as glass are relatively transparent in this region.

Measurements can be made directly on *in situ* samples, in addition to standard sampling and testing procedures. Physical as well as chemical information, both qualitative and quantitative, is available from NIR spectra. However, direct comparison of the spectrum obtained with the substance being examined with a reference spectrum of a chemical reference substance, as used in infrared absorption spectrophotometry, is not appropriate. Suitable validated mathematical treatment of the data is required.

NIR spectrophotometry has a wide variety of applications for both chemical and physical analysis, for example:

chemical analysis

– identification of active substances, excipients, dosage forms, manufacturing intermediates, chemical raw materials and packaging materials,

– quantification of active substances and excipients, determination of chemical values such as hydroxyl value, iodine value, acid value, determination of water content, determination of degree of hydroxylation, control of solvent content,

– process control.

physical analysis

– crystalline form and crystallinity, polymorphism, pseudopolymorphism, particle size,

– dissolution behaviour, disintegration pattern, hardness,

– examination of film properties,

– process control, for example monitoring of blending and granulation.

Measurements in the NIR region are influenced by many chemical and physical factors as described below; reproducibility and relevance of results depend on control of these factors and measurements are usually valid only for a defined calibration model.

APPARATUS

NIR spectrophotometers are used for recording spectra in the region of about 780 nm to about 2500 nm (about 12 800 cm^{-1} to about 4000 cm^{-1}). All NIR measurements are based on passing light through or into a sample and measuring the attenuation of the emerging (transmitted, scattered or reflected) beam. Spectrophotometers for measurement in the NIR region consist of a suitable light source, a monochromator or interferometer. Common monochromators are acousto-optical tuneable filters (AOTF), gratings or prisms. High intensity light sources such as quartz or tungsten lamps or similar are used. The tungsten lamp light source can be highly stabilised. Therefore many NIR instruments have the single-beam design. Silicon, lead sulphide, indium arsenide, indium gallium arsenide, mercury cadmium telluride (MCT) and deuterated triglycine sulphate are commonly used detector materials. Conventional cuvette sample holders, fibre-optic probes, transmission dip cells and spinning or traversing sample holders are a few common sampling devices. The selection is based on the intended application, paying particular attention to the suitability of the sampling system for the type of sample to be analysed. Suitable data processing and evaluation units are usually part of the system.

MEASUREMENT METHODS

Transmission mode. Transmittance (T) is a measure of the decrease in radiation intensity at given wavelengths when radiation is passed through the sample. The sample is placed in the optical beam between the source and detector. The arrangement is analogous to that in many conventional spectrophotometers and the result can be presented directly in terms of transmittance (T) or/and absorbance (A).

T = $\frac{I}{I_0}$,

I_0 = intensity of incident radiation,

I = intensity of transmitted radiation,

A = $-\log_{10} T = \log_{10}\left(\frac{1}{T}\right) = \log_{10}\left(\frac{I_o}{I}\right)$.

Diffuse reflection mode. The diffuse reflection mode gives a measure of reflectance (R), the ratio of the intensity of light reflected from the sample (I) to that reflected from a background or reference reflective surface (I_r). NIR radiation can penetrate a substantial distance into the sample, where it can be absorbed by vibrational combinations and overtone resonances of the analyte species present in the sample. Non-absorbed radiation is reflected back from the sample to the detector. NIR reflectance spectra are typically obtained by calculating and plotting log ($1/R$) versus the wavelength or wavenumbers.

R = $\frac{I}{I_r}$,

I = intensity of light diffusively reflected from the sample,

I_r = intensity of light reflected from the background or reference reflective surface,

A_R = $\log_{10}\left(\frac{1}{R}\right) = \log_{10}\left(\frac{I_r}{I}\right)$.

Transflection mode. This mode is a combination of transmittance and reflectance. In the measurement of transflectance (T^*) a mirror or a diffuse reflectance surface is used to reflect the radiation transmitted through the sample a second time and thus doubling the pathlength. Non-absorbed radiation is reflected back from the sample to the detector.

T^* = $\frac{I}{I_T}$,

I_T = intensity of transflected radiation, without sample,

I = intensity of transmitted and reflected radiation measured with the sample,

A^* = $\log_{10}\left(\frac{1}{T^*}\right)$.

SAMPLE PREPARATION/PRESENTATION

Transmission mode. The measurement of transmittance (T) is dependent on a background transmittance spectrum for its calculation. A background reference can be air, an empty cell, and a solvent blank or in special cases a reference sample. The method generally applies to liquids, diluted or undiluted, dispersions, solutions and solids. For transmittance measurements of solids, a suitable sample accessory is to be used. The samples are examined in a cell of suitable pathlength (generally 0.5-4 mm), transparent to NIR radiation, or by immersion of a fibre optic probe of a suitable configuration, which yields a spectrum situated in a zone of transmission compatible with the specifications of the apparatus and appropriate for the intended purpose.

Diffuse reflection mode. This method generally applies to solids. The sample is examined in a suitable device. Care must be taken to make the measuring conditions as reproducible as possible from one sample to another. When immersing a fibre optic probe in the sample, care must be taken in the positioning of the probe to ensure that it remains stationary during the acquisition of the spectra and that the measuring conditions are as reproducible as possible from one sample to another. The reflected radiation of a background reference is scanned to obtain the baseline, and then the reflectance of one or more analytical samples is measured. Common reflectance references are ceramic tiles, perfluorinated polymers and gold. Other suitable materials may be used. Only spectra measured against a background possessing the same optical properties can be directly compared with one another. The particle size, water of hydration and state of solvation must be taken into consideration.

Transflection mode. A reflector is placed behind the sample so as to double the pathlength. This configuration can be adopted to share the same instrument geometry with reflectance and fibre optic probe systems where the source and the detector are on the same side of the sample. The sample is examined in a cell with a mirror or a suitable diffusive reflector, made either of metal or of an inert substance (for example titanium dioxide) not absorbing in the NIR region.

FACTORS AFFECTING SPECTRAL RESPONSE

Sample temperature. This parameter is important for aqueous solutions and many liquids, where a difference of a few degrees can result in substantial spectral changes. Temperature is also an important parameter for solids and powders containing water.

Moisture and solvent residues. Moisture and solvent residues present in the samples will contribute significant absorption bands in the NIR region.

Sample thickness. Sample thickness is a known source of spectral variability and must be understood and/or controlled. For example, in a reflection measurement the

sample may be "infinitely" thick, or thinner samples of constant thickness must have a stable, diffusively reflecting backing material of constant, and preferably high reflectivity.

Sample optical properties. In solids, both surface and bulk scattering properties of samples must be taken into account. Spectra of physically, chemically or optically heterogeneous samples may require sample averaging by increasing the beam size or examining multiple samples or spinning the probe. Certain factors such as differing degree of compaction or particle size in powdered materials and surface finish can cause significant spectral differences.

Polymorphism. The variations in crystalline structure (polymorphism) influence the spectra. Hence different crystalline forms as well as the amorphous form of a solid may be distinguished from one another on the basis of their NIR spectra. Where multiple crystalline forms are present, care must be taken to ensure that the calibration standards have a distribution of forms relevant to the intended application.

Age of samples. Samples may exhibit changes in their chemical, physical or optical properties over time. Care must be taken to ensure that samples for NIR analysis are representative of those used for calibration. If samples of different age are to be analysed, potential differences in the properties must be accounted for.

CONTROL OF INSTRUMENT PERFORMANCE

Use the apparatus according to the manufacturer's instructions and carry out the prescribed verification at regular intervals, according to the use of the apparatus and the substances to be tested.

Verification of the wavelength scale (except for filter apparatus). Verify the wavelength scale employed, generally in the region between about 780 nm and about 2500 nm (about 12 800 cm^{-1} to about 4000 cm^{-1}) or in the intended spectral range using one or more suitable wavelength standards which have characteristic maxima or minima within the range of wavelengths to be used. For example, methylene chloride or a mixture of rare-earth oxides are suitable reference materials. Take one spectrum with the same spectral resolution used to obtain the certified value, and measure the position of at least 3 peaks distributed over the range used. Acceptable tolerances are ± 1 nm at 1200 nm, ± 1 nm at 1600 nm and ± 1.5 nm at 2000 nm (± 8 cm^{-1} at 8300 cm^{-1}, ± 4 cm^{-1} at 6250 cm^{-1} and ± 4 cm^{-1} at 5000 cm^{-1}). For the reference material used, apply the tolerance for the nearest wavelength (wavenumber) from the above for each peak used. For FT instruments, the calibration of the wavenumber scale may be performed using a narrow water-vapour line at 7299.86 cm^{-1} or a narrow line from a certified material. For rare-earth oxides, NIST 1920 (a) is the most appropriate reference.

Measurement in transmission mode. Methylene chloride R may be used at an optical pathlength of 1.0 mm. Methylene chloride has characteristic sharp bands at 1155 nm, 1366 nm, 1417 nm, 1690 nm, 1838 nm, 1894 nm, 2068 nm and 2245 nm. The bands at 1155 nm, 1417 nm, 1690 nm and 2245 nm are used for calibration. Other suitable standards may also be used.

Measurement in diffuse reflection (reflectance) mode. A mixture of dysprosium, holmium and erbium oxides (1+1+1 by mass) or other certified material may be used. This reference material exhibits characteristic peaks at 1261 nm, 1681 nm and 1935 nm. If it is not possible to use external solid standards and if measurements of diffuse reflection are carried out in cells or if fibre optic probes are used, a suspension of 1.2 g of *titanium dioxide R* in about 4 ml of *methylene chloride R*, vigorously shaken, is used directly in the cell or probe. The spectrum is recorded after 2 min. Titanium dioxide has no absorption in the NIR range. Spectra are recorded with a maximum nominal instrument bandwidth of 10 nm at 2500 nm (16 cm^{-1} at 4000 cm^{-1}). Measurement is made of the position of at least 3 peaks distributed over the range used. The acceptance tolerances are given under Verification of the wavelength scale. For the reference material used, apply the tolerance for the nearest wavelength (wavenumber) for each peak used.

Verification of the wavelength repeatability (except for filter apparatus). Verify the wavelength repeatability using suitable standards. The standard deviation of the wavelength is consistent with the specifications of the instrument manufacturer.

Verification of photometric linearity and response stability. Verification of photometric linearity is demonstrated with a set of transmission or reflection standards with known values of transmittance or reflectance in percentage. For reflectance measurements, carbon-doped polymer standards are available. At least 4 reference standards in the range of 10-90 per cent such as 10 per cent, 20 per cent, 40 per cent and 80 per cent with respective absorbance values of 1.0, 0.7, 0.4 and 0.1 are used. If the system is used for analytes with absorbances higher than 1.0, a 2 per cent and/or 5 per cent standard is added to the set. Plot the observed absorbance values against the reference absorbance values and perform a linear regression. Acceptable tolerances are 1.00 ± 0.05 for the slope and 0.00 ± 0.05 for the intercept.

Spectra obtained from reflectance standards are subject to variability due to the difference between the experimental conditions under which they were factory-calibrated and those under which they are subsequently put to use. Hence, the percentage reflectance values supplied with a set of calibration standards may not be useful in the attempt to establish an "absolute" calibration for a given instrument. But as long as the standards do not change chemically or physically and the same reference background is used as was used to obtain the certified values, subsequent measurements of the same standards under identical conditions including precise sample positioning give information on long-term stability of the photometric response. A tolerance of ± 2 per cent is acceptable for long-term stability; this is only necessary if spectra are used without pre-treatment.

Verification of photometric noise. Determine the photometric noise using a suitable reflectance standard, for example white reflective ceramic tiles or reflective thermoplastic resins (for example, PTFE). Scan the reflection standard over a suitable wavelength/wavenumber range in accordance with the manufacturer's recommendation and calculate the photometric noise as peak-to-peak noise. The value is approximately twice the standard deviation. The photometric noise is consistent with the specification of the spectrophotometer.

IDENTIFICATION AND CHARACTERISATION (QUALITATIVE ANALYSIS)

Establishment of a spectral reference library. Record the spectra of a suitable number of batches of the substance which have been fully tested according to established specifications and which exhibit the variation typical for the substance to be analysed (for example, manufacturer, physical form, particle size). The set of spectra represents the information for identification and characterisation that defines the similarity border for that substance and is the entry for that substance in the spectral library used to identify the substance. The number of substances in the library depends on the specific application, but libraries that

are too big can cause some difficulties in discriminating between different materials and in validation. All spectra in the library used have the same:

- spectral range and number of data points,
- technique of measurement,
- data pre-treatment.

If sub-groups (libraries) are created, the above criteria are applied independently for each group. The collection of spectra in the library may be represented in different ways defined by the mathematical technique used for identification. These may be:

- all individual spectra representing the substance,
- a mean spectrum of each batch of substance,
- if necessary, a description of the variability within the substance spectra.

Electronic raw data for the preparation of the spectral library must be archived.

Pre-treatment of data. In many cases, and particularly for reflection mode spectra, some form of mathematical pretreatment of the spectrum may be useful before the development of a classification or calibration model. The aim can be, for example, to reduce baseline variations, to reduce the impact of known variations that are interfering in the subsequent mathematical models, or to compress data before use. Typical methods are multiplicative scatter correction (MSC), the Kubelka-Munk transforms, spectral compression techniques that may include windowing and noise reduction and the numerical calculation of the first- or second-order derivative of the spectrum. Higher-order derivatives are not recommended. In some cases spectra may also be normalised, for example against the maximum absorbance, the mean absorbance or the integrated absorbance area under the spectrum.

Caution must be excercised when performing any mathematical transformation, as artefacts can be introduced or essential information (important with qualification methods) can be lost. An understanding of the algorithm is required and in all cases the rationale for the use of transform must be documented.

Data evaluation. Direct comparison of the spectrum of the substance under investigation is made with the individual or mean reference spectra of all substances in the database on the basis of their mathematical correlation or other suitable algorithms. A set of known reference mean spectra and the variability around this mean can be used with an algorithm for classification. There are different algorithms based on principal component analysis (PCA) combined with cluster analysis, SIMCA (soft independent modelling by class analogy), COMPARE functions using filters or UNEQ (unequal dispersed class) and others used in the software of NIR instruments or supplied as third-party software. The reliability of the algorithm chosen for a particular application has to be validated. For example, correlation coefficient, the sum of squared residuals or the distance using cluster analysis must comply with the acceptance limits defined in the validation procedure.

Validation of the database

Specificity. The selectivity of the classification using database spectra for positive identification of a given material and adequate discrimination against other materials in the database is to be established during the validation procedure. Acceptance thresholds are established. High thresholds achieve a higher discriminatory power, but may cause some errors due to the own variability of materials. Lower thresholds solve these problems, but could produce ambiguous results. Potential challenges must be addressed to the spectral database. These can be materials received on site that are similar to database members in visual appearance, chemical structure or by name. This challenge must fail identification. Independent samples of materials represented in the database, but not used to create it (i.e. different batches, blends) must give positive identification when analysed.

Robustness. The robustness of the qualitative procedure must also be challenged to test the effect of minor changes to normal operating conditions on the analysis. There must be no changes to pre-processing and calibration algorithm parameters. Typical challenges are:

- effect of differences across operators on variations in environmental conditions (for example, temperature and humidity in the laboratory),
- effect of sample temperature, sample positioning on the optical window and probe depth and compression/packing of material,
- replacement of instrument parts or sampling presentation devices.

QUANTITATIVE ANALYSIS

Establishment of a spectral reference library for a calibration model. Calibration is the process of constructing a mathematical model to relate the response from an analytical instrument to the properties of the samples. Any calibration algorithm that can be clearly defined in an exact mathematical expression and gives suitable results can be used. Record spectra of a suitable number of samples with known values of the content throughout the range to be measured (for example, content of water). Wavelengths used in the calibration model can be compared to the known bands of the analyte and those of the matrix to verify that the bands of the analyte of interest are being used by the calibration. Establish the calibration model with about two-thirds of the measured samples. Compare the remaining one-third of the measured samples with the database. All samples must give quantitative results within a precision interval as defined by the intended purpose of the method. Correct quantification must be demonstrated in the presence of variations in the matrix within the specified range. Multiple linear regression (MLR), partial least squares (PLS) and principal component regression (PCR) are commonly used. For PLS or PCR calibrations, the coefficients or the loadings can be plotted and the regions of large coefficients compared with the spectrum of the analyte. Raw data for the preparation of the calibration model must be archived, without data pretreatment.

Pre-treatment of data. Data pre-treatment can be defined as the mathematical transformation of the NIR spectral data to enhance spectral features and/or remove or reduce unwanted sources of variation prior to the development of the calibration model. Many suitable algorithms for data pre-treatment and calibration exist. The selection is based on the suitability for the intended use. Wavelength selection may enhance the efficiency of calibration models such as MLR (for example, in particle-size determination). It is useful to delete certain ranges of the wavelength scale in some cases, for example in the determination of water of hydration. Wavelength compression may be applied to the data.

Validation parameters. Analytical performance characteristics to be considered for demonstrating the validation of NIR methods are similar to those required

for any analytical procedure. Specific acceptance criteria for each validation parameter must be consistent with the intended use of the method.

Specificity. The relative discriminatory power and selectivity for quantitative determination must be similar to those mentioned under Qualitative analysis. The extent of specificity testing is dependent on the application and the risks being controlled. Variations in matrix concentrations within the operating range of the method must not affect the quantitative measurement significantly.

Linearity. The validation of linearity involves the correlation of NIR results calculated from NIR responses within the used algorithms to reference method results distributed throughout the defined range of the calibration model. Actual NIR responses that are non-linear may still be valid.

Range. The range of analyte reference values defines the range of the NIR method and quantitation limits of the method. Controls must be in place to ensure that results outside the validated range are not accepted.

Accuracy. This can be determined by comparison with the validation method or with known samples (samples of blank and added amounts of tested substance). Accuracy can be indicated by the standard error of prediction (SEP) of the NIR method that should be in close agreement with the data of the validated method. The SEP is the standard deviation of the residuals obtained from comparing the NIR results with analytical reference data for the specified samples. It is demonstrated by correlation of NIR results with analytical reference data, by comparison of the SEP to the reference method used for validation. Alternatively statistical comparison methods may be used to compare NIR results with reference values (paired *t*-test, bias evaluation).

Precision. This expresses the closeness of agreement between a series of measurements under the prescribed conditions. It is assessed by a minimum of 6 measurements performed according to the developed analytical method. Precision may be considered at 2 levels, repeatability (replicate measurements of the same sample with or without variation in sample positioning) and intermediate precision (replicate measurements by different analysts, different days of measurements).

Robustness. This includes the effects of variations of temperature, humidity, sample handling and the influence of instrument changes.

Outliers. Outlier results from NIR measurements of a sample containing an analyte outside the calibration range indicates that further testing is required. If further testing of the sample by an appropriate analytical method gives the analyte content within the specifications, this may be accepted and considered to have met the specifications. Thus an outlier result generated by NIR measurements of the sample may still meet specifications for the analyte of interest.

ONGOING MODEL EVALUATION

NIR models validated for use are subjected to ongoing performance evaluation and monitoring of validation parameters. If discrepancies are found, corrective action will be necessary. The degree of revalidation required depends on the nature of the changes. Revalidation of a qualitative model will be necessary when a new material is added to the reference library and may be necessary when changes in the physical properties of the material occur and when changes in the source of supply take place. Revalidation of a quantitative model is required on account of changes in the composition of the finished product, in the manufacturing process and in sources/grades of raw materials.

TRANSFER OF DATABASES

When databases are transferred to another instrument, spectral range, number of data points, spectral resolution and other parameters have to be taken into consideration. Further procedures and criteria must be applied to demonstrate that the model remains valid with the new database or new instrument.

DATA STORAGE

Store the electronic NIR spectra, libraries and data according to the current regulations.

Store the NIR spectra with the necessary data pre-treatment for the special use (for example identification, particle size analysis, content of water etc.) according to the current specifications.

2.2.41. CIRCULAR DICHROISM

The difference in absorbance of optically active substances within an absorption band for left and right circularly polarised light is referred to as circular dichroism.

Direct measurement gives a mean algebraic value:

$$\Delta A = A_{\mathrm{L}} - A_{\mathrm{R}}$$

ΔA = circular dichroic absorbance,

A_{L} = absorbance of left circularly polarised light,

A_{R} = absorbance of right circularly polarised light.

Circular dichroism is calculated using the equation:

$$\Delta\varepsilon = \varepsilon_{\mathrm{L}} - \varepsilon_{\mathrm{R}} = \frac{\Delta A}{c \times l}$$

$\Delta\epsilon$ = molar circular dichroism or molar differential dichroic absorptivity expressed in litre·mole^{-1}·cm^{-1},

ϵ_{L} = molar absorptivity (*2.2.25*) of left circularly polarised light,

ϵ_{R} = molar absorptivity of right circularly polarised light,

c = concentration of the test solution in mole·litre^{-1},

l = optical path of the cell in centimetres.

The following units may also be used to characterise circular dichroism:

Dissymmetry factor:

$$g = \frac{\Delta\varepsilon}{\varepsilon}$$

ϵ = molar absorptivity (*2.2.25*).

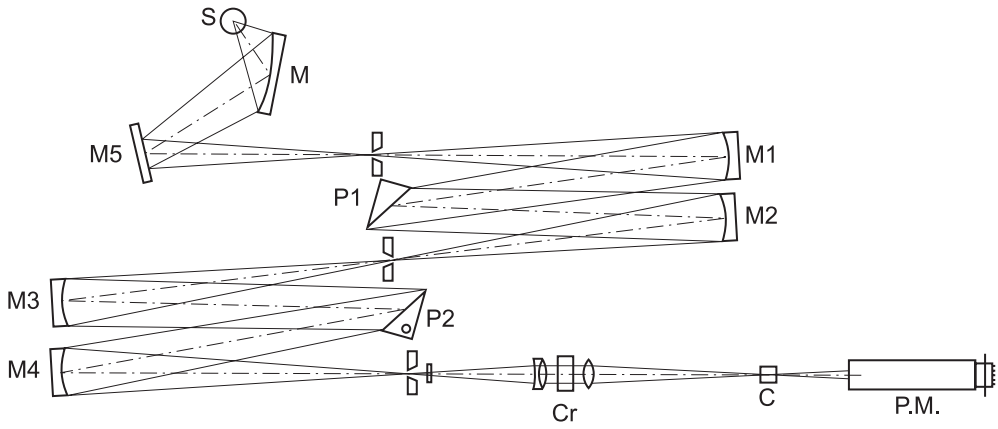

Figure 2.2.41.-1. – *Optical scheme of a dichrograph*

Molar ellipticity:

Certain types of instruments display directly the value of ellipticity Θ, expressed in degrees. When such instruments are used, the molar ellipticity [Θ] may be calculated using the following equation:

$$[\Theta] = \frac{\Theta \times M}{c \times l \times 10}$$

[Θ] = molar ellipticity, expressed in degrees·cm^2·decimole^{-1},

Θ = value of ellipticity given by the instrument,

M = relative molecular mass of the substance to be examined,

c = concentration of the solution to be examined in g/ml,

l = optical path of the cell in centimetres.

Molar ellipticity is also related to molar circular dichroism by the following equation:

$$[\Theta] = 2.303\Delta\varepsilon\frac{4500}{\pi} \approx 3300\Delta\varepsilon$$

Molar ellipticity is often used in the analysis of proteins and nucleic acids. In this case, molar concentration is expressed in terms of monomeric residue, calculated using the expression:

$$\frac{\text{molecular mass}}{\text{number of amino acids}}$$

The mean relative molecular mass of the monomeric residue is 100 to 120 (generally 115) for proteins and about 330 for nucleic acids (as the sodium salt).

Apparatus. The light source (S) is a xenon lamp (Figure 2.2.41.-1); the light passes through a double monochromator (M) equipped with quartz prisms (P1, P2).

The linear beam from the first monochromator is split into 2 components polarised at right angles in the second monochromator. The exit slit of the monochromator eliminates the extraordinary beam.

The polarised and monochromatic light passes through a birefringent modulator (Cr): the result is alternating circularly polarised light.

The beam then passes through the sample to be examined (C) and reaches a photomultiplier (PM) followed by an amplifier circuit which produces 2 electrical signals: one is a direct current V_c and the other is an alternating current at the modulation frequency V_{ac} characteristic of the sample to be examined. The phase gives the sign of the circular dichroism.

The ratio V_{ac}/V_c is proportional to the differential absorption ΔA which created the signal. The region of wavelengths normally covered by a dichrograph is 170 nm to 800 nm.

Calibration of the apparatus

Accuracy of absorbance scale. Dissolve 10.0 mg of *isoandrosterone R* in *dioxan R* and dilute to 10.0 ml with the same solvent. Record the circular dichroism spectrum of the solution between 280 nm and 360 nm. Measured at the maximum at 304 nm, $\Delta\epsilon$ is + 3.3.

The solution of *(1S)-(+)-10-camphorsulphonic acid R* may also be used.

Linearity of modulation. Dissolve 10.0 mg of *(1S)-(+)-10-camphorsulphonic acid R* in *water R* and dilute to 10.0 ml with the same solvent. Determine the exact concentration of camphorsulphonic acid in the solution by ultraviolet spectrophotometry (*2.2.25*), taking the specific absorbance to be 1.49 at 285 nm.

Record the circular dichroism spectrum between 185 nm and 340 nm. Measured at the maximum at 290.5 nm, $\Delta\epsilon$ is + 2.2 to + 2.5. Measured at the maximum at 192.5 nm, $\Delta\epsilon$ is – 4.3 to – 5.

(1S)-(+)- or antipodal *(1R)-(−)-ammonium 10-camphorsulphonate R* can also be used.

01/2008:20242

2.2.42. DENSITY OF SOLIDS

The density of solids corresponds to their average mass per unit volume and typically is expressed in grams per cubic centimetre (g/cm^3) although the International Unit is the kilogram per cubic meter (1 g/cm^3 = 1000 kg/m^3).

Unlike gases and liquids whose density depends only on temperature and pressure, the density of a solid particle also depends on its molecular assembly and therefore varies with the crystal structure and degree of crystallinity.

When a solid particle is amorphous or partially amorphous, its density may further depend upon the history of preparation and treatment.

Therefore, unlike fluids, the densities of two chemically equivalent solids may be different, and this difference reflects a difference in solid-state structure. The density of constituent particles is an important physical characteristic of pharmaceutical powders.

The density of a solid particle can assume different values depending on the method used to measure the volume of the particle. It is useful to distinguish three levels of expression of density:

– the *crystal density* which only includes the solid fraction of the material; the crystal density is also called *true density*;
– the *particle density* which also includes the volume due to intraparticulate pores,
– the *bulk density* which further includes the interparticulate void volume formed in the powder bed; the bulk density is also called *apparent density*.

CRYSTAL DENSITY

The crystal density of a substance is the average mass per unit volume, exclusive of all voids that are not a fundamental part of the molecular packing arrangement. It is an intrinsic property of the substance, and hence should be independent of the method of determination. The crystal density can be determined either by calculation or by simple measurement.

A. The *calculated crystal density* is obtained using crystallographic data (size and composition of the unit cell) of a perfect crystal, from for example X-ray diffraction data, and the molecular mass of the substance.
B. The *measured crystal density* is the mass to volume ratio after measuring the monocrystal mass and volume.

PARTICLE DENSITY

The particle density takes into account both the crystal density and the intraparticulate porosity (sealed and/or open pores). Thus, particle density depends on the value of the volume determined which in turn depends on the method of measurement. The particle density can be determined using one of the two following methods.

A. The *pycnometric density* is determined by measuring the volume occupied by a known mass of powder which is equivalent to the volume of gas displaced by the powder using a gas displacement pycnometer (*2.9.23*). In pycnometric density measurements, the volume determined includes the volume occupied by open pores; however, it excludes the volume occupied by sealed pores or pores inaccessible to the gas. Due to the high diffusivity of helium, which is the preferred choice of gas, most open pores are accessible to the gas. Therefore, the pycnometric density of a finely milled powder is generally not very different from the crystal density.
B. The *mercury porosimeter density* is also called *granular density*. With this method the volume determined also excludes contributions from sealed pores; however, it includes the volume only from open pores larger than some size limit. This pore size limit or minimal access diameter depends on the maximal mercury intrusion pressure applied during the measurement and under normal operating pressures the mercury does not penetrate the finest pores accessible to helium. Various granular densities can be obtained from one sample since, for each applied mercury intrusion pressure, a density can be determined that corresponds to the pore size limit at that pressure.

BULK AND TAPPED DENSITY

The bulk density of a powder includes the contribution of interparticulate void volume. Hence, the bulk density depends on both the density of powder particles and the space arrangement of particles in the powder bed.

The bulk density of a powder is often very difficult to measure since the slightest disturbance of the bed may result in a new density. Thus, it is essential in reporting bulk density to specify how the determination was made.

A. The *bulk density* is determined by measuring the volume of a known mass of powder, that has been passed through a screen, into a graduated cylinder (*2.9.15*).
B. The *tapped density* is achieved by mechanically tapping a measuring cylinder containing a powder sample. After observing the initial volume, the cylinder is mechanically tapped, and volume readings are taken until little further volume change is observed (*2.9.15*).

01/2008:20243

2.2.43. MASS SPECTROMETRY

Mass spectrometry is based on the direct measurement of the ratio of the mass to the number of positive or negative elementary charges of ions (m/z) in the gas phase obtained from the substance to be analysed. This ratio is expressed in atomic mass units (1 a.m.u. = one twelfth the mass of ^{12}C) or in daltons (1 Da = the mass of the hydrogen atom).

The ions, produced in the ion *source* of the apparatus, are accelerated and then separated by the *analyser* before reaching the *detector*. All of these operations take place in a chamber where a pumping system maintains a vacuum of 10^{-3} to 10^{-6} Pa.

The resulting spectrum shows the relative abundance of the various ionic species present as a function of m/z. The signal corresponding to an ion will be represented by several peaks corresponding to the statistical distribution of the various isotopes of that ion. This pattern is called the *isotopic profile* and (at least for small molecules) the peak representing the most abundant isotopes for each atom is called the *monoisotopic peak*.

Information obtained in mass spectrometry is essentially qualitative (determination of the molecular mass, information on the structure from the fragments observed) or quantitative (using internal or external standards) with limits of detection ranging from the picomole to the femtomole.

INTRODUCTION OF THE SAMPLE

The very first step of an analysis is the introduction of the sample into the apparatus without overly disturbing the vacuum. In a common method, called *direct liquid introduction*, the sample is placed on the end of a cylindrical rod (in a quartz crucible, on a filament or on a metal surface). This rod is introduced into the spectrometer after passing through a vacuum lock where a primary intermediate vacuum is maintained between atmospheric pressure and the secondary vacuum of the apparatus.

Other introduction systems allow the components of a mixture to be analysed as they are separated by an appropriate apparatus connected to the mass spectrometer.

Gas chromatography/mass spectrometry. The use of suitable columns (capillary or semi-capillary) allows the end of the column to be introduced directly into the source of the apparatus without using a separator.

Liquid chromatography/mass spectrometry. This combination is particularly useful for the analysis of polar compounds, which are insufficiently volatile or too heat-labile to be analysed by gas chromatography coupled with mass spectrometry. This method is complicated by the difficulty of obtaining ions in the gas phase from a liquid phase, which requires very special interfaces such as:

– *direct liquid introduction*: the mobile phase is nebulised, and the solvent is evaporated in front of the ion source of the apparatus,

– *particle-beam interface*: the mobile phase, which may flow at a rate of up to 0.6 ml/min, is nebulised in a desolvation chamber such that only the analytes, in neutral form, reach the ion source of the apparatus; this technique is used for compounds of relatively low polarity with molecular masses of less than 1000 Da,
– *moving-belt interface*: the mobile phase, which may flow at a rate of up to 1 ml/min, is applied to the surface of a moving belt; after the solvent evaporates, the components to be analysed are successively carried to the ion source of the apparatus where they are ionised; this technique is rather poorly suited to very polar or heat-labile compounds.

Other types of coupling (electrospray, thermospray, atmospheric-pressure chemical ionisation) are considered to be ionisation techniques in their own right and are described in the section on modes of ionisation.

Supercritical fluid chromatography/mass spectrometry. The mobile phase, usually consisting of supercritical carbon dioxide enters the gas state after passing a heated restrictor between the column and the ion source.

Capillary electrophoresis/mass spectrometry. The eluent is introduced into the ion source, in some cases after adding another solvent so that flow rates of the order of a few microlitres per minute can be attained. This technique is limited by the small quantities of sample introduced and the need to use volatile buffers.

MODES OF IONISATION

Electron impact. The sample, in the gas state, is ionised by a beam of electrons whose energy (usually 70 eV) is greater than the ionisation energy of the sample. In addition to the molecular ion M^+, fragments characteristic of the molecular structure are observed. This technique is limited mainly by the need to vaporise the sample. This makes it unsuited to polar, heat-labile or high molecular mass compounds. Electron impact is compatible with the coupling of gas chromatography to mass spectrometry and sometimes with the use of liquid chromatography.

Chemical ionisation. This type of ionisation involves a reagent gas such as methane, ammonia, nitrogen oxide, nitrogen dioxide or oxygen. The spectrum is characterised by ions of the $(M + H)^+$ or $(M - H)^-$ types, or adduct ions formed from the analyte and the gas used. Fewer fragments are produced than with electron impact. A variant of this technique is used when the substance is heat-labile: the sample, applied to a filament, is very rapidly vaporised by the Joule-Thomson effect (desorption chemical ionisation).

Fast-atom bombardment (FAB) or fast-ion bombardment ionisation (liquid secondary-ion mass spectrometry LSIMS). The sample, dissolved in a viscous matrix such as glycerol, is applied to a metal surface and ionised by a beam of neutral atoms such as argon or xenon or high-kinetic-energy caesium ions. Ions of the $(M + H)^+$ or $(M - H)^-$ types or adduct ions formed from the matrix or the sample are produced. This type of ionisation, well suited to polar and heat-labile compounds, allows molecular masses of up to 10 000 Da to be obtained. The technique can be combined with liquid chromatography by adding 1 per cent to 2 per cent of glycerol to the mobile phase; however, the flow rates must be very low (a few microlitres per minute). These ionisation techniques also allow thin-layer chromatography plates to be analysed by applying a thin layer of matrix to the surface of these plates.

Field desorption and field ionisation. The sample is vaporised near a tungsten filament covered with microneedles (*field ionisation*) or applied to this filament (*field desorption*). A voltage of about 10 kV, applied between this filament and a counter-electrode, ionises the sample. These two techniques mainly produce molecular ions M^+, and $(M + H)^+$ ions and are used for low polarity and/or heat-labile compounds.

Matrix-assisted laser desorption ionisation (MALDI). The sample, in a suitable matrix and deposited on a metal support, is ionised by a pulsed laser beam whose wavelength may range from UV to IR (impulses lasting from a picosecond to a few nanoseconds). This mode of ionisation plays an essential role in the analysis of very high molecular mass compounds (more than 100 000 Da) but is limited to time-of flight analysers (see below).

Electrospray. This mode of ionisation is carried out at atmospheric pressure. The samples, in solution, are introduced into the source through a capillary tube, the end of which has a potential of the order of 5 kV. A gas can be used to facilitate nebulisation. Desolvation of the resulting microdroplets produces singly or multiply charged ions in the gas phase. The flow rates vary from a few microlitres per minute to 1 ml/min. This technique is suited to polar compounds and to the investigation of biomolecules with molecular masses of up to 100 000 Da. It can be coupled to liquid chromatography or capillary electrophoresis.

Atmospheric-pressure chemical ionisation (APCI). Ionisation is carried out at atmospheric pressure by the action of an electrode maintained at a potential of several kilovolts and placed in the path of the mobile phase, which is nebulised both by thermal effects and by the use of a stream of nitrogen. The resulting ions carry a single charge and are of the $(M + H)^+$ type in the positive mode and of the $(M - H)^-$ type in the negative mode. The high flow rates that can be used with this mode of ionisation (up to 2 ml/min) make this an ideal technique for coupling to liquid chromatography.

Thermospray. The sample, in the mobile phase consisting of water and organic modifiers and containing a volatile electrolyte (generally ammonium acetate) is introduced in nebulised form after having passed through a metal capillary tube at controlled temperature. Acceptable flow rates are of the order of 1 ml/min to 2 ml/min. The ions of the electrolyte ionise the compounds to be analysed. This ionisation process may be replaced or enhanced by an electrical discharge of about 800 volts, notably when the solvents are entirely organic. This technique is compatible with the use of liquid chromatography coupled with mass spectrometry.

ANALYSERS

Differences in the performance of analysers depend mainly on two parameters:

– the range over which m/z ratios can be measured, ie, the *mass range*,
– their *resolving power* characterised by the ability to separate two ions of equal intensity with m/z ratios differing by ΔM, and whose overlap is expressed as a given percentage of valley definition; for example, a resolving power ($M/\Delta M$) of 1000 with 10 per cent valley definition allows the separation of m/z ratios of 1000 and 1001 with the intensity returning to 10 per cent above baseline. However, the resolving power may in some cases (time-of-flight analysers, quadrupoles, ion-trap analysers) be defined as the ratio between the molecular mass and peak width at half height (50 per cent valley definition).

Magnetic and electrostatic analysers. The ions produced in the ion source are accelerated by a voltage V, and focused towards a magnetic analyser (magnetic field B) or an

electrostatic analyser (electrostatic field E), depending on the configuration of the instrument. They follow a trajectory of radius r according to Laplace's law:

$$\frac{m}{z} = \frac{B^2 r^2}{2V}$$

Two types of scans can be used to collect and measure the various ions produced by the ion source: a scan of B holding V fixed or a scan of V with constant B. The magnetic analyser is usually followed by an electric sector that acts as a kinetic energy filter and allows the resolving power of the instrument to be increased appreciably. The maximum resolving power of such an instrument (double sector) ranges from 10 000 to 150 000 and in most cases allows the value of m/z ratios to be calculated accurately enough to determine the elemental composition of the corresponding ions. For monocharged ions, the mass range is from 2000 Da to 15 000 Da. Some ions may decompose spontaneously (metastable transitions) or by colliding with a gas (collision-activated dissociation (CAD)) in field-free regions between the ion source and the detector. Examination of these decompositions is very useful for the determination of the structure as well as the characterisation of a specific compound in a mixture and involves tandem mass spectrometry. There are many such techniques depending on the region where these decompositions occur:

- *daughter-ion mode* (determination of the decomposition ions of a given parent ion): B/E = constant, *MIKES (Mass-analysed Ion Kinetic Energy Spectroscopy),*
- *parent-ion mode* (determination of all ions which by decomposition give an ion with a specific m/z ratio): B^2/E = constant,
- *neutral-loss mode* (detection of all the ions that lose the same fragment):

  $B/E(1 - E/E_0)^{1/2}$ = constant, where E_0 is the basic voltage of the electric sector.

Quadrupoles. The analyser consists of four parallel metal rods, which are cylindrical or hyperbolic in cross-section. They are arranged symmetrically with respect to the trajectory of the ions; the pairs diagonally opposed about the axis of symmetry of rods are connected electrically. The potentials to the two pairs of rods are opposed. They are the resultant of a constant component and an alternating component. The ions produced at the ion source are transmitted and separated by varying the voltages applied to the rods so that the ratio of continuous voltage to alternating voltage remains constant. The quadrupoles usually have a mass range of 1 a.m.u. to 2000 a.m.u., but some may range up to 4000 a.m.u. Although they have a lower resolving power than magnetic sector analysers, they nevertheless allow the monoisotopic profile of single charged ions to be obtained for the entire mass range. It is possible to obtain spectra using three quadrupoles arranged in series, Q_1, Q_2, Q_3 (Q_2 serves as a collision cell and is not really an analyser; the most commonly used collision gas is argon).

The most common types of scans are the following:

- *daughter-ion mode*: Q_1 selects an m/z ion whose fragments obtained by collision in Q_2 are analysed by Q_3,
- *parent-ion mode*: Q_3 filters only a specific m/z ratio, while Q_1 scans a given mass range. Only the ions decomposing to give the ion selected by Q_3 are detected,
- *neutral loss mode*: Q_1 and Q_3 scan a certain mass range but at an offset corresponding to the loss of a fragment characteristic of a product or family of compounds.

It is also possible to obtain spectra by combining quadrupole analysers with magnetic or electrostatic sector instruments; such instruments are called *hybrid mass spectrometers.*

Ion-trap analyser. The principle is the same as for a quadrupole, this time with the electric fields in three dimensions. This type of analyser allows product-ion spectra over several generations (MS^n) to be obtained.

Ion-cyclotron resonance analysers. Ions produced in a cell and subjected to a uniform, intense magnetic field move in circular orbits at frequencies which can be directly correlated to their m/z ratio by applying a Fourier transform algorithm. This phenomenon is called ion-cyclotron resonance. Analysers of this type consist of superconducting magnets and are capable of very high resolving power (up to 1000 000 and more) as well as MS^n spectra. However, very low pressures are required (of the order of 10^{-7} Pa).

Time-of-flight analysers. The ions produced at the ion source are accelerated at a voltage V of 10 kV to 20 kV. They pass through the analyser, consisting of a field-free tube, 25 cm to 1.5 m long, generally called a *flight tube.* The time (t) for an ion to travel to the detector is proportional to the square root of the m/z ratio. Theoretically the mass range of such an analyser is infinite. In practice, it is limited by the ionisation or desorption method. Time-of-flight analysers are mainly used for high molecular mass compounds (up to several hundred thousand daltons). This technique is very sensitive (a few picomoles of product are sufficient). The accuracy of the measurements and the resolving power of such instruments may be improved considerably by using an electrostatic mirror (reflectron).

SIGNAL ACQUISITION

There are essentially three possible modes.

Complete spectrum mode. The entire signal obtained over a chosen mass range is recorded. The spectrum represents the relative intensity of the different ionic species present as a function of m/z. The results are essentially qualitative. The use of spectral reference libraries for more rapid identification is possible.

Fragmentometric mode (Selected-ion monitoring). The acquired signal is limited to one (single-ion monitoring (SIM)) or several (multiple-ion monitoring (MIM)) ions characteristic of the substance to be analysed. The limit of detection can be considerably reduced in this mode. Quantitative or semiquantitative tests can be carried out using external or internal standards (for example, deuterated standards). Such tests cannot be carried out with time-of-flight analysers.

Fragmentometric double mass spectrometry mode (multiple reaction monitoring (MRM)). The unimolecular or bimolecular decomposition of a chosen precursor ion characteristic of the substance to be analysed is followed specifically. The selectivity and the highly specific nature of this mode of acquisition provide excellent sensitivity levels and make it the most appropriate for quantitative studies using suitable internal standards (for example, deuterated standards). This type of analysis can be performed only on apparatus fitted with three quadrupoles in series, ion-trap analysers or cyclotron-resonance analysers.

CALIBRATION

Calibration allows the corresponding m/z value to be attributed to the detected signal. As a general rule, this is done using a reference substance. This calibration may be external (acquisition file separate from the analysis) or internal (the reference substance(s) are mixed with the substance to be examined and appear on the same acquisition file). The number of ions or points required for reliable calibration depends on the type of analyser and on the desired accuracy of the measurement, for example, in

the case of a magnetic analyser where the *m/z* ratio varies exponentially with the value of the magnetic field, there should be as many points as possible.

SIGNAL DETECTION AND DATA PROCESSING

Ions separated by an analyser are converted into electric signals by a detection system such as a photomultiplier or an electron multiplier. These signals are amplified before being re-converted into digital signals for data processing, allowing various functions such as calibration, reconstruction of spectra, automatic quantification, archiving, creation or use of libraries of mass spectra. The various physical parameters required for the functioning of the apparatus as a whole are controlled by computer.

2.2.44. TOTAL ORGANIC CARBON IN WATER FOR PHARMACEUTICAL USE

Total organic carbon (TOC) determination is an indirect measure of organic substances present in water for pharmaceutical use. TOC determination can also be used to monitor the performance of various operations in the preparation of medicines.

A variety of acceptable methods is available for determining TOC. Rather than prescribing a given method to be used, this general chapter describes the procedures used to qualify the chosen method and the interpretation of results in limit tests. A standard solution is analysed at suitable intervals, depending on the frequency of measurements; the solution is prepared with a substance that is expected to be easily oxidisable (for example, sucrose) at a concentration adjusted to give an instrument response corresponding to the TOC limit to be measured. The suitability of the system is determined by analysis of a solution prepared with a substance expected to be oxidisable with difficulty (for example, 1,4-benzoquinone).

The various types of apparatus used to measure TOC in water for pharmaceutical use have in common the objective of completely oxidising the organic molecules in the sample water to produce carbon dioxide followed by measurement of the amount of carbon dioxide produced, the result being used to calculate the carbon concentration in the water.

The apparatus used must discriminate between organic and inorganic carbon, the latter being present as carbonate. The discrimination may be effected either by measuring the inorganic carbon and subtracting it from the total carbon, or by purging inorganic carbon from the sample before oxidisation. Purging may also entrain organic molecules, but such purgeable organic carbon is present in negligible quantities in water for pharmaceutical use.

Apparatus. Use a calibrated instrument installed either on-line or off-line. Verify the system suitability at suitable intervals as described below. The apparatus must have a limit of detection specified by the manufacturer of 0.05 mg or less of carbon per litre.

TOC water. Use highly purified water complying with the following specifications:

– conductivity: not greater than 1.0 $\mu S \cdot cm^{-1}$ at 25 °C,

– total organic carbon: not greater than 0.1 mg/l.

Depending on the type of apparatus used, the content of heavy metals and copper may be critical. The manufacturer's instructions should be followed.

Glassware preparation. Use glassware that has been scrupulously cleaned by a method that will remove organic matter. Use *TOC water* for the final rinse of glassware.

Standard solution. Dissolve *sucrose R*, dried at 105 °C for 3 h in *TOC water* to obtain a solution containing 1.19 mg of sucrose per litre (0.50 mg of carbon per litre).

Test solution. Using all due care to avoid contamination, collect water to be tested in an airtight container leaving minimal head-space. Examine the water with minimum delay to reduce contamination from the container and its closure.

System suitability solution. Dissolve *1,4-benzoquinone R* in *TOC water* to obtain a solution having a concentration of 0.75 mg of 1,4-benzoquinone per litre (0.50 mg of carbon per litre).

TOC water control. Use *TOC water* obtained at the same time as that used to prepare the standard solution and the system suitability solution.

Control solutions. In addition to the *TOC water control*, prepare suitable blank solutions or other solutions needed for establishing the baseline or for calibration adjustments following the manufacturer's instructions; run the appropriate blanks to zero the instrument.

System suitability. Run the following solutions and record the responses: *TOC water* (r_w); *standard solution* (r_s); *system suitability solution* (r_{ss}). Calculate the percentage response efficiency using the expression:

$$\frac{r_{ss} - r_w}{r_s - r_w} \times 100$$

The system is suitable if the response efficiency is not less than 85 per cent and not more than 115 per cent of the theoretical response.

Procedure. Run the test solution and record the response (r_u). The test solution complies with the test if r_u is not greater than $r_s - r_w$.

The method can also be applied using on-line instrumentation that has been adequately calibrated and shown to have acceptable system suitability. The location of instrumentation must be chosen to ensure that the responses are representative of the water used.

01/2008:20245

2.2.45. SUPERCRITICAL FLUID CHROMATOGRAPHY

Supercritical fluid chromatography (SFC) is a method of chromatographic separation in which the mobile phase is a fluid in a supercritical or a subcritical state. The stationary phase, contained in a column, consists of either finely divided solid particles, such as a silica or porous graphite, a chemically modified stationary phase, as used in liquid chromatography, or, for capillary columns, a cross-linked liquid film evenly coated on the walls of the column.

SFC is based on mechanisms of adsorption or mass distribution.

APPARATUS

The apparatus usually consists of a cooled pumping system, an injector, a chromatographic column, contained in an oven, a detector, a pressure regulator and a data acquisition device (or an integrator or a chart recorder).

Pumping system

Pumping systems are required to deliver the mobile phase at a constant flow rate. Pressure fluctuations are to be

minimised, e.g. by passing the pressurised solvent through a pulse-damping device. Tubing and connections are capable of withstanding the pressures developed by the pumping system.

Microprocessor controlled systems are capable of accurately delivering a mobile phase in either constant or varying conditions, according to a defined programme. In the case of gradient elution, pumping systems which deliver solvent(s) from several reservoirs are available and solvent mixing can be achieved on either the low or high-pressure side of the pump(s).

Injectors

Injection may be carried out directly at the head of the column using a valve.

Stationary phases

Stationary phases are contained in columns which have been described in the chapters on *Liquid chromatography* (*2.2.29*) (packed columns) and *Gas chromatography* (*2.2.28*) (capillary columns). A capillary column has a maximum internal diameter (Ø) of 100 µm.

Mobile phases

Usually the mobile phase is carbon-dioxide which may contain a polar modifier such as methanol, 2-propanol or acetonitrile. The composition, pressure (density), temperature and flow rate of the prescribed mobile phase may either be constant throughout the whole chromatographic procedure (isocratic, isodense, isothermic elution) or may vary according to a defined programme (gradient elution of the modifier, pressure (density), temperature or flow rate).

Detectors

Ultraviolet/visible (UV/Vis) spectrophotometers and flame ionisation detectors are the most commonly employed detectors. Light scattering detectors, infrared absorption spectrophotometers, thermal conductivity detectors or other special detectors may be used.

METHOD

Prepare the test solution(s) and the reference solution(s) as prescribed. The solutions must be free from solid particles.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (*2.2.46*). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

01/2008:20246

2.2.46. CHROMATOGRAPHIC SEPARATION TECHNIQUES

Chromatographic separation techniques are multi-stage separation methods in which the components of a sample are distributed between 2 phases, one of which is stationary, while the other is mobile. The stationary phase may be a solid or a liquid supported on a solid or a gel. The stationary phase may be packed in a column, spread as a layer, or distributed as a film, etc. The mobile phase may be gaseous or liquid or supercritical fluid. The separation may be based on adsorption, mass distribution (partition), ion exchange, etc., or may be based on differences in the physico-chemical properties of the molecules such as size, mass, volume, etc.

This chapter contains definitions and calculations of common parameters and generally applicable requirements for system suitability. Principles of separation, apparatus and methods are given in the following general methods:

- paper chromatography (*2.2.26*),
- thin-layer chromatography (*2.2.27*),
- gas chromatography (*2.2.28*),
- liquid chromatography (*2.2.29*),
- size-exclusion chromatography (*2.2.30*),
- supercritical fluid chromatography (*2.2.45*).

DEFINITIONS

The following definitions have been used to calculate the limits in monographs.

With some equipment, certain parameters, such as the signal-to-noise ratio, can be calculated using software provided by the manufacturer. It is the responsibility of the user to ensure that the calculation methods used in the software are compatible with the requirements of the European Pharmacopoeia. If not, the necessary corrections must be made.

Chromatogram

A chromatogram is a graphical or other representation of detector response, effluent concentration or other quantity used as a measure of effluent concentration, versus time, volume or distance. Idealised chromatograms are represented as a sequence of gaussian peaks on a baseline.

RETENTION DATA

Retention time and retention volume

Retention measurements in elution chromatography may be given as the retention time (t_R) directly defined by the position of the maximum of the peak in the chromatogram. From the retention time, the retention volume (V_R) may be calculated.

$$V_R = v \times t_R$$

t_R = retention time or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,

v = flow rate of the mobile phase.

Mass distribution ratio

The mass distribution ratio (D_m) (also known as the capacity factor *k'* or retention factor k) is defined as:

$$D_m = \frac{\text{amount of solute in stationary phase}}{\text{amount of solute in mobile phase}} = K_C \frac{V_S}{V_M}$$

K_C = equilibrium distribution coefficient (also known as distribution constant),

V_S = volume of the stationary phase,

V_M = volume of the mobile phase.

The mass distribution ratio of a component may be determined from the chromatogram using the expression:

$$D_m = \frac{t_R - t_M}{t_M}$$

t_R = retention time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,

t_M = hold-up time (or volume): time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to an unretained component.

Distribution coefficient

The elution characteristics of a component in a particular column, in size-exclusion chromatography, may be given by the distribution coefficient (K_o) which is calculated from the expression:

$$K_o = \frac{t_R - t_o}{t_t - t_o}$$

t_R = retention time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,

t_o = hold-up time (or volume): time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to an unretained component,

t_t = retention time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to a component which has full access to the pores of the stationary phase.

Retardation factor

The retardation factor (R_F) (also known as retention factor R_f), used in planar chromatography, is the ratio of the distance from the point of application to the centre of the spot and the distance travelled by the solvent front from the point of application.

$$R_F = \frac{b}{a}$$

b = migration distance of the analyte,

a = migration distance of the solvent front.

CHROMATOGRAPHIC DATA

The peak may be defined by the *peak area (A)* or the *peak height (h)* and the *peak width at half- height (w_h)* or the *peak height (h)* and the *peak width between the points of inflection (w_i).* In gaussian peaks (Figure 2.2.46.-1) there is the relationship:

$$w_h = 1.18 w_i$$

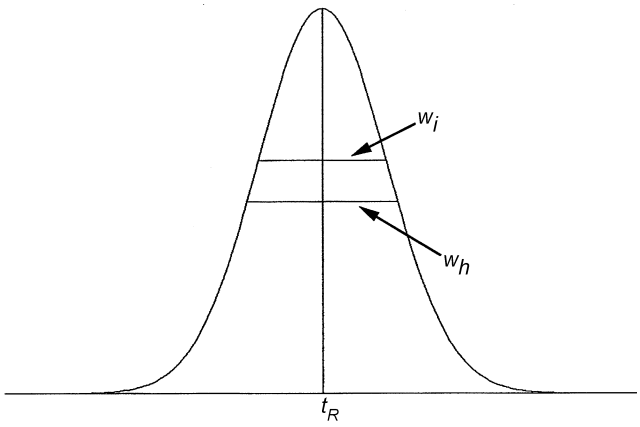

Figure 2.2.46.-1.

Symmetry factor

The symmetry factor (A_s) (or tailing factor) of a peak (Figure 2.2.46.-2) is calculated from the expression:

$$A_s = \frac{w_{0.05}}{2d}$$

$w_{0.05}$ = width of the peak at one-twentieth of the peak height,

d = distance between the perpendicular dropped from the peak maximum and the leading edge of the peak at one-twentieth of the peak height.

A value of 1.0 signifies complete (ideal) symmetry.

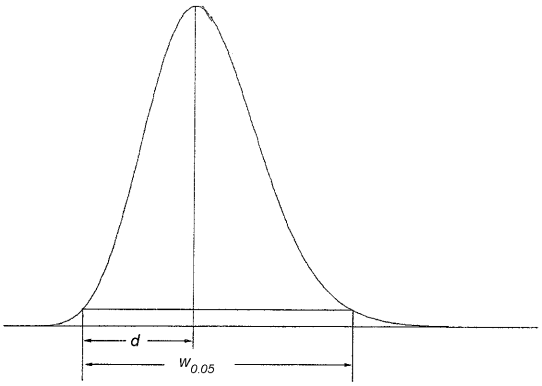

Figure 2.2.46.-2.

Column performance and apparent number of theoretical plates

The column performance (apparent efficiency) may be calculated from data obtained under either isothermal, isocratic or isodense conditions, depending on the technique, as the apparent number of theoretical plates (N) from the following expression, where the values of t_R and w_h have to be expressed in the same units (time, volume or distance).

$$N = 5.54 \left(\frac{t_R}{w_h} \right)^2$$

t_R = retention time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,

w_h = width of the peak at half-height.

The apparent number of theoretical plates varies with the component as well as with the column and the retention time.

SEPARATION DATA

Resolution

The resolution (R_s) between peaks of 2 components may be calculated from the expression:

$$R_s = \frac{1.18\,(t_{R2} - t_{R1})}{w_{h1} + w_{h2}}$$

$$t_{R2} > t_{R1}$$

t_{R1} and t_{R2} = retention times or distances along the baseline from the point of injection to the perpendiculars dropped from the maxima of 2 adjacent peaks,

w_{h1} and w_{h2} = peak widths at half-height.

A resolution of greater than 1.5 corresponds to baseline separation.

The expression given above may not be applicable if the peaks are not baseline separated.

In quantitative planar chromatography, the migration distances are used instead of retention times and the resolution may be calculated using the expression:

$$R_s = \frac{1.18\,a\,(R_{F2} - R_{F1})}{w_{h1} + w_{h2}}$$

R_{F1} and R_{F2} = ratios of the distances from the point of application to the centres of the spots and the distance travelled by the solvent front from the point of application (retardation factor),

w_{h1} and w_{h2} = peak widths at half-height,

a = migration distance of the solvent front.

Peak-to-valley ratio

The peak-to-valley ratio (p/v) may be employed as a system suitability requirement in a test for related substances when baseline separation between 2 peaks is not reached (Figure 2.2.46.-3).

$$p/v = \frac{H_p}{H_v}$$

H_p = height above the extrapolated baseline of the minor peak,

H_v = height above the extrapolated baseline at the lowest point of the curve separating the minor and major peaks.

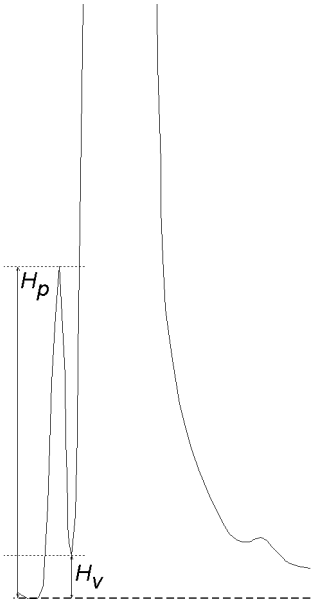

Figure 2.2.46.-3.

Relative retention

The relative retention (r) is calculated as an estimate from the expression:

$$r = \frac{t_{R2} - t_M}{t_{R1} - t_M}$$

t_{R2} = retention time of the peak of interest,

t_{R1} = retention time of the reference peak (usually the peak corresponding to the substance to be examined),

t_M = hold-up time: time or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to an unretained component.

The unadjusted relative retention (r_G) is calculated from the expression:

$$r_G = \frac{t_{R2}}{t_{R1}}$$

Unless otherwise indicated, values for relative retention stated in monographs correspond to unadjusted relative retention.

In planar chromatography, the retardation factors R_{F2} and R_{F1} are used instead of t_{R2} and t_{R1}.

PRECISION OF QUANTIFICATION

Signal-to-noise ratio

The signal-to-noise ratio (*S/N*) influences the precision of quantification and is calculated from the equation:

$$S/N = \frac{2H}{h}$$

H = height of the peak (Figure 2.2.46.-4) corresponding to the component concerned, in the chromatogram obtained with the prescribed reference solution, measured from the maximum of the peak to the extrapolated baseline of the signal observed over a distance equal to 20 times the width at half-height,

h = range of the background noise in a chromatogram obtained after injection or application of a blank, observed over a distance equal to 20 times the width at half-height of the peak in the chromatogram obtained with the prescribed reference solution and, if possible, situated equally around the place where this peak would be found.

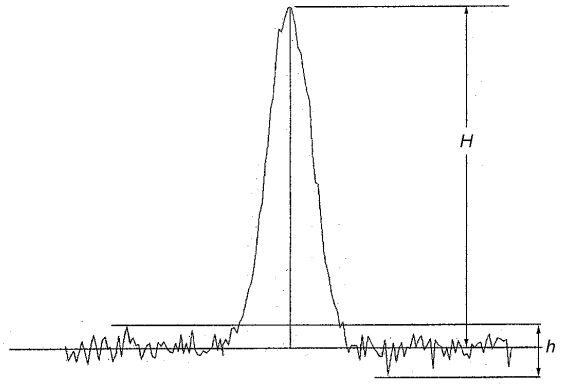

Figure 2.2.46.-4.

Repeatability

The repeatability of response is expressed as an estimated percentage relative standard deviation ($RSD_{\%}$) of a consecutive series of measurement of injections or applications of a reference solution and is calculated from the expression:

$$RSD_{\%} = \frac{100}{\bar{y}}\sqrt{\frac{\sum (y_i - \bar{y})^2}{n-1}}$$

y_i = individual values expressed as peak area, peak height, or ratio of areas by the internal standardisation method,

$\bar{y}$ = mean of individual values,

n = number of individual values.

The maximal permitted relative standard deviation (RSD_{max}) is calculated for a series of injections of the reference solution for defined limits using the following expression:

$$RSD_{\max} = \frac{K\mathrm{B}\sqrt{n}}{t_{90\%,n-1}}$$

K = constant (0.349), obtained from the expression $K = \frac{0.6}{\sqrt{2}} \times \frac{t_{90\%,5}}{\sqrt{6}}$ in which $\frac{0.6}{\sqrt{2}}$ represents the required *RSD* after 6 injections for B = 1.0,

B = upper limit given in the definition of the individual monograph minus 100 per cent,

n = number of replicate injections of the reference solution ($3 \leq n \leq 6$),

$t_{90\%,n-1}$ = Student's t at the 90 per cent probability level (double sided) with $n - 1$ degrees of freedom.

SYSTEM SUITABILITY

The system suitability tests represent an integral part of the method and are used to ensure adequate performance of the chromatographic system. Apparent efficiency, mass distribution ratio, resolution, relative retention and the symmetry factor are the parameters which are usually employed in assessing the performance of the column. Factors which may affect the chromatographic behaviour include the composition, ionic strength, temperature and apparent pH of the mobile phase, flow rate, column length, temperature and pressure, and stationary phase characteristics including porosity, particle size, type of particles, specific surface area and, in the case of reverse-phase supports, the extent of chemical modification (as expressed by end-capping, carbon loading etc.).
The various components of the equipment employed must be qualified and be capable of achieving the precision required to conduct the test or assay.

The following requirements are to be fulfilled unless otherwise stated in the monograph.

- The symmetry factor of the principal peak is to be between 0.8 and 1.5 unless otherwise stated in the monograph. This requirement has general applicability to tests or assays described in the monographs.
- Maximal permitted relative standard deviation for replicate injections of the prescribed reference solution do not exceed the values given in Table 2.2.46.-1. This requirement is applicable to assays for content only and does not apply to the test for related substances.
- The limit of detection of the peak (corresponding to a signal-to-noise ratio of 3) is below the disregard limit of the test for related substances.
- The limit of quantitation of the peak (corresponding to a signal-to-noise ratio of 10) is equal to or less than the disregard limit of the test for related substances.

Table 2.2.46.-1. – *Repeatability requirements*

	Number of individual injections			
	3	4	5	6
B (per cent)	Maximal permitted relative standard deviation			
2.0	0.41	0.59	0.73	0.85
2.5	0.52	0.74	0.92	1.06
3.0	0.62	0.89	1.10	1.27

ADJUSTMENT OF CHROMATOGRAPHIC CONDITIONS

The extent to which the various parameters of a chromatographic test may be adjusted to satisfy the system suitability criteria without fundamentally modifying the methods are listed below for information. The chromatographic conditions described have been validated during the elaboration of the monograph. The system suitability tests are included to ensure the separation required for satisfactory performance of the test or assay. Nonetheless, since the stationary phases are described in a general way and there is such a variety available

commercially, with differences in chromatographic behaviour, some adjustments of the chromatographic conditions may be necessary to achieve the prescribed system suitability requirements. With reverse-phase liquid chromatographic methods, in particular, adjustment of the various parameters will not always result in satisfactory chromatography. In that case, it may be necessary to replace the column with another of the same type (e.g. octadecylsilyl silica gel) which exhibits the desired chromatographic behaviour.

For critical parameters the adjustments are defined clearly in the monograph to ensure the system suitability.

Multiple adjustments which may have a cumulative effect in the performance of the system are to be avoided.

Thin-layer chromatography and paper chromatography

Composition of the mobile phase: the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger; for a minor component at 10 per cent of the mobile phase, a 30 per cent relative adjustment allows a range of 7-13 per cent whereas a 2 per cent absolute adjustment allows a range of 8-12 per cent, the relative value being therefore the larger; for a minor component at 5 per cent of the mobile phase, a 30 per cent relative adjustment allows a range of 3.5-6.5 per cent whereas a 2 per cent absolute adjustment allows a range of 3-7 per cent, the absolute value being in this case the larger. No other component is altered by more than 10 per cent absolute.

pH of the aqueous component of the mobile phase: ± 0.2 pH, unless otherwise stated in the monograph, or ± 1.0 pH when neutral substances are to be examined.

Concentration of salts in the buffer component of a mobile phase: ± 10 per cent.

Application volume: 10-20 per cent of the prescribed volume if using fine particle size plates (2-10 µm).

Migration distance of the solvent front is to be not less than 50 mm or 30 mm on high-performance plates.

Liquid chromatography

Composition of the mobile phase: the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger (see example above). No other component is altered by more than 10 per cent absolute.

pH of the aqueous component of the mobile phase: ± 0.2 pH, unless otherwise stated in the monograph, or ± 1.0 pH when neutral substances are to be examined.

Concentration of salts in the buffer component of a mobile phase: ± 10 per cent.

Detector wavelength: no adjustment permitted.

Stationary phase:

- *column length*: ± 70 per cent,
- *column internal diameter*: ± 25 per cent,
- *particle size*: maximal reduction of 50 per cent, no increase permitted.

Flow rate: ± 50 per cent. When in a monograph the retention time of the principle peak is indicated, the flow rate has to be adjusted if the column internal diameter has been changed. No decrease of flow rate is permitted if the monograph uses apparent number of theoretical plates in the qualification section.

Temperature: ± 10 per cent, to a maximum of 60 °C.

Injection volume: may be decreased, provided detection and repeatability of the peak(s) to be determined are satisfactory.

Gradient elution: the configuration of the equipment employed may significantly alter the resolution, retention time and relative retentions described in the method. Should this occur, it may be due to excessive dwell volume which is the volume between the point at which the 2 eluants meet and the top of the column.

Gas chromatography

Stationary phase:

- *column length*: ± 70 per cent,
- *column internal diameter*: ± 50 per cent,
- *particle size*: maximal reduction of 50 per cent, no increase permitted,
- *film thickness*: – 50 per cent to + 100 per cent.

Flow rate: ± 50 per cent.

Temperature: ± 10 per cent.

Injection volume: may be decreased, provided detection and repeatability are satisfactory.

Supercritical fluid chromatography

Composition of the mobile phase: for packed columns, the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger. No adjustment is permitted for a capillary column system.

Detector wavelength: no adjustment permitted.

Stationary phase:

- *column length*: ± 70 per cent,
- *column internal diameter*:

  ± 25 per cent (packed columns),

  ± 50 per cent (capillary columns),
- *particle size*: maximal reduction of 50 per cent, no increase permitted (packed columns).

Flow rate: ± 50 per cent.

Temperature: ± 10 per cent.

Injection volume: may be decreased, provided detection and repeatability are satisfactory.

QUANTIFICATION

- *Detector response.* The detector sensitivity is the signal output per unit concentration or unit mass of a substance in the mobile phase entering the detector. The relative detector response factor, commonly referred to as *response factor*, expresses the sensitivity of a detector relative to a standard substance. The *correction factor* is the reciprocal of the response factor.
- *External standard method.* The concentration of the component(s) to be analysed is determined by comparing the response(s) (peak(s)) obtained with the test solution to the response(s) (peak(s)) obtained with a reference solution.
- *Internal standard method.* Equal amounts of a component that is resolved from the substance to be examined (the internal standard) is introduced into the test solution and a reference solution. The internal standard should not react with the substance to be examined; it must be stable and must not contain impurities with a retention time similar to that of the substance to be examined. The concentration of the substance to be examined is determined by comparing the ratio of the peak areas or peak heights due to the substance to be examined and the internal standard in the test solution with the ratio of the peak areas or peak heights due to the substance to be examined and the internal standard in the reference solution.

– *Normalisation procedure.* The percentage content of one or more components of the substance to be examined is calculated by determining the area of the peak or peaks as a percentage of the total area of all the peaks, excluding those due to solvents or any added reagents and those below the disregard limit.

– *Calibration procedure.* The relationship between the measured or evaluated signal *(y)* and the amount (concentration, mass, etc.) of substance *(x)* is determined and the calibration function is calculated. The analytical results are calculated from the measured signal or evaluated signal of the analyte by means of the inverse function.

For assays and for quantitative determination of components the external standard method, the internal standard method or the calibration procedure may be described in the monograph, and the normalisation procedure is not normally applied. In tests for related substances, either the external standard method with a single reference solution or the normalisation procedure is generally applied. However, with both the normalisation procedure or the external standard method, when a dilution of the test solution is used for comparison, the responses of the related substances are similar to the substance itself (response factor of 0.8 to 1.2), otherwise correction factors are included in the text.

When the related substances test prescribes the summation of impurities or there is quantitative determination of an impurity, it is important to choose an appropriate threshold setting and appropriate conditions for the integration of the peak areas. In such tests the *disregard limit*, e.g. the areas of peaks whose areas are below the limit are not taken into account, is generally 0.05 per cent. Thus, the threshold setting of the data collection system corresponds to, at least, half of the disregard limit. Integration of the peak areas of the impurities, which are not completely separated from the main peak, are preferably performed by valley-to-valley extrapolation (tangential skim). Peaks due to the solvent(s) used to dissolve the sample are also to be disregarded.

01/2008:20247

2.2.47. CAPILLARY ELECTROPHORESIS

GENERAL PRINCIPLES

Capillary electrophoresis is a physical method of analysis based on the migration, inside a capillary, of charged analytes dissolved in an electrolyte solution, under the influence of a direct-current electric field.

The migration velocity of an analyte under an electric field of intensity *E*, is determined by the electrophoretic mobility of the analyte and the electro-osmotic mobility of the buffer inside the capillary. The electrophoretic mobility of a solute (μ_{ep}) depends on the characteristics of the solute (electric charge, molecular size and shape) and those of the buffer in which the migration takes place (type and ionic strength of the electrolyte, pH, viscosity and additives). The electrophoretic velocity (ν_{ep}) of a solute, assuming a spherical shape, is given by the equation:

$$\nu_{ep} = \mu_{ep} \times E = \left(\frac{q}{6\pi\eta r}\right) \times \left(\frac{V}{L}\right)$$

q = effective charge of the solute,

η = viscosity of the electrolyte solution,

r = Stoke's radius of the solute,

V = applied voltage,

L = total length of the capillary.

When an electric field is applied through the capillary filled with buffer, a flow of solvent is generated inside the capillary, called electro-osmotic flow. The velocity of the electro-osmotic flow depends on the electro-osmotic mobility (μ_{eo}) which in turn depends on the charge density on the capillary internal wall and the buffer characteristics. The electro-osmotic velocity (ν_{eo}) is given by the equation:

$$\nu_{eo} = \mu_{eo} \times E = \left(\frac{\varepsilon\zeta}{\eta}\right) \times \left(\frac{V}{L}\right)$$

ϵ = dielectric constant of the buffer,

ζ = zeta potential of the capillary surface.

The velocity of the solute (ν) is given by:

$$\nu = \nu_{ep} + \nu_{eo}$$

The electrophoretic mobility of the analyte and the electro-osmotic mobility may act in the same direction or in opposite directions, depending on the charge of the solute. In normal capillary electrophoresis, anions will migrate in the opposite direction to the electro-osmotic flow and their velocities will be smaller than the electro-osmotic velocity. Cations will migrate in the same direction as the electro-osmotic flow and their velocities will be greater than the electro-osmotic velocity. Under conditions in which there is a fast electro-osmotic velocity with respect to the electrophoretic velocity of the solutes, both cations and anions can be separated in the same run.

The time (*t*) taken by the solute to migrate the distance (*l*) from the injection end of the capillary to the detection point (capillary effective length) is given by the expression:

$$t = \frac{l}{\nu_{ep} + \nu_{eo}} = \frac{l \times L}{(\mu_{ep} + \mu_{eo}) \times V}$$

In general, uncoated fused-silica capillaries above pH 3 have negative charge due to ionised silanol groups in the inner wall. Consequently, the electro-osmotic flow is from anode to cathode. The electro-osmotic flow must remain constant from run to run if good reproducibility is to be obtained in the migration velocity of the solutes. For some applications, it may be necessary to reduce or suppress the electro-osmotic flow by modifying the inner wall of the capillary or by changing the concentration, composition and/or pH of the buffer solution.

After the introduction of the sample into the capillary, each analyte ion of the sample migrates within the background electrolyte as an independent zone, according to its electrophoretic mobility. Zone dispersion, that is the spreading of each solute band, results from different phenomena. Under ideal conditions the sole contribution to the solute-zone broadening is molecular diffusion of

the solute along the capillary (longitudinal diffusion). In this ideal case the efficiency of the zone, expressed as the number of theoretical plates (N), is given by:

$$N = \frac{(\mu_{ep} + \mu_{eo}) \times V \times l}{2 \times D \times L}$$

D = molecular diffusion coefficient of the solute in the buffer.

In practice, other phenomena such as heat dissipation, sample adsorption onto the capillary wall, mismatched conductivity between sample and buffer, length of the injection plug, detector cell size and unlevelled buffer reservoirs can also significantly contribute to band dispersion.

Separation between 2 bands (expressed as the resolution, R_s) can be obtained by modifying the electrophoretic mobility of the analytes, the electro-osmotic mobility induced in the capillary and by increasing the efficiency for the band of each analyte, according to the equation:

$$R_s = \frac{\sqrt{N}\,(\mu_{epb} - \mu_{epa})}{4\,(\overline{\mu}_{ep} + \mu_{eo})}$$

μ_{epa} and μ_{epb} = electrophoretic mobilities of the 2 analytes separated,

$\overline{\mu}_{ep}$ = mean electrophoretic mobility of the 2 analytes $\overline{\mu}_{ep} = \frac{1}{2}(\mu_{epb} + \mu_{epa})$.

APPARATUS

An apparatus for capillary electrophoresis is composed of:

- a high-voltage, controllable direct-current power supply;
- 2 buffer reservoirs, held at the same level, containing the prescribed anodic and cathodic solutions;
- 2 electrode assemblies (the cathode and the anode), immersed in the buffer reservoirs and connected to the power supply;
- a separation capillary (usually made of fused-silica) which, when used with some specific types of detectors, has an optical viewing window aligned with the detector. The ends of the capillary are placed in the buffer reservoirs. The capillary is filled with the solution prescribed in the monograph;
- a suitable injection system;
- a detector able to monitor the amount of substances of interest passing through a segment of the separation capillary at a given time; it is usually based on absorption spectrophotometry (UV and visible) or fluorimetry, but conductimetric, amperometric or mass spectrometric detection can be useful for specific applications; indirect detection is an alternative method used to detect non-UV-absorbing and non-fluorescent compounds;
- a thermostatic system able to maintain a constant temperature inside the capillary is recommended to obtain a good separation reproducibility;
- a recorder and a suitable integrator or a computer.

The definition of the injection process and its automation are critical for precise quantitative analysis. Modes of injection include gravity, pressure or vacuum injection and electrokinetic injection. The amount of each sample component introduced electrokinetically depends on its electrophoretic mobility, leading to possible discrimination using this injection mode.

Use the capillary, the buffer solutions, the preconditioning method, the sample solution and the migration conditions prescribed in the monograph of the considered substance.

The employed electrolytic solution is filtered to remove particles and degassed to avoid bubble formation that could interfere with the detection system or interrupt the electrical contact in the capillary during the separation run. A rigorous rinsing procedure should be developed for each analytical method to achieve reproducible migration times of the solutes.

CAPILLARY ZONE ELECTROPHORESIS

PRINCIPLE

In capillary zone electrophoresis, analytes are separated in a capillary containing only buffer without any anticonvective medium. With this technique, separation takes place because the different components of the sample migrate as discrete bands with different velocities. The velocity of each band depends on the electrophoretic mobility of the solute and the electro-osmotic flow in the capillary (see General Principles). Coated capillaries can be used to increase the separation capacity of those substances adsorbing on fused-silica surfaces.

Using this mode of capillary electrophoresis, the analysis of both small (M_r < 2000) and large molecules (2000 < M_r < 100 000) can be accomplished. Due to the high efficiency achieved in capillary zone electrophoresis, separation of molecules having only minute differences in their charge-to-mass ratio can be effected. This separation mode also allows the separation of chiral compounds by addition of chiral selectors to the separation buffer.

OPTIMISATION

Optimisation of the separation is a complex process where several separation parameters can play a major role. The main factors to be considered in the development of separations are instrumental and electrolytic solution parameters.

Instrumental parameters

Voltage. A Joule heating plot is useful in optimising the applied voltage and capillary temperature. Separation time is inversely proportional to applied voltage. However, an increase in the voltage used can cause excessive heat production, giving rise to temperature and, as a result thereof, viscosity gradients in the buffer inside the capillary. This effect causes band broadening and decreases resolution.

Polarity. Electrode polarity can be normal (anode at the inlet and cathode at the outlet) and the electro-osmotic flow will move toward the cathode. If the electrode polarity is reversed, the electro-osmotic flow is away from the outlet and only charged analytes with electrophoretic mobilities greater than the electro-osmotic flow will pass to the outlet.

Temperature. The main effect of temperature is observed on buffer viscosity and electrical conductivity, and therefore on migration velocity. In some cases, an increase in capillary temperature can cause a conformational change in proteins, modifying their migration time and the efficiency of the separation.

Capillary. The dimensions of the capillary (length and internal diameter) contribute to analysis time, efficiency of separations and load capacity. Increasing both effective length and total length can decrease the electric fields (working at constant voltage) which increases migration time. For a given buffer and electric field, heat dissipation, and hence sample band-broadening, depend on the internal diameter of the capillary. The latter also affects the detection limit, depending on the sample volume injected and the detection system employed.

Since the adsorption of the sample components on the capillary wall limits efficiency, methods to avoid these interactions should be considered in the development of a

separation method. In the specific case of proteins, several strategies have been devised to avoid adsorption on the capillary wall. Some of these strategies (use of extreme pH and adsorption of positively charged buffer additives) only require modification of the buffer composition to prevent protein adsorption. In other strategies, the internal wall of the capillary is coated with a polymer, covalently bonded to the silica, that prevents interaction between the proteins and the negatively charged silica surface. For this purpose, ready-to-use capillaries with coatings consisting of neutral-hydrophilic, cationic and anionic polymers are available.

Electrolytic solution parameters

Buffer type and concentration. Suitable buffers for capillary electrophoresis have an appropriate buffer capacity in the pH range of choice and low mobility to minimise current generation.

Matching buffer-ion mobility to solute mobility, whenever possible, is important for minimising band distortion. The type of sample solvent used is also important to achieve on-column sample focusing, which increases separation efficiency and improves detection.

An increase in buffer concentration (for a given pH) decreases electro-osmotic flow and solute velocity.

Buffer pH. The pH of the buffer can affect separation by modifying the charge of the analyte or additives, and by changing the electro-osmotic flow. In protein and peptide separation, changing the pH of the buffer from above to below the isoelectric point (pI) changes the net charge of the solute from negative to positive. An increase in the buffer pH generally increases the electro-osmotic flow.

Organic solvents. Organic modifiers (methanol, acetonitrile, etc.) may be added to the aqueous buffer to increase the solubility of the solute or other additives and/or to affect the degree of ionisation of the sample components. The addition of these organic modifiers to the buffer generally causes a decrease in the electro-osmotic flow.

Additives for chiral separations. For the separation of optical isomers, a chiral selector is added to the separation buffer. The most commonly used chiral selectors are cyclodextrins, but crown ethers, polysaccharides and proteins may also be used. Since chiral recognition is governed by the different interactions between the chiral selector and each of the enantiomers, the resolution achieved for the chiral compounds depends largely on the type of chiral selector used. In this regard, for the development of a given separation it may be useful to test cyclodextrins having a different cavity size (α-, β-, or γ-cyclodextrin) or modified cyclodextrins with neutral (methyl, ethyl, hydroxyalkyl, etc.) or ionisable (aminomethyl, carboxymethyl, sulphobutyl ether, etc.) groups. When using modified cyclodextrins, batch-to-batch variations in the degree of substitution of the cyclodextrins must be taken into account since it will influence the selectivity. Other factors controlling the resolution in chiral separations are concentration of chiral selector, composition and pH of the buffer and temperature. The use of organic additives, such as methanol or urea can also modify the resolution achieved.

CAPILLARY GEL ELECTROPHORESIS

PRINCIPLE

In capillary gel electrophoresis, separation takes place inside a capillary filled with a gel that acts as a molecular sieve. Molecules with similar charge-to-mass ratios are separated according to molecular size since smaller molecules move more freely through the network of the gel and therefore migrate faster than larger molecules. Different biological macromolecules (for example, proteins and DNA fragments), which often have similar charge-to-mass ratios, can thus be separated according to their molecular mass by capillary gel electrophoresis.

CHARACTERISTICS OF GELS

2 types of gels are used in capillary electrophoresis: permanently coated gels and dynamically coated gels. Permanently coated gels, such as cross-linked polyacrylamide, are prepared inside the capillary by polymerisation of the monomers. They are usually bonded to the fused-silica wall and cannot be removed without destroying the capillary. If the gels are used for protein analysis under reducing conditions, the separation buffer usually contains sodium dodecyl sulphate and the samples are denatured by heating in a mixture of sodium dodecyl sulphate and 2-mercaptoethanol or dithiothreitol before injection. When non-reducing conditions are used (for example, analysis of an intact antibody), 2-mercaptoethanol and dithiothreitol are not used. Separation in cross-linked gels can be optimised by modifying the separation buffer (as indicated in the capillary zone electrophoresis section) and controlling the gel porosity during the gel preparation. For cross-linked polyacrylamide gels, the porosity can be modified by changing the concentration of acrylamide and/or the proportion of cross-linker. As a rule, a decrease in the porosity of the gel leads to a decrease in the mobility of the solutes. Due to the rigidity of these gels, only electrokinetic injection can be used.

Dynamically coated gels are hydrophilic polymers, such as linear polyacrylamide, cellulose derivatives, dextran, etc., which can be dissolved in aqueous separation buffers giving rise to a separation medium that also acts as a molecular sieve. These separation media are easier to prepare than cross-linked polymers. They can be prepared in a vial and filled by pressure in a wall-coated capillary (with no electro-osmotic flow). Replacing the gel before every injection generally improves the separation reproducibility. The porosity of the gels can be increased by using polymers of higher molecular mass (at a given polymer concentration) or by decreasing the polymer concentration (for a given polymer molecular mass). A reduction in the gel porosity leads to a decrease in the mobility of the solute for the same buffer. Since the dissolution of these polymers in the buffer gives low viscosity solutions, both hydrodynamic and electrokinetic injection techniques can be used.

CAPILLARY ISOELECTRIC FOCUSING

PRINCIPLE

In isoelectric focusing, the molecules migrate under the influence of the electric field, so long as they are charged, in a pH gradient generated by ampholytes having pI values in a wide range (poly-aminocarboxylic acids), dissolved in the separation buffer.

The three basic steps of isoelectric focusing are loading, focusing and mobilisation.

Loading step. Two methods may be employed:

- loading in one step: the sample is mixed with ampholytes and introduced into the capillary either by pressure or vacuum;
- sequential loading: a leading buffer, then the ampholytes, then the sample mixed with ampholytes, again ampholytes alone and finally the terminating buffer are introduced into the capillary. The volume of the sample must be small enough not to modify the pH gradient.

Focusing step. When the voltage is applied, ampholytes migrate toward the cathode or the anode, according to their net charge, thus creating a pH gradient from anode (lower

pH) to cathode (higher pH). During this step the components to be separated migrate until they reach a pH corresponding to their isoelectric point (pI) and the current drops to very low values.

Mobilisation step. If mobilisation is required for detection, use one of the following methods.

- in the first method, mobilisation is accomplished during the focusing step under the effect of the electro-osmotic flow; the electro-osmotic flow must be small enough to allow the focusing of the components;
- in the second method, mobilisation is accomplished by applying positive pressure after the focusing step;
- in the third method, mobilisation is achieved after the focusing step by adding salts to the cathode reservoir or the anode reservoir (depending on the direction chosen for mobilisation) in order to alter the pH in the capillary when the voltage is applied. As the pH is changed, the proteins and ampholytes are mobilised in the direction of the reservoir which contains the added salts and pass the detector.

The separation achieved, expressed as ΔpI, depends on the pH gradient $(\mathrm{dpH}/\mathrm{d}x)$, the number of ampholytes having different pI values, the molecular diffusion coefficient (*D*), the intensity of the electric field (*E*) and the variation of the electrophoretic mobility of the analyte with the pH $(-\mathrm{d}\mu/\mathrm{dpH})$:

$$\Delta\mathrm{pI} = 3 \times \sqrt{\frac{D\,(\mathrm{dpH}/\mathrm{d}x)}{E\,(-\mathrm{d}\mu/\mathrm{dpH})}}$$

OPTIMISATION

The main parameters to be considered in the development of separations are:

Voltage. Capillary isoelectric focusing utilises very high electric fields, 300 V/cm to 1000 V/cm in the focusing step.

Capillary. The electro-osmotic flow must be reduced or suppressed depending on the mobilisation strategy (see above). Coated capillaries tend to reduce the electro-osmotic flow.

Solutions. The anode buffer reservoir is filled with a solution with a pH lower than the pI of the most acidic ampholyte and the cathode reservoir is filled with a solution with a pH higher than the pI of the most basic ampholyte. Phosphoric acid for the anode and sodium hydroxide for the cathode are frequently used.

Addition of a polymer, such as methylcellulose, in the ampholyte solution tends to suppress convective forces (if any) and electro-osmotic flow by increasing the viscosity. Commercial ampholytes are available covering many pH ranges and may be mixed if necessary to obtain an expanded pH range. Broad pH ranges are used to estimate the isoelectric point whereas narrower ranges are employed to improve accuracy. Calibration can be done by correlating migration time with isoelectric point for a series of protein markers.

During the focusing step precipitation of proteins at their isoelectric point can be prevented, if necessary, using buffer additives such as glycerol, surfactants, urea or zwitterionic buffers. However, depending on the concentration, urea denatures proteins.

MICELLAR ELECTROKINETIC CHROMATOGRAPHY (MEKC)

PRINCIPLE

In micellar electrokinetic chromatography, separation takes place in an electrolyte solution which contains a surfactant at a concentration above the critical micellar concentration (*cmc*). The solute molecules are distributed between the aqueous buffer and the pseudo-stationary phase composed of micelles, according to the partition coefficient of the solute. The technique can therefore be considered as a hybrid of electrophoresis and chromatography. It is a technique that can be used for the separation of both neutral and charged solutes, maintaining the efficiency, speed and instrumental suitability of capillary electrophoresis. One of the most widely used surfactants in MEKC is the anionic surfactant sodium dodecyl sulphate, although other surfactants, for example cationic surfactants such as cetyltrimethylammonium salts, are also used.

The separation mechanism is as follows. At neutral and alkaline pH, a strong electro-osmotic flow is generated and moves the separation buffer ions in the direction of the cathode. If sodium dodecyl sulphate is employed as the surfactant, the electrophoretic migration of the anionic micelle is in the opposite direction, towards the anode. As a result, the overall micelle migration velocity is slowed down compared to the bulk flow of the electrolytic solution. In the case of neutral solutes, since the analyte can partition between the micelle and the aqueous buffer, and has no electrophoretic mobility, the analyte migration velocity will depend only on the partition coefficient between the micelle and the aqueous buffer. In the electropherogram, the peaks corresponding to each uncharged solute are always between that of the electro-osmotic flow marker and that of the micelle (the time elapsed between these two peaks is called the separation window). For electrically charged solutes, the migration velocity depends on both the partition coefficient of the solute between the micelle and the aqueous buffer, and on the electrophoretic mobility of the solute in the absence of micelle.

Since the mechanism in MEKC of neutral and weakly ionised solutes is essentially chromatographic, migration of the solute and resolution can be rationalised in terms of the retention factor of the solute (*k*), also referred to as mass distribution ratio (D_m), which is the ratio of the number of moles of solute in the micelle to those in the mobile phase. For a neutral compound, *k* is given by:

$$k = \frac{t_R - t_0}{t_0 \times \left(1 - \frac{t_R}{t_{mc}}\right)} = K \times \frac{V_S}{V_M}$$

t_R = migration time of the solute,

t_0 = analysis time of an unretained solute (determined by injecting an electro-osmotic flow marker which does not enter the micelle, for instance methanol),

t_{mc} = micelle migration time (measured by injecting a micelle marker, such as Sudan III, which migrates while continuously associated in the micelle),

K = partition coefficient of the solute,

V_S = volume of the micellar phase,

V_M = volume of the mobile phase.

Likewise, the resolution between 2 closely-migrating solutes (R_s) is given by:

$$R_s = \frac{\sqrt{N}}{4} \times \frac{\alpha - 1}{\alpha} \times \frac{k_b}{k_b + 1} \times \frac{1 - \left(\frac{t_0}{t_{mc}}\right)}{1 + k_a \times \left(\frac{t_0}{t_{mc}}\right)}$$

N = number of theoretical plates for one of the solutes,

α = selectivity,

k_a and k_b = retention factors for both solutes, respectively ($k_b > k_a$).

Similar, but not identical, equations give k and R_s values for electrically charged solutes.

OPTIMISATION

The main parameters to be considered in the development of separations by MEKC are instrumental and electrolytic solution parameters.

Instrumental parameters

Voltage. Separation time is inversely proportional to applied voltage. However, an increase in voltage can cause excessive heat production that gives rise to temperature gradients and viscosity gradients of the buffer in the cross-section of the capillary. This effect can be significant with high conductivity buffers such as those containing micelles. Poor heat dissipation causes band broadening and decreases resolution.

Temperature. Variations in capillary temperature affect the partition coefficient of the solute between the buffer and the micelles, the critical micellar concentration and the viscosity of the buffer. These parameters contribute to the migration time of the solutes. The use of a good cooling system improves the reproducibility of the migration time for the solutes.

Capillary. As in capillary zone electrophoresis, the dimensions of the capillary (length and internal diameter) contribute to analysis time and efficiency of separations. Increasing both effective length and total length can decrease the electric fields (working at constant voltage), increase migration time and improve the separation efficiency. The internal diameter controls heat dissipation (for a given buffer and electric field) and consequently the sample band broadening.

Electrolytic solution parameters

Surfactant type and concentration. The type of surfactant, in the same way as the stationary phase in chromatography, affects the resolution since it modifies separation selectivity. Also, the log k of a neutral compound increases linearly with the concentration of surfactant in the mobile phase. Since resolution in MEKC reaches a maximum when k approaches the value of $\sqrt{t_{mc}/t_0}$, modifying the concentration of surfactant in the mobile phase changes the resolution obtained.

Buffer pH. Although pH does not modify the partition coefficient of non-ionised solutes, it can modify the electro-osmotic flow in uncoated capillaries. A decrease in the buffer pH decreases the electro-osmotic flow and therefore increases the resolution of the neutral solutes in MEKC, resulting in a longer analysis time.

Organic solvents. To improve MEKC separation of hydrophobic compounds, organic modifiers (methanol, propanol, acetonitrile, etc.) can be added to the electrolytic solution. The addition of these modifiers usually decreases migration time and the selectivity of the separation. Since the addition of organic modifiers affects the critical micellar concentration, a given surfactant concentration can be used only within a certain percentage of organic modifier before the micellisation is inhibited or adversely affected, resulting in the absence of micelles and, therefore, in the absence of partition. The dissociation of micelles in the presence of a high content of organic solvent does not always mean that the separation will no longer be possible; in some cases the hydrophobic interaction between the ionic surfactant monomer and the neutral solutes forms solvophobic complexes that can be separated electrophoretically.

Additives for chiral separations. For the separation of enantiomers using MEKC, a chiral selector is included in the micellar system, either covalently bound to the surfactant or added to the micellar separation electrolyte. Micelles that have a moiety with chiral discrimination properties include salts of *N*-dodecanoyl-L-amino acids, bile salts, etc. Chiral resolution can also be achieved using chiral discriminators, such as cyclodextrins, added to the electrolytic solutions which contain micellised achiral surfactants.

Other additives. Several strategies can be carried out to modify selectivity, by adding chemicals to the buffer. The addition of several types of cyclodextrins to the buffer can also be used to reduce the interaction of hydrophobic solutes with the micelle, thus increasing the selectivity for this type of compound.

The addition of substances able to modify solute-micelle interactions by adsorption on the latter, is used to improve the selectivity of the separations in MEKC. These additives may be a second surfactant (ionic or non-ionic) which gives rise to mixed micelles or metallic cations which dissolve in the micelle and form co-ordination complexes with the solutes.

QUANTIFICATION

Peak areas must be divided by the corresponding migration time to give the corrected area in order to:

- compensate for the shift in migration time from run to run, thus reducing the variation of the response,
- compensate for the different responses of sample constituents with different migration times.

Where an internal standard is used, verify that no peak of the substance to be examined is masked by that of the internal standard.

CALCULATIONS

From the values obtained, calculate the content of the component or components being examined. When prescribed, the percentage content of one or more components of the sample to be examined is calculated by determining the corrected area(s) of the peak(s) as a percentage of the total of the corrected areas of all peaks, excluding those due to solvents or any added reagents (normalisation procedure). The use of an automatic integration system (integrator or data acquisition and processing system) is recommended.

SYSTEM SUITABILITY

In order to check the behaviour of the capillary electrophoresis system, system suitability parameters are used. The choice of these parameters depends on the mode of capillary electrophoresis used. They are: retention factor (k) (only for micellar electrokinetic chromatography), apparent number of theoretical plates (N), symmetry factor (A_s) and resolution (R_s). In previous sections, the theoretical expressions for N and R_s have been described, but more practical equations that allow these parameters to be calculated from the electropherograms are given below.

APPARENT NUMBER OF THEORETICAL PLATES

The apparent number of theoretical plates (N) may be calculated using the expression:

$$N = 5.54 \times \left(\frac{t_R}{w_h}\right)^2$$

t_R = migration time or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,

w_h = width of the peak at half-height.

RESOLUTION

The resolution (R_s) between peaks of similar height of 2 components may be calculated using the expression:

$$R_s = \frac{1.18 \times (t_{R2} - t_{R1})}{w_{h1} + w_{h2}}$$

$$t_{R2} > t_{R1}$$

t_{R1} and t_{R2} = migration times or distances along the baseline from the point of injection to the perpendiculars dropped from the maxima of two adjacent peaks,

w_{h1} and w_{h2} = peak widths at half-height.

When appropriate, the resolution may be calculated by measuring the height of the valley (H_v) between 2 partly resolved peaks in a standard preparation and the height of the smaller peak (H_p) and calculating the peak-to-valley ratio:

$$\frac{p}{v} = \frac{H_p}{H_v}$$

SYMMETRY FACTOR

The symmetry factor (A_s) of a peak may be calculated using the expression:

$$A_s = \frac{w_{0.05}}{2d}$$

$w_{0.05}$ = width of the peak at one-twentieth of the peak height,

d = distance between the perpendicular dropped from the peak maximum and the leading edge of the peak at one-twentieth of the peak height.

Tests for area repeatability (standard deviation of areas or of the area/migration-time ratio) and for migration time repeatability (standard deviation of migration time) are introduced as suitability parameters. Migration time repeatability provides a test for the suitability of the capillary washing procedures. An alternative practice to avoid the lack of repeatability of the migration time is to use migration time relative to an internal standard.

A test for the verification of the signal-to-noise ratio for a standard preparation (or the determination of the limit of quantification) may also be useful for the determination of related substances.

SIGNAL-TO-NOISE RATIO

The detection limit and quantification limit correspond to signal-to-noise ratios of 3 and 10 respectively. The signal-to-noise ratio (S/N) is calculated using the expression:

$$\frac{S}{N} = \frac{2H}{h}$$

H = height of the peak corresponding to the component concerned, in the electropherogram obtained with the prescribed reference solution, measured from the maximum of the peak to the extrapolated baseline of the signal observed over a distance equal to twenty times the width at half-height,

h = range of the background in an electropherogram obtained after injection of a blank, observed over a distance equal to twenty times the width at the half-height of the peak in the electropherogram obtained with the prescribed reference solution and, if possible, situated equally around the place where this peak would be found.

01/2008:20248

2.2.48. RAMAN SPECTROMETRY

Raman spectrometry (inelastic light scattering) is a light-scattering process in which the specimen under examination is irradiated with intense monochromatic light (usually laser light) and the light scattered from the specimen is analysed for frequency shifts.

Raman spectrometry is complementary to infrared spectrometry in the sense that the two techniques both probe the molecular vibrations in a material. However, Raman and infrared spectrometry have different relative sensitivities for different functional groups. Raman spectrometry is particularly sensitive to non-polar bonds (e.g. C-C single or multiple bonds) and less sensitive to polar bonds. Hence, water, which has a strong infrared absorption spectrum, is a weak Raman scatterer and is thus well suited as a solvent for Raman spectrometry.

Apparatus: Spectrometers for recording Raman spectra typically consist of the following components:

- a monochromatic light source, typically a laser, with a wavelength in the ultraviolet, visible or near-infrared region,
- suitable optics (lens, mirrors or optical-fibre assembly) which directs the irradiating light to and collects the scattered light from the sample,
- an optical device (monochromator or filter) that transmits the frequency-shifted Raman scattering and prevents the intense incident frequency (Rayleigh scattering) from reaching the detector,
- a dispersing device (grating or prism monochromator) combined with wavelength-selecting slits and a detector (usually a photomultiplier tube),

  or:

- a dispersing device (grating or prism) combined with a multichannel detector (usually a charge-coupled device (CCD)),

  or:

- an interferometer with a detector that records the intensity of the scattered light over time, and a data-handling device that converts the data to the frequency or wavenumber domain by a Fourier-transform calculation.

PREPARATION OF THE SAMPLE

Raman spectra can be obtained from solids, liquids and gases either directly, or in glass containers or tubes, generally without prior sample preparation or dilution.

A major limitation of Raman spectrometry is that impurities may cause fluorescence that interferes with the detection of the much weaker Raman signal. Fluorescence may be avoided by choosing a laser source with a longer wavelength, for example in the near infrared, as the exciting line. The intensity of certain Raman lines may be enhanced in a number of ways, for instance in Resonance Raman (RR) and by Surface Enhanced Raman Spectrometry (SERS).

Due to the narrow focus of the irradiating laser beam, the spectrum is typically obtained from only a few microlitres of sample. Hence, sample inhomogeneities must be considered, unless the sample volume is increased, for example by rotation of the sample.

IDENTIFICATION AND QUANTITATION USING REFERENCE SUBSTANCES

Prepare the substance to be examined and the reference substance by the same procedure and record the spectra under the same operational conditions. The maxima in the spectrum obtained with the substance to be examined correspond in position and relative intensity to those in the spectrum obtained with the reference substance (CRS).

When the spectra recorded in the solid state show differences in the positions of the maxima, treat the substance to be examined and the reference substance in the same manner so that they crystallise or are produced in the same form, or proceed as described in the monograph, then record the spectra.

While Beer-Lambert's law is not valid for Raman spectrometry, Raman intensity is directly proportional to the concentration of the scattering species. As for other spectroscopic techniques, quantitation can be performed using known amounts or concentrations of reference substances. Owing to the small spatial resolution of the technique, care must be taken to ensure representative samples of standards and unknowns, for example by making sure that they are in the same physical state or by using an internal standard for liquid samples.

IDENTIFICATION AND QUANTITATION USING SPECTRAL LIBRARIES AND STATISTICAL METHODS FOR CLASSIFICATION AND CALIBRATION

Control of instrument performance. Use the apparatus according to the manufacturer's instructions and carry out the prescribed calibrations and system performance tests at regular intervals, depending on the use of the apparatus and the substances to be examined. When using Raman spectrometry for quantitative determinations, or when setting up spectral reference libraries for (chemometric) classification or calibration, particular care should be taken to ensure that corrections are made or measures are taken to control the variability in wavenumber and response-intensity of the instrumentation.

Verification of the wavenumber scale. Verify the wavenumber scale of the Raman shift (normally expressed in reciprocal centimetres) using a suitable standard which has characteristic maxima at the wavenumbers under investigation, for example, an organic substance, an Ne lamp or Ar^+ plasma lines from an argon-ion laser.

The calibration measurement should be matched to the sample type, i.e. a solid calibration sample should be used for solid samples and a liquid calibration sample for liquid samples. Choose a suitable substance (e.g. indene, cyclohexane or naphthalene) for which accurate wavenumber shifts have been established. The indene sample can favourably be placed in an NMR tube, evacuated and sealed under inert gas, and stored cool in the dark to avoid degradation of the sample.

Table 2.2.48.-1. – *Wavenumber shifts (and acceptable tolerances) of cyclohexane, indene and naphthalene.*

cyclohexane [A]	indene [B]	naphthalene [A]
		3056.4 (± 1.5)
2938.3 (± 1.5)		
2923.8 (± 1.5)		
2852.9 (± 1.5)		
	1609.7 (± 1.0)	1576.6 (± 1.0)
1444.4 (± 1.0)	1552.6 (± 1.0)	1464.5 (± 1.0)

[A] *Standard guide for Raman shift standards for spectrometer calibration* (American Society for Testing and Materials ASTM E 1840).

[B] D. A. Carter, W. R. Thompson, C. E. Taylor and J. E. Pemberton, *Applied Spectroscopy,* 1995, 49 (11), 1561-1576.

Verification of the response-intensity scale. The absolute and relative intensities of the Raman bands are affected by several factors including:

- the state of polarisation of the irradiating light,
- the state of polarisation of the collection optics,
- the intensity of the irradiating light,
- differences in instrument response,
- differences in focus and geometry at sample,
- differences in packing density for solid samples.

Appropriate acceptance criteria will vary with the application but a day-to-day variation of ± 10 per cent in relative band intensities is achievable in most cases.

Establishment of a spectral reference library. Record the spectra of a suitable number of materials which have been fully tested (e.g. as prescribed in a monograph) and which exhibit the variation (manufacturer, batch, crystal modification, particle size, etc.) typical of the material to be analysed. The set of spectra represents the information that defines the similarity border or quantitative limits, which may be used, e.g. to identify the substance or control the amount formed in a manufacturing process. The number of substances in the database depends on the specific application. The collection of spectra in the database may be represented in different ways defined by the mathematical technique used for classification or quantitation.

The selectivity of the database which makes it possible to identify positively a given material and distinguish it adequately from other materials in the database is to be established during the validation procedure. This selectivity must be challenged on a regular basis to ensure ongoing validity of the database; this is especially necessary after any major change in a substance (e.g. change in supplier or in the manufacturing process of the material) or in the set-up of the Raman instrument (e.g. verification of the wavenumber and response repeatability of the spectrometer).

This database is then valid for use only with the originating instrument, or with a similar instrument, provided the transferred database has been demonstrated to remain valid.

Method. Prepare and examine the sample in the same manner as for the establishment of the database. A suitable mathematical transformation of the Raman spectrum may be calculated to facilitate spectrum comparison or quantitative prediction.

Comparison of the spectra or transforms of the spectra or quantitative prediction of properties or amounts in the material in question may involve the use of a suitable chemometric or statistical classification or calibration technique.

2.2.49. FALLING BALL VISCOMETER METHOD

The determination of dynamic viscosity of Newtonian liquids using a suitable falling ball viscometer is performed at 20 ± 0.1 °C, unless otherwise prescribed in the monograph. The time required for a test ball to fall in the liquid to be examined from one ring mark to the other is determined. If no stricter limit is defined for the equipment used the result is valid only if 2 consecutive measures do not differ by more than 1.5 per cent.

Apparatus. The falling ball viscometer consists of: a glass tube enclosed in a mantle, which allow precise control of temperature; six balls made of glass, nickel-iron or steel with different densities and diameters. The tube is fixed in such a way that the axis is inclined by 10 ± 1° with regard to the vertical. The tube has 2 ring marks which define the distance the ball has to roll. Commercially available apparatus is supplied with tables giving the constants, the density of the balls and the suitability of the different balls for the expected range of viscosity.

Method. Fill the clean, dry tube of the viscometer, previously brought to 20 ± 0.1 °C, with the liquid to be examined, avoiding bubbles. Add the ball suitable for the range of viscosity of the liquid so as to obtain a falling time not less than 30 s. Close the tube and maintain the solution at 20 ± 0.1 °C for at least 15 min. Let the ball run through the liquid between the 2 ring marks once without measurement. Let it run again and measure with a stop-watch, to the nearest one-fifth of a second, the time required for the ball to roll from the upper to the lower ring mark. Repeat the test run at least 3 times.

Calculate the dynamic viscosity η in millipascal seconds using the formula:

$$\eta = k\,(\rho_1 - \rho_2) \times t$$

- k = constant, expressed in millimeter squared per second squared,
- ρ_1 = density of the ball used, expressed in grams per cubic centimetre,
- ρ_2 = density of the liquid to be examined, expressed in grams per cubic centimetre, obtained by multiplying its relative density d_{20}^{20} by 0.9982,
- t = falling time of the ball, in seconds.

2.2.54. ISOELECTRIC FOCUSING

GENERAL PRINCIPLES

Isoelectric focusing (IEF) is a method of electrophoresis that separates proteins according to their isoelectric point. Separation is carried out in a slab of polyacrylamide or agarose gel that contains a mixture of amphoteric electrolytes (ampholytes). When subjected to an electric field, the ampholytes migrate in the gel to create a pH gradient. In some cases gels containing an immobilised pH gradient, prepared by incorporating weak acids and bases to specific regions of the gel network during the preparation of the gel, are used. When the applied proteins reach the gel fraction that has a pH that is the same as their isoelectric point (pI), their charge is neutralised and migration ceases. Gradients can be made over various ranges of pH, according to the mixture of ampholytes chosen.

THEORETICAL ASPECTS

When a protein is at the position of its isoelectric point, it has no net charge and cannot be moved in a gel matrix by the electric field. It may, however, move from that position by diffusion. The pH gradient forces a protein to remain in its isoelectric point position, thus concentrating it; this concentrating effect is called "focusing". Increasing the applied voltage or reducing the sample load result in improved separation of bands. The applied voltage is limited by the heat generated, which must be dissipated. The use of thin gels and an efficient cooling plate controlled by a thermostatic circulator prevents the burning of the gel whilst allowing sharp focusing. The separation is estimated by determining the minimum pI difference (ΔpI), which is necessary to separate 2 neighbouring bands:

$$\Delta\mathrm{pI} = 3 \times \sqrt{\frac{D\,(\mathrm{dpH}/\mathrm{d}x)}{E\,(-\mathrm{d}\mu/\mathrm{dpH})}}$$

- D = diffusion coefficient of the protein,
- $\frac{\mathrm{dpH}}{\mathrm{d}x}$ = pH gradient,
- E = intensity of the electric field, in volts per centimetre,
- $-\frac{\mathrm{d}\mu}{\mathrm{dpH}}$ = variation of the solute mobility with the pH in the region close to the pI.

Since D and $-\frac{\mathrm{d}\mu}{\mathrm{dpH}}$ for a given protein cannot be altered, the separation can be improved by using a narrower pH range and by increasing the intensity of the electric field.

Resolution between protein bands on an IEF gel prepared with carrier ampholytes can be quite good. Improvements in resolution may be achieved by using immobilised pH gradients where the buffering species, which are analogous to carrier ampholytes, are copolymerised within the gel matrix. Proteins exhibiting pIs differing by as little as 0.02 pH units may be resolved using a gel prepared with carrier ampholytes while immobilised pH gradients can resolve proteins differing by approximately 0.001 pH units.

PRACTICAL ASPECTS

Special attention must be paid to sample characteristics and/or preparation. Having salt in the sample can be problematic and it is best to prepare the sample, if possible, in deionised water or 2 per cent ampholytes, using dialysis or gel filtration if necessary.

The time required for completion of focusing in thin-layer polyacrylamide gels is determined by placing a coloured protein (e.g. haemoglobin) at different positions on the gel surface and by applying the electric field: the steady state is reached when all applications give an identical band pattern. In some protocols the completion of the focusing is indicated by the time elapsed after the sample application.

The IEF gel can be used as an identity test when the migration pattern on the gel is compared to a suitable standard preparation and IEF calibration proteins, the IEF gel can be used as a limit test when the density of a band on IEF is compared subjectively with the density of bands appearing in a standard preparation, or it can be used as a quantitative test when the density is measured using a densitometer or similar instrumentation to determine the relative concentration of protein in the bands subject to validation.

APPARATUS

An apparatus for IEF consists of:

- a controllable generator for constant potential, current and power; potentials of 2500 V have been used and are considered optimal under a given set of operating conditions; a supply of up to 30 W of constant power is recommended;
- a rigid plastic IEF chamber that contains a cooled plate, of suitable material, to support the gel;
- a plastic cover with platinum electrodes that are connected to the gel by means of paper wicks of suitable width, length and thickness, impregnated with solutions of anodic and cathodic electrolytes.

ISOELECTRIC FOCUSING IN POLYACRYLAMIDE GELS: DETAILED PROCEDURE

The following method is a detailed description of an IEF procedure in thick polyacrylamide slab gels, which is used unless otherwise stated in the monograph.

PREPARATION OF THE GELS

Mould. The mould (see Figure 2.2.54.-1) is composed of a glass plate (A) on which a polyester film (B) is placed to facilitate handling of the gel, one or more spacers (C), a second glass plate (D) and clamps to hold the structure together.

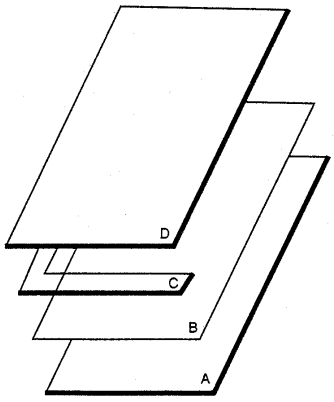

Figure 2.2.54.-1 – *Mould*

7.5 per cent polyacrylamide gel. Dissolve 29.1 g of *acrylamide R* and 0.9 g of *methylenebisacrylamide R* in 100 ml of *water R*. To 2.5 volumes of this solution, add the mixture of ampholytes specified in the monograph and dilute to 10 volumes with *water R*. Mix carefully and degas the solution.

Preparation of the mould. Place the polyester film on the lower glass plate, apply the spacer, place the second glass plate and fit the clamps. Before use, place the solution on a magnetic stirrer and add 0.25 volumes of a 100 g/l solution of *ammonium persulphate R* and 0.25 volumes of *tetramethylethylenediamine R*. Immediately fill the space between the glass plates of the mould with the solution.

METHOD

Dismantle the mould and, making use of the polyester film, transfer the gel onto the cooled support, wetted with a few millilitres of a suitable liquid, taking care to avoid forming air bubbles. Prepare the test solutions and reference solutions as specified in the monograph. Place strips of paper for sample application, about 10 mm × 5 mm in size, on the gel and impregnate each with the prescribed amount of the test and reference solutions. Also apply the prescribed quantity of a solution of proteins with known isoelectric points as pH markers to calibrate the gel. In some protocols the gel has pre-cast slots where a solution of the sample is applied instead of using impregnated paper strips. Cut 2 strips of paper to the length of the gel and impregnate them with the electrolyte solutions: acid for the anode and alkaline for the cathode. The compositions of the anode and cathode solutions are given in the monograph. Apply these paper wicks to each side of the gel several millimetres from the edge. Fit the cover so that the electrodes are in contact with the wicks (respecting the anodic and cathodic poles). Proceed with the isoelectric focusing by applying the electrical parameters described in the monograph. Switch off the current when the migration of the mixture of standard proteins has stabilised. Using forceps, remove the sample application strips and the 2 electrode wicks. Immerse the gel in *fixing solution for isoelectric focusing in polyacrylamide gel R*. Incubate with gentle shaking at room temperature for 30 min. Drain off the solution and add 200 ml of *destaining solution R*. Incubate with shaking for 1 h. Drain the gel, add *coomassie staining solution R*. Incubate for 30 min. Destain the gel by passive diffusion with *destaining solution R* until the bands are well visualised against a clear background. Locate the position and intensity of the bands in the electropherogram as prescribed in the monograph.

VARIATIONS TO THE DETAILED PROCEDURE (SUBJECT TO VALIDATION)

Where reference to the general method on isoelectric focusing is made, variations in methodology or procedure may be made subject to validation. These include:

- the use of commercially available pre-cast gels and of commercial staining and destaining kits,
- the use of immobilised pH gradients,
- the use of rod gels,
- the use of gel cassettes of different dimensions, including ultra-thin (0.2 mm) gels,
- variations in the sample application procedure, including different sample volumes or the use of sample application masks or wicks other than paper,
- the use of alternate running conditions, including variations in the electric field depending on gel dimensions and equipment, and the use of fixed migration times rather than subjective interpretation of band stability,
- the inclusion of a pre-focusing step,
- the use of automated instrumentation,
- the use of agarose gels.

VALIDATION OF ISO-ELECTRIC FOCUSING PROCEDURES

Where alternative methods to the detailed procedure are employed they must be validated. The following criteria may be used to validate the separation:

- formation of a stable pH gradient of desired characteristics, assessed for example using coloured pH markers of known isoelectric points,

– comparison with the electropherogram provided with the chemical reference substance for the preparation to be examined,
– any other validation criteria as prescribed in the monograph.

SPECIFIED VARIATIONS TO THE GENERAL METHOD

Variations to the general method required for the analysis of specific substances may be specified in detail in monographs. These include:

– the addition of urea in the gel (3 M concentration is often satisfactory to keep protein in solution but up to 8 M can be used): some proteins precipitate at their isoelectric point; in this case, urea is included in the gel formulation to keep the protein in solution; if urea is used, only fresh solutions should be used to prevent carbamylation of the protein;
– the use of alternative staining methods;
– the use of gel additives such as non-ionic detergents (e.g. octylglucoside) or zwitterionic detergents (e.g., CHAPS or CHAPSO), and the addition of ampholyte to the sample, to prevent proteins from aggregating or precipitating.

POINTS TO CONSIDER

Samples can be applied to any area on the gel, but to protect the proteins from extreme pH environments samples should not be applied close to either electrode. During method development the analyst can try applying the protein in 3 positions on the gel (i.e. middle and both ends); the pattern of a protein applied at opposite ends of the gel may not be identical.

A phenomenon known as cathodic drift, where the pH gradient decays over time, may occur if a gel is focused too long. Although not well understood, electroendoosmosis and absorption of carbon dioxide may be factors that lead to cathodic drift. Cathodic drift is observed as focused protein migrating off the cathode end of the gel. Immobilised pH gradients may be used to address this problem.

Efficient cooling (approximately 4 °C) of the bed that the gel lies on during focusing is important. High field strengths used during isoelectric focusing can lead to overheating and affect the quality of the focused gel.

01/2008:20255

2.2.55. PEPTIDE MAPPING

Peptide mapping is an identity test for proteins, especially those obtained by rDNA technology. It involves the chemical or enzymatic treatment of a protein resulting in the formation of peptide fragments followed by separation and identification of these fragments in a reproducible manner. It is a powerful test that is capable of identifying almost any single amino acid changes resulting from events such as errors in the reading of complementary DNA (cDNA) sequences or point mutations. Peptide mapping is a comparative procedure because the information obtained, compared to a reference substance similarly treated, confirms the primary structure of the protein, is capable of detecting whether alterations in structure have occurred, and demonstrates process consistency and genetic stability. Each protein presents unique characteristics which must be well understood so that the scientific and analytical approaches permit validated development of a peptide map that provides sufficient specificity.

This chapter provides detailed assistance in the application of peptide mapping and its validation to characterise the desired protein, to evaluate the stability of the expression construct of cells used for recombinant DNA products and to evaluate the consistency of the overall process, to assess product stability as well as to ensure the identity of the protein, or to detect the presence of protein variant.

Peptide mapping is not a general method, but involves developing specific maps for each unique protein. Although the technology is evolving rapidly, there are certain methods that are generally accepted. Variations of these methods will be indicated, when appropriate, in specific monographs.

A peptide map may be viewed as a fingerprint of a protein and is the end product of several chemical processes that provide a comprehensive understanding of the protein being analysed. 4 principal steps are necessary for the development of the procedure: isolation and purification of the protein, if the protein is part of a formulation; selective cleavage of the peptide bonds; chromatographic separation of the peptides; and analysis and identification of the peptides. A test sample is digested and assayed in parallel with a reference substance. Complete cleavage of peptide bonds is more likely to occur when enzymes such as endoproteases (e.g., trypsin) are used, instead of chemical cleavage reagents. A map must contain enough peptides to be meaningful. On the other hand, if there are too many fragments, the map might lose its specificity because many proteins will then have the same profiles.

ISOLATION AND PURIFICATION

Isolation and purification are necessary for analysis of bulk drugs or dosage forms containing interfering excipients and carrier proteins and, when required, will be specified in the monograph. Quantitative recovery of protein from the dosage form must be validated.

SELECTIVE CLEAVAGE OF PEPTIDE BONDS

The selection of the approach used for the cleavage of peptide bonds will depend on the protein under test. This selection process involves determination of the type of cleavage to be employed, enzymatic or chemical, and the type of cleavage agent within the chosen category. Several cleavage agents and their specificity are shown in Table 2.2.55.-1. This list is not all-inclusive and will be expanded as other cleavage agents are identified.

Pretreatment of sample. Depending on the size or the configuration of the protein, different approaches in the pretreatment of samples can be used. If trypsin is used as a cleavage agent for proteins with a molecular mass greater than 100 000 Da, lysine residues must be protected by citraconylation or maleylation; otherwise, too many peptides will be generated.

Pretreatment of the cleavage agent. Pretreatment of cleavage agents, especially enzymatic agents, might be necessary for purification purposes to ensure reproducibility of the map. For example, trypsin used as a cleavage agent will have to be treated with tosyl-L-phenylalanine chloromethyl ketone to inactivate chymotrypsin. Other methods, such as purification of trypsin by high performance liquid chromatography (HPLC) or immobilisation of enzyme on a gel support, have been successfully used when only a small amount of protein is available.

Pretreatment of the protein. Under certain conditions, it might be necessary to concentrate the sample or to separate the protein from added substances and stabilisers used in formulation of the product, if these interfere with the mapping procedure. Physical procedures used

Table 2.2.55.-1. – *Examples of cleavage agents*

Type	Agent	Specificity
Enzymatic	Trypsin (EC 3.4.21.4)	*C*-terminal side of Arg and Lys
	Chymotrypsin (EC 3.4.21.1)	*C*-terminal side of hydrophobic residues (e.g. Leu, Met, Ala, aromatics)
	Pepsin (EC 3.4.23.1 and 2)	Non-specific digest
	Lysyl endopeptidase (Lys-C endopeptidase) (EC 3.4.21.50)	*C*-terminal side of Lys
	Glutamyl endopeptidase (from *S. aureus* strain V8) (EC 3.4.21.19)	*C*-terminal side of Glu and Asp
	Peptidyl-Asp metallo-endopeptidase (endoproteinase Asp-N)	*N*-terminal side of Asp
	Clostripain (EC 3.4.22.8)	*C*-terminal side of Arg
Chemical	Cyanogen bromide	*C*-terminal side of Met
	2-Nitro-5-thio-cyanobenzoic acid	*N*-terminal side of Cys
	O-Iodosobenzoic acid	*C*-terminal side of Trp and Tyr
	Dilute acid	Asp and Pro
	BNPS-skatole	Trp

for pretreatment can include ultrafiltration, column chromatography and lyophilization. Other pretreatments, such as the addition of chaotropic agents (e.g. urea) can be used to unfold the protein prior to mapping. To allow the enzyme to have full access to cleavage sites and permit some unfolding of the protein, it is often necessary to reduce and alkylate the disulphide bonds prior to digestion.

Digestion with trypsin can introduce ambiguities in the peptide map due to side reactions occurring during the digestion reaction, such as non-specific cleavage, deamidation, disulphide isomerisation, oxidation of methionine residues, or formation of pyroglutamic groups created from the deamidation of glutamine at the *N*-terminal side of a peptide. Furthermore, peaks may be produced by autohydrolysis of trypsin. Their intensities depend on the ratio of trypsin to protein. To avoid autohydrolysis, solutions of proteases may be prepared at a pH that is not optimal (e.g. at pH 5 for trypsin), which would mean that the enzyme would not become active until diluted with the digest buffer.

Establishment of optimal digestion conditions. Factors that affect the completeness and effectiveness of digestion of proteins are those that could affect any chemical or enzymatic reactions.

pH of the reaction milieu. The pH of the digestion mixture is empirically determined to ensure the optimisation of the performance of the given cleavage agent. For example, when using cyanogen bromide as a cleavage agent, a highly acidic environment (e.g. pH 2, formic acid) is necessary; however, when using trypsin as a cleavage agent, a slightly alkaline environment (pH 8) is optimal. As a general rule, the pH of the reaction milieu must not alter the chemical integrity of the protein during the digestion and must not change during the course of the fragmentation reaction.

Temperature. A temperature between 25 °C and 37 °C is adequate for most digestions. The temperature used is intended to minimise chemical side reactions. The type of protein under test will dictate the temperature of the reaction milieu, because some proteins are more susceptible to denaturation as the temperature of the reaction increases. For example, digestion of recombinant bovine somatropin is conducted at 4 °C, because at higher temperatures it will precipitate during digestion.

Time. If sufficient sample is available, a time course study is considered in order to determine the optimum time to obtain a reproducible map and avoid incomplete digestion. Time of digestion varies from 2 h to 30 h. The reaction is stopped by the addition of an acid which does not interfere in the map or by freezing.

Amount of cleavage agent used. Although excessive amounts of cleavage agent are used to accomplish a reasonably rapid digestion time (i.e. 6-20 hours), the amount of cleavage agent is minimised to avoid its contribution to the chromatographic map pattern. A protein to protease ratio between 20:1 and 200:1 is generally used. It is recommended that the cleavage agent is added in 2 or more stages to optimise cleavage. Nonetheless, the final reaction volume remains small enough to facilitate the next step in peptide mapping, the separation step. To sort out digestion artifacts that might interfere with the subsequent analysis, a blank determination is performed, using a digestion control with all the reagents, except the test protein.

CHROMATOGRAPHIC SEPARATION

Many techniques are used to separate peptides for mapping. The selection of a technique depends on the protein being mapped. Techniques that have been successfully used for separation of peptides are shown in Table 2.2.55-2. In this section, a most widely used reversed-phase HPLC method is described as one of the procedures of chromatographic separation.

The purity of solvents and mobile phases is a critical factor in HPLC separation. HPLC-grade solvents and water that are commercially available, are recommended for reversed-phase HPLC. Dissolved gases present a problem in gradient systems where the solubility of the gas in a solvent may be less in a mixture than in a single solvent. Vacuum degassing and agitation by sonication are often used as useful degassing procedures. When solid particles in the solvents are drawn into the HPLC system, they can damage the sealing of pump valves or clog the top of the chromatographic column. Both pre- and post-pump filtration is also recommended.

Table 2.2.55-2. – *Techniques used for the separation of peptides*

Reversed-phase high performance liquid chromatography (HPLC)
Ion-exchange chromatography (IEC)
Hydrophobic interaction chromatography (HIC)
Polyacrylamide gel electrophoresis (PAGE), non-denaturating
Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE)
Capillary electrophoresis (CE)
Paper chromatography-high voltage (PCHV)
High voltage-paper electrophoresis (HVPE)

Chromatographic column. The selection of a chromatographic column is empirically determined for each protein. Columns with 10 nm or 30 nm pore size with silica support can give optimal separation. For smaller peptides, *octylsilyl silica gel for chromatography R* (3-10 µm) and *octadecylsilyl silica gel for chromatography R* (3-10 µm) column packings are more efficient than *butylsilyl silica gel for chromatography R* (5-10 µm).

Solvent. The most commonly used solvent is water with acetonitrile as the organic modifier to which not more than 0.1 per cent trifluoroacetic acid is added. If necessary, add propyl alcohol or isopropyl alcohol to solubilise the digest components, provided that the addition does not unduly increase the viscosity of the components.

Mobile phase. Buffered mobile phases containing phosphate are used to provide some flexibility in the selection of pH conditions, since shifts of pH in the 3.0-5.0 range enhance the separation of peptides containing acidic residues (e.g. glutamic and aspartic acids). Sodium or potassium phosphates, ammonium acetate, phosphoric acid at a pH between 2 and 7 (or higher for polymer-based supports) have also been used with acetonitrile gradients. Acetonitrile containing trifluoroacetic acid is used quite often.

Gradient. Gradients can be linear, nonlinear, or include step functions. A shallow gradient is recommended in order to separate complex mixtures. Gradients are optimised to provide clear resolution of 1 or 2 peaks that will become "marker" peaks for the test.

Isocratic elution. Isocratic HPLC systems using a single mobile phase are used on the basis of their convenience of use and improved detector responses. Optimal composition of a mobile phase to obtain clear resolution of each peak is sometimes difficult to establish. Mobile phases for which slight changes in component ratios or in pH significantly affect retention times of peaks in peptide maps must not be used in isocratic HPLC systems.

Other parameters. Temperature control of the column is usually necessary to achieve good reproducibility. The flow rates for the mobile phases range from 0.1-2.0 ml/min, and the detection of peptides is performed with a UV detector at 200-230 nm. Other methods of detection have been used (e.g. post-column derivatisation), but they are not as robust or versatile as UV detection.

Validation. This section provides an experimental means for measuring the overall performance of the test method. The acceptance criteria for system suitability depend on the identification of critical test parameters that affect data interpretation and acceptance. These critical parameters are also criteria that monitor peptide digestion and peptide analysis. An indicator that the desired digestion endpoint has been achieved is shown by comparison with a reference standard, which is treated in the same manner as the test protein. The use of a reference substance in parallel with the test protein is critical in the development and establishment of system suitability limits. In addition, a specimen chromatogram is included with the reference substance for additional comparison purposes. Other indicators may include visual inspection of protein or peptide solubility, the absence of intact protein, or measurement of responses of a digestion-dependent peptide. The critical system suitability parameters for peptide analysis will depend on the particular mode of peptide separation and detection and on the data analysis requirements.

When peptide mapping is used as an identification test, the system suitability requirements for the identified peptides cover selectivity and precision. In this case, as well as when identification of variant protein is done, the identification of the primary structure of the peptide fragments in the peptide map provides both a verification of the known primary structure and the identification of protein variants by comparison with the peptide map of the reference substance for the specified protein. The use of a digested reference substance for a given protein in the determination of peptide resolution is the method of choice. For an analysis of a variant protein, a characterised mixture of a variant and a reference substance can be used, especially if the variant peptide is located in a less-resolved region of the map. The index of pattern consistency can be simply the number of major peptides detected. Peptide pattern consistency can be best defined by the resolution of peptide peaks. Chromatographic parameters, such as peak-to-peak resolution, maximum peak width, peak area, peak tailing factors, and column efficiency, may be used to define peptide resolution. Depending on the protein under test and the method of separation used, single peptide or multiple peptide resolution requirements may be necessary.

The replicate analysis of the digest of the reference substance for the protein under test yields measures of precision and quantitative recovery. Recovery of the identified peptides is generally ascertained by the use of internal or external peptide standards. The precision is expressed as the relative standard deviation (RSD). Differences in the recovery and precision of the identified peptides are to be expected; therefore, the system suitability limits will have to be established for both the recovery and the precision of the identified peptides. These limits are unique for a given protein and will be specified in the individual monograph.

Visual comparison of the relative retentions, the peak responses (the peak area or the peak height), the number of peaks, and the overall elution pattern is completed initially. It is then complemented and supported by mathematical analysis of the peak response ratios and by the chromatographic profile of a 1:1 (*V/V*) mixture of sample and reference substance digest. If all peaks in the sample digest and in the reference substance digest have the same relative retentions and peak response ratios, then the identity of the sample under test is confirmed.

If peaks that initially eluted with significantly different relative retentions are then observed as single peaks in the 1:1 mixture, the initial difference would be an indication of system variability. However, if separate peaks are observed in the 1:1 mixture, this would be evidence of the nonequivalence of the peptides in each peak. If a peak in the 1:1 mixture is significantly broader than the corresponding peak in the sample and reference substance digest, it may indicate the presence of different peptides. The use of computer-aided pattern recognition software for the analysis of peptide mapping data has been proposed and applied, but issues related to the validation of the computer software preclude its use in a compendial test in the near future. Other automated approaches have been

used that employ mathematical formulas, models, and pattern recognition. Such approaches are, for example, the automated identification of compounds by IR spectroscopy and the application of diode-array UV spectral analysis for identification of peptides. These methods have limitations due to inadequate resolutions, co-elution of fragments, or absolute peak response differences between reference substance and sample digest fragments.

The numerical comparison of the peak retention times and peak areas or peak heights can be done for a selected group of relevant peaks that have been correctly identified in the peptide maps. Peak areas can be calculated using 1 peak showing relatively small variation as an internal reference, keeping in mind that peak area integration is sensitive to baseline variation and likely to introduce error in the analysis. Alternatively, the percentage of each peptide peak height relative to the sum of all peak heights can be calculated for the sample under test. The percentage is then compared to that of the corresponding peak of the reference substance. The possibility of auto-hydrolysis of trypsin is monitored by producing a blank peptide map, that is, the peptide map obtained when a blank solution is treated with trypsin.

The minimum requirement for the qualification of peptide mapping is an approved test procedure that includes system suitability as a test control. In general, early in the regulatory process, qualification of peptide mapping for a protein is sufficient. As the regulatory approval process for the protein progresses, additional qualifications of the test can include a partial validation of the analytical procedure to provide assurance that the method will perform as intended in the development of a peptide map for the specified protein.

ANALYSIS AND IDENTIFICATION OF PEPTIDES

This section gives guidance on the use of peptide mapping during development in support of regulatory applications.

The use of a peptide map as a qualitative tool does not require the complete characterisation of the individual peptide peaks. However, validation of peptide mapping in support of regulatory applications requires rigorous characterisation of each of the individual peaks in the peptide map. Methods to characterise peaks range from *N*-terminal sequencing of each peak followed by amino acid analysis to the use of mass spectroscopy (MS).

For characterisation purposes, when *N*-terminal sequencing and amino acids analysis are used, the analytical separation is scaled up. Since scale-up might affect the resolution of peptide peaks, it is necessary, using empirical data, to assure that there is no loss of resolution due to scale-up. Eluates corresponding to specific peptide peaks are collected, vacuum-concentrated, and chromatographed again, if necessary. Amino acid analysis of fragments may be limited by the peptide size. If the *N*-terminus is blocked, it may need to be cleared before sequencing. *C*-terminal sequencing of proteins in combination with carboxypeptidase and matrix-assisted laser desorption ionisation coupled to time-of-flight analyser (MALDI-TOF) can also be used for characterisation purposes.

The use of MS for characterisation of peptide fragments is by direct infusion of isolated peptides or by the use of on-line LC-MS for structure analysis. In general, it includes electrospray and MALDI-TOF-MS, as well as fast-atom bombardment (FAB). Tandem MS has also been used to sequence a modified protein and to determine the type of amino acid modification that has occurred. The comparison of mass spectra of the digests before and after reduction provides a method to assign the disulphide bonds to the various sulphydryl-containing peptides.

If regions of the primary structure are not clearly demonstrated by the peptide map, it might be necessary to develop a secondary peptide map. The goal of a validated method of characterisation of a protein through peptide mapping is to reconcile and account for at least 95 per cent of the theoretical composition of the protein structure.

01/2008:20256

2.2.56. AMINO ACID ANALYSIS

Amino acid analysis refers to the methodology used to determine the amino acid composition or content of proteins, peptides, and other pharmaceutical preparations. Proteins and peptides are macromolecules consisting of covalently bonded amino acid residues organised as a linear polymer. The sequence of the amino acids in a protein or peptide determines the properties of the molecule. Proteins are considered large molecules that commonly exist as folded structures with a specific conformation, while peptides are smaller and may consist of only a few amino acids. Amino acid analysis can be used to quantify proteins and peptides, to determine the identity of proteins or peptides based on their amino acid composition, to support protein and peptide structure analysis, to evaluate fragmentation strategies for peptide mapping, and to detect atypical amino acids that might be present in a protein or peptide. It is necessary to hydrolyse a protein/peptide to its individual amino acid constituents before amino acid analysis. Following protein/peptide hydrolysis, the amino acid analysis procedure can be the same as that practiced for free amino acids in other pharmaceutical preparations. The amino acid constituents of the test sample are typically derivatised for analysis.

APPARATUS

Methods used for amino acid analysis are usually based on a chromatographic separation of the amino acids present in the test sample. Current techniques take advantage of the automated chromatographic instrumentation designed for analytical methodologies. An amino acid analysis instrument will typically be a low-pressure or high-pressure liquid chromatograph capable of generating mobile phase gradients that separate the amino acid analytes on a chromatographic column. The instrument must have post-column derivatisation capability, unless the sample is analysed using precolumn derivatisation. The detector is usually an ultraviolet/visible or fluorescence detector depending on the derivatisation method used. A recording device (e.g., integrator) is used for transforming the analogue signal from the detector and for quantitation. It is preferred that instrumentation be dedicated particularly for amino acid analysis.

GENERAL PRECAUTIONS

Background contamination is always a concern for the analyst in performing amino acid analysis. High purity reagents are necessary (e.g., low purity hydrochloric acid can contribute to glycine contamination). Analytical reagents are changed routinely every few weeks using only high-pressure liquid chromatography (HPLC) grade solvents. Potential microbial contamination and foreign material that might be present in the solvents are reduced by filtering solvents before use, keeping solvent reservoirs covered, and not placing amino acid analysis instrumentation in direct sunlight.

Laboratory practices can determine the quality of the amino acid analysis. Place the instrumentation in a low traffic area of the laboratory. Keep the laboratory clean. Clean and

calibrate pipets according to a maintenance schedule. Keep pipet tips in a covered box; the analysts may not handle pipet tips with their hands. The analysts may wear powder-free latex or equivalent gloves. Limit the number of times a test sample vial is opened and closed because dust can contribute to elevated levels of glycine, serine, and alanine.

A well-maintained instrument is necessary for acceptable amino acid analysis results. If the instrument is used on a routine basis, it is to be checked daily for leaks, detector and lamp stability, and the ability of the column to maintain resolution of the individual amino acids. Clean or replace all instrument filters and other maintenance items on a routine schedule.

REFERENCE MATERIAL

Acceptable amino acid standards are commercially available for amino acid analysis and typically consist of an aqueous mixture of amino acids. When determining amino acid composition, protein or peptide standards are analysed with the test material as a control to demonstrate the integrity of the entire procedure. Highly purified bovine serum albumin has been used as a protein standard for this purpose.

CALIBRATION OF INSTRUMENTATION

Calibration of amino acid analysis instrumentation typically involves analysing the amino acid standard, which consists of a mixture of amino acids at a number of concentrations, to determine the response factor and range of analysis for each amino acid. The concentration of each amino acid in the standard is known. In the calibration procedure, the analyst dilutes the amino acid standard to several different analyte levels within the expected linear range of the amino acid analysis technique. Then, replicates at each of the different analyte levels can be analysed. Peak areas obtained for each amino acid are plotted versus the known concentration for each of the amino acids in the standard dilution. These results will allow the analyst to determine the range of amino acid concentrations where the peak area of a given amino acid is an approximately linear function of the amino acid concentration. It is important that the analyst prepare the samples for amino acid analysis so that they are within the analytical limits (e.g., linear working range) of the technique employed in order to obtain accurate and repeatable results.

4 to 6 amino acid standard levels are analysed to determine a response factor for each amino acid. The response factor is calculated as the average peak area or peak height per nanomole of amino acid present in the standard. A calibration file consisting of the response factor for each amino acid is prepared and used to calculate the concentration of each amino acid present in the test sample. This calculation involves dividing the peak area corresponding to a given amino acid by the response factor for that amino acid to give the nanomoles of the amino acid. For routine analysis, a single-point calibration may be sufficient; however, the calibration file is updated frequently and tested by the analysis of analytical controls to ensure its integrity.

REPEATABILITY

Consistent high quality amino acid analysis results from an analytical laboratory require attention to the repeatability of the assay. During analysis of the chromatographic separation of the amino acids or their derivatives, numerous peaks can be observed on the chromatogram that correspond to the amino acids. The large number of peaks makes it necessary to have an amino acid analysis system that can repeatedly identify the peaks based on retention time and integrate the peak areas for quantitation. A typical repeatability evaluation involves preparing a standard amino acid solution and analysing many replicates (e.g., 6 analyses or more) of the same standard solution. The relative standard deviation (RSD) is determined for the retention time and integrated peak area of each amino acid. An evaluation of the repeatability is expanded to include multiple assays conducted over several days by different analysts. Multiple assays include the preparation of standard dilutions from starting materials to determine the variation due to sample handling. The amino acid composition of a standard protein (e.g., bovine serum albumin) is often analysed as part of the repeatability evaluation. By evaluating the replicate variation (i.e., RSD), the laboratory can establish analytical limits to ensure that the analyses from the laboratory are under control. It is desirable to establish the lowest practical variation limits to ensure the best results. Areas to focus on to lower the variability of the amino acid analysis include sample preparation, high background spectral interference due to quality of reagents and/or laboratory practices, instrument performance and maintenance, data analysis and interpretation, and analyst performance and habits. All parameters involved are fully investigated in the scope of the validation work.

SAMPLE PREPARATION

Accurate results from amino acid analysis require purified protein and peptide samples. Buffer components (e.g., salts, urea, detergents) can interfere with the amino acid analysis and are removed from the sample before analysis. Methods that utilise post-column derivatisation of the amino acids are generally not affected by buffer components to the extent seen with pre-column derivatisation methods. It is desirable to limit the number of sample manipulations to reduce potential background contamination, to improve analyte recovery, and to reduce labour. Common techniques used to remove buffer components from protein samples include the following methods: (1) injecting the protein sample onto a reversed-phase HPLC system, removing the protein with a volatile solvent containing a sufficient organic component, and drying the sample in a vacuum centrifuge; (2) dialysis against a volatile buffer or water; (3) centrifugal ultrafiltration for buffer replacement with a volatile buffer or water; (4) precipitating the protein from the buffer using an organic solvent (e.g., acetone); (5) gel filtration.

INTERNAL STANDARDS

It is recommended that an internal standard be used to monitor physical and chemical losses and variations during amino acid analysis. An accurately known amount of internal standard can be added to a protein solution prior to hydrolysis. The recovery of the internal standard gives the general recovery of the amino acids of the protein solution. Free amino acids, however, do not behave in the same way as protein-bound amino acids during hydrolysis, whose rates of release or destruction are variable. Therefore, the use of an internal standard to correct for losses during hydrolysis may give unreliable results. It will be necessary to take this point into consideration when interpreting the results. Internal standards can also be added to the mixture of amino acids after hydrolysis to correct for differences in sample application and changes in reagent stability and flow rates. Ideally, an internal standard is an unnaturally occurring primary amino acid that is commercially available and inexpensive. It should also be stable during hydrolysis, its response factor should be linear with concentration, and it needs to elute with a unique retention time without overlapping other amino acids. Commonly used amino acid standards include norleucine, nitrotyrosine, and α-aminobutyric acid.

PROTEIN HYDROLYSIS

Hydrolysis of protein and peptide samples is necessary for amino acid analysis of these molecules. The glassware used for hydrolysis must be very clean to avoid erroneous results. Glove powders and fingerprints on hydrolysis tubes may cause contamination. To clean glass hydrolysis tubes, boil tubes for 1 h in 1 M hydrochloric acid or soak tubes in concentrated nitric acid or in a mixture of equal volumes of concentrated hydrochloric acid and nitric acid. Clean hydrolysis tubes are rinsed with high-purity water followed by a rinse with HPLC grade methanol, dried overnight in an oven, and stored covered until use. Alternatively, pyrolysis of clean glassware at 500 °C for 4 h may also be used to eliminate contamination from hydrolysis tubes. Adequate disposable laboratory material can also be used.

Acid hydrolysis is the most common method for hydrolysing a protein sample before amino acid analysis. The acid hydrolysis technique can contribute to the variation of the analysis due to complete or partial destruction of several amino acids: tryptophan is destroyed; serine and threonine are partially destroyed; methionine might undergo oxidation; and cysteine is typically recovered as cystine (but cystine recovery is usually poor because of partial destruction or reduction to cysteine). Application of adequate vacuum (less than 200 µm of mercury or 26.7 Pa) or introduction of an inert gas (argon) in the headspace of the reaction vessel can reduce the level of oxidative destruction. In peptide bonds involving isoleucine and valine the amido bonds of Ile-Ile, Val-Val, Ile-Val, and Val-Ile are partially cleaved; and asparagine and glutamine are deamidated, resulting in aspartic acid and glutamic acid, respectively. The loss of tryptophan, asparagine, and glutamine during an acid hydrolysis limits quantitation to 17 amino acids. Some of the hydrolysis techniques described are used to address these concerns. Some of the hydrolysis techniques described (i.e., Methods 4-11) may cause modifications to other amino acids. Therefore, the benefits of using a given hydrolysis technique are weighed against the concerns with the technique and are tested adequately before employing a method other than acid hydrolysis.

A time-course study (i.e., amino acid analysis at acid hydrolysis times of 24 h, 48 h and 72 h) is often employed to analyse the starting concentration of amino acids that are partially destroyed or slow to cleave. By plotting the observed concentration of labile amino acids (e.g., serine and threonine) versus hydrolysis time, the line can be extrapolated to the origin to determine the starting concentration of these amino acids. Time-course hydrolysis studies are also used with amino acids that are slow to cleave (e.g., isoleucine and valine). During the hydrolysis time course, the analyst will observe a plateau in these residues. The level of this plateau is taken as the residue concentration. If the hydrolysis time is too long, the residue concentration of the sample will begin to decrease, indicating destruction by the hydrolysis conditions.

An acceptable alternative to the time-course study is to subject an amino acid calibration standard to the same hydrolysis conditions as the test sample. The amino acid in free form may not completely represent the rate of destruction of labile amino acids within a peptide or protein during the hydrolysis. This is especially true for peptide bonds that are slow to cleave (e.g., Ile-Val bonds). However, this technique will allow the analyst to account for some residue destruction. Microwave acid hydrolysis has been used and is rapid but requires special equipment as well as special precautions. The optimal conditions for microwave hydrolysis must be investigated for each individual protein/peptide sample. The microwave hydrolysis technique typically requires only a few minutes, but even a deviation of one minute may give inadequate results (e.g., incomplete hydrolysis or destruction of labile amino acids). Complete proteolysis, using a mixture of proteases, has been used but can be complicated, requires the proper controls, and is typically more applicable to peptides than proteins.

During initial analyses of an unknown protein, experiments with various hydrolysis time and temperature conditions are conducted to determine the optimal conditions.

METHOD 1

Acid hydrolysis using hydrochloric acid containing phenol is the most common procedure used for protein/peptide hydrolysis preceding amino acid analysis. The addition of phenol to the reaction prevents the halogenation of tyrosine.

Hydrolysis solution. 6 M hydrochloric acid containing 0.1 per cent to 1.0 per cent of phenol.

Procedure

Liquid phase hydrolysis. Place the protein or peptide sample in a hydrolysis tube, and dry (the sample is dried so that water in the sample will not dilute the acid used for the hydrolysis). Add 200 µl of hydrolysis solution per 500 µg of lyophilised protein. Freeze the sample tube in a dry ice-acetone bath, and flame seal *in vacuo*. Samples are typically hydrolysed at 110 °C for 24 h *in vacuo* or in an inert atmosphere to prevent oxidation. Longer hydrolysis times (e.g., 48 h and 72 h) are investigated if there is a concern that the protein is not completely hydrolysed.

Vapour phase hydrolysis. This is one of the most common acid hydrolysis procedures, and it is preferred for microanalysis when only small amounts of the sample are available. Contamination of the sample from the acid reagent is also minimised by using vapour phase hydrolysis. Place vials containing the dried samples in a vessel that contains an appropriate amount of hydrolysis solution. The hydrolysis solution does not come in contact with the test sample. Apply an inert atmosphere or vacuum (less than 200 µm of mercury or 26.7 Pa) to the headspace of the vessel, and heat to about 110 °C for a 24 h hydrolysis time. Acid vapour hydrolyses the dried sample. Any condensation of the acid in the sample vials is to be minimised. After hydrolysis, dry the test sample *in vacuo* to remove any residual acid.

METHOD 2

Tryptophan oxidation during hydrolysis is decreased by using mercaptoethanesulfonic acid as the reducing acid.

Hydrolysis solution. 2.5 M mercaptoethanesulfonic acid solution.

Vapour phase hydrolysis. Dry about 1 µg to 100 µg of the protein/peptide under test in a hydrolysis tube. Place the hydrolysis tube in a larger tube with about 200 µl of the hydrolysis solution. Seal the larger tube *in vacuo* (about 50 µm of mercury or 6.7 Pa) to vaporise the hydrolysis solution. Heat the hydrolysis tube to 170-185 °C for about 12.5 min. After hydrolysis, dry the hydrolysis tube *in vacuo* for 15 min to remove the residual acid.

METHOD 3

Tryptophan oxidation during hydrolysis is prevented by using thioglycollic acid (TGA) as the reducing acid.

Hydrolysis solution. 7 M hydrochloric acid containing 1 per cent of phenol, 10 per cent of trifluoroacetic acid and 20 per cent of thioglycollic acid.

Vapour phase hydrolysis. Dry about 10 µg to 50 µg of the protein/peptide under test in a sample tube. Place the sample tube in a larger tube with about 200 µl of the hydrolysis solution. Seal the larger tube *in vacuo* (about 50 µm of mercury or 6.7 Pa) to vaporise the TGA. Heat the

sample tube to 166 °C for about 15-30 min. After hydrolysis, dry the sample tube *in vacuo* for 5 min to remove the residual acid. Recovery of tryptophan by this method may be dependent on the amount of sample present.

METHOD 4

Cysteine/cystine and methionine oxidation is performed with performic acid before the protein hydrolysis.

Oxidation solution. Use performic acid freshly prepared by mixing 1 volume of hydrogen peroxide solution (30 per cent) and 9 volumes of anhydrous formic acid and incubating at room temperature for 1 h.

Procedure. Dissolve the protein/peptide sample in 20 µl of anhydrous formic acid and heat at 50 °C for 5 min; then add 100 µl of the oxidation solution. Allow the oxidation to proceed for 10-30 min. In this reaction, cysteine is converted to cysteic acid and methionine is converted to methionine-sulphone. Remove the excess reagent from the sample in a vacuum centrifuge. The oxidised protein can then be acid hydrolysed using Method 1 or Method 2. This technique may cause modifications to tyrosine residues in the presence of halides.

METHOD 5

Cysteine/cystine oxidation is accomplished during the liquid phase hydrolysis with sodium azide.

Hydrolysis solution. To 6 M hydrochloric acid containing 0.2 per cent of phenol, add sodium azide to obtain a final concentration of 2 g/l. The added phenol prevents halogenation of tyrosine.

Liquid phase hydrolysis. Conduct the protein/peptide hydrolysis at about 110 °C for 24 h. During the hydrolysis, the cysteine/cystine present in the sample is converted to cysteic acid by the sodium azide present in the hydrolysis solution. This technique allows better tyrosine recovery than Method 4, but it is not quantitative for methionine. Methionine is converted to a mixture of the parent methionine and its 2 oxidative products, methionine-sulphoxide and methionine-sulphone.

METHOD 6

Cysteine/cystine oxidation is accomplished with dimethyl sulphoxide (DMSO).

Hydrolysis solution. To 6 M hydrochloric acid containing 0.1 per cent to 1.0 per cent of phenol, add dimethyl sulphoxide to obtain a final concentration of 2 per cent *V/V*.

Vapour phase hydrolysis. Conduct the protein/peptide hydrolysis at about 110 °C for 24 h. During the hydrolysis, the cysteine/cystine present in the sample is converted to cysteic acid by the DMSO present in the hydrolysis solution. As an approach to limit variability and compensate for partial destruction, it is recommended to evaluate the cysteic acid recovery from oxidative hydrolysis of standard proteins containing 1-8 mol of cysteine. The response factors from protein/peptide hydrolysates are typically about 30 per cent lower than those for non-hydrolysed cysteic acid standards. Because histidine, methionine, tyrosine, and tryptophan are also modified, a complete compositional analysis is not obtained with this technique.

METHOD 7

Cysteine/cystine reduction and alkylation is accomplished by a vapour phase pyridylethylation reaction.

Reducing solution. Transfer 83.3 µl of pyridine, 16.7 µl of 4-vinylpyridine, 16.7 µl of tributylphosphine, and 83.3 µl of water to a suitable container and mix.

Procedure. Add the protein/peptide (between 1 and 100 µg) to a hydrolysis tube, and place in a larger tube. Transfer the reducing solution to the large tube, seal *in vacuo* (about 50 µm of mercury or 6.7 Pa), and heat at about 100 °C for 5 min. Then remove the inner hydrolysis tube, and dry it in a vacuum desiccator for 15 min to remove residual reagents. The pyridylethylated sample can then be acid hydrolysed using previously described procedures. The pyridylethylation reaction is performed simultaneously with a protein standard sample containing 1-8 mol of cysteine to evaluate the pyridylethyl-cysteine recovery. Longer incubation times for the pyridylethylation reaction can cause modifications to the α-amino terminal group and the ϵ-amino group of lysine in the protein.

METHOD 8

Cysteine/cystine reduction and alkylation is accomplished by a liquid phase pyridylethylation reaction.

Stock solutions. Prepare and filter 3 solutions: 1 M Tris-hydrochloride pH 8.5 containing 4 mM disodium edetate (stock solution A), 8 M guanidine hydrochloride (stock solution B), and 10 per cent of 2-mercaptoethanol (stock solution C).

Reducing solution. Prepare a mixture of 1 volume of stock solution A and 3 volumes of stock solution B to obtain a buffered solution of 6 M guanidine hydrochloride in 0.25 M tris-hydrochloride.

Procedure. Dissolve about 10 µg of the test sample in 50 µl of the reducing solution, and add about 2.5 µl of stock solution C. Store under nitrogen or argon for 2 h at room temperature in the dark. To achieve the pyridylethylation reaction, add about 2 µl of 4-vinylpyridine to the protein solution, and incubate for an additional 2 h at room temperature in the dark. Desalt the protein/peptide by collecting the protein/peptide fraction from a reversed-phase HPLC separation. The collected sample can be dried in a vacuum centrifuge before acid hydrolysis.

METHOD 9

Cysteine/cystine reduction and alkylation is accomplished by a liquid phase carboxymethylation reaction.

Stock solutions. Prepare as directed for Method 8.

Carboxymethylation solution. Prepare a 100 g/l solution of iodoacetamide in alcohol.

Buffer solution. Use the reducing solution, prepared as described for Method 8.

Procedure. Dissolve the test sample in 50 µl of the buffer solution, and add about 2.5 µl of stock solution C. Store under nitrogen or argon for 2 h at room temperature in the dark. Add the carboxymethylation solution in a ratio 1.5 fold per total theoretical content of thiols, and incubate for an additional 30 min at room temperature in the dark. If the thiol content of the protein is unknown, then add 5 µl of 100 mM iodoacetamide for every 20 nmol of protein present. The reaction is stopped by adding excess of 2-mercaptoethanol. Desalt the protein/peptide by collecting the protein/peptide fraction from a reversed-phase HPLC separation. The collected sample can be dried in a vacuum centrifuge before acid hydrolysis. The *S*-carboxyamidomethyl-cysteine formed will be converted to *S*-carboxymethyl-cysteine during acid hydrolysis.

METHOD 10

Cysteine/cystine is reacted with dithiodiglycolic acid or dithiodipropionic acid to produce a mixed disulphide. The choice of dithiodiglycolic acid or dithiodipropionic acid depends on the required resolution of the amino acid analysis method.

Reducing solution. A 10 g/l solution of dithiodiglycolic acid (or dithiodipropionic acid) in 0.2 M sodium hydroxide.

Procedure. Transfer about 20 µg of the test sample to a hydrolysis tube, and add 5 µl of the reducing solution. Add 10 µl of isopropyl alcohol, and then remove all of the sample liquid by vacuum centrifugation. The sample is then hydrolysed using Method 1. This method has the advantage that other amino acid residues are not derivatised by side reactions, and that the sample does not need to be desalted prior to hydrolysis.

METHOD 11

Asparagine and glutamine are converted to aspartic acid and glutamic acid, respectively, during acid hydrolysis. Asparagine and aspartic acid residues are added and represented by *Asx*, while glutamine and glutamic acid residues are added and represented by *Glx*. Proteins/peptides can be reacted with bis(1,1-trifluoroacetoxy)iodobenzene (BTI) to convert the asparagine and glutamine residues to diaminopropionic acid and diaminobutyric acid residues, respectively, upon acid hydrolysis. These conversions allow the analyst to determine the asparagine and glutamine content of a protein/peptide in the presence of aspartic acid and glutamic acid residues.

Reducing solutions. Prepare and filter 3 solutions: a solution of 10 mM trifluoroacetic acid (Solution A), a solution of 5 M guanidine hydrochloride and 10 mM trifluoroacetic acid (Solution B), and a freshly prepared solution of dimethylformamide containing 36 mg of BTI per millilitre (Solution C).

Procedure. In a clean hydrolysis tube, transfer about 200 µg of the test sample, and add 2 ml of Solution A or Solution B and 2 ml of Solution C. Seal the hydrolysis tube *in vacuo*. Heat the sample at 60 °C for 4 h in the dark. The sample is then dialysed with water to remove the excess reagents. Extract the dialysed sample 3 times with equal volumes of butyl acetate, and then lyophilise. The protein can then be acid hydrolysed using previously described procedures. The α,β-diaminopropionic and α,γ-diaminobutyric acid residues do not typically resolve from the lysine residues upon ion-exchange chromatography based on amino acid analysis. Therefore, when using ion-exchange as the mode of amino acid separation, the asparagine and glutamine contents are the quantitative difference in the aspartic acid and glutamic acid content assayed with underivatised and BTI-derivatised acid hydrolysis. The threonine, methionine, cysteine, tyrosine, and histidine assayed content can be altered by BTI derivatisation; a hydrolysis without BTI will have to be performed if the analyst is interested in the composition of these other amino acid residues of the protein/peptide.

METHODOLOGIES OF AMINO ACID ANALYSIS: GENERAL PRINCIPLES

Many amino acid analysis techniques exist, and the choice of any one technique often depends on the sensitivity required from the assay. In general, about one-half of the amino acid analysis techniques employed rely on the separation of the free amino acids by ion-exchange chromatography followed by post-column derivatisation (e.g., with ninhydrin or *o*-phthalaldehyde). Post-column derivatisation techniques can be used with samples that contain small amounts of buffer components, (such as salts and urea) and generally require between 5 µg and 10 µg of protein sample per analysis. The remaining amino acid techniques typically involve pre-column derivatisation of the free amino acids (e.g., phenyl isothiocyanate; 6-aminoquinolyl-*N*-hydroxysuccinimidyl carbamate or *o*-phthalaldehyde; (dimethylamino)azobenzenesulphonyl chloride; 9-fluorenylmethyl chloroformate; and 7-fluoro-4-nitrobenzo-2-oxa-1,3-diazole) followed by reversed-phase HPLC. Pre-column derivatisation techniques are very sensitive and usually require between 0.5 µg and 1.0 µg of protein sample per analysis but may be influenced by buffer salts in the samples. Pre-column derivatisation techniques may also result in multiple derivatives of a given amino acid, which complicates the result interpretation. Post-column derivatisation techniques are generally influenced less by performance variation of the assay than pre-column derivatisation techniques.

The following methods may be used for quantitative amino acid analysis. Instruments and reagents for these procedures are available commercially. Furthermore, many modifications of these methodologies exist with different reagent preparations, reaction procedures, chromatographic systems, etc. Specific parameters may vary according to the exact equipment and procedure used. Many laboratories will use more than one amino acid analysis technique to exploit the advantages offered by each. In each of these methods, the analogue signal is visualised by means of a data acquisition system, and the peak areas are integrated for quantification purposes.

METHOD 1 - POST-COLUMN NINHYDRIN DERIVATISATION

Ion-exchange chromatography with post-column ninhydrin derivatisation is one of the most common methods employed for quantitative amino acid analysis. As a rule, a lithium-based cation-exchange system is employed for the analysis of the more complex physiological samples, and the faster sodium-based cation-exchange system is used for the more simplistic amino acid mixtures obtained with protein hydrolysates (typically containing 17 amino acid components). Separation of the amino acids on an ion-exchange column is accomplished through a combination of changes in pH and cation strength. A temperature gradient is often employed to enhance separation.

When the amino acid reacts with ninhydrin, the reactant has a characteristic purple or yellow colour. Amino acids, except imino acid, give a purple colour, and show an absorption maximum at 570 nm. The imino acids such as proline give a yellow colour, and show an absorption maximum at 440 nm. The post-column reaction between ninhydrin and amino acids eluted from the column is monitored at 440 nm and 570 nm, and the chromatogram obtained is used for the determination of amino acid composition.

The detection limit is considered to be 10 pmol for most of the amino acid derivatives, but 50 pmol for the proline derivative. Response linearity is obtained in the range of 20-500 pmol with correlation coefficients exceeding 0.999. To obtain good composition data, samples larger than 1 µg before hydrolysis are best suited for this amino acid analysis of protein/peptide.

METHOD 2 - POST-COLUMN OPA DERIVATISATION

o-Phthalaldehyde (OPA) reacts with primary amines in the presence of thiol compound, to form highly fluorescent isoindole products. This reaction is used for the post-column derivatisation in analysis of amino acids by ion-exchange chromatography. The rule of the separation is the same as Method 1.

Although OPA does not react with secondary amines (imino acids such as proline) to form fluorescent substances, the oxidation with sodium hypochlorite or chloramine T allows secondary amines to react with OPA. The procedure employs a strongly acidic cation-exchange column for separation of free amino acids followed by post-column oxidation with sodium hypochlorite or chloramine T and post-column derivatisation using OPA and a thiol compound such as

N-acetyl-L-cysteine or 2-mercaptoethanol. The derivatisation of primary amino acids is not noticeably affected by the continuous supply of sodium hypochlorite or chloramine T.

Separation of the amino acids on an ion-exchange column is accomplished through a combination of changes in pH and cation strength. After post-column derivatisation of eluted amino acids with OPA, the reactant passes through the fluorometric detector. Fluorescence intensity of OPA-derivatised amino acids are monitored with an excitation wavelength of 348 nm and an emission wavelength of 450 nm.

The detection limit is considered to be a few tens of picomole level for most of the OPA-derivatised amino acids. Response linearity is obtained in the range of a few picomole level to a few tens of nanomole level. To obtain good compositional data, samples larger than 500 ng of protein/peptide before hydrolysis are recommended.

METHOD 3 - PRE-COLUMN PITC DERIVATISATION

Phenylisothiocyanate (PITC) reacts with amino acids to form phenylthiocarbamyl (PTC) derivatives which can be detected with high sensitivity at 254 nm. Therefore, pre-column derivatisation of amino acids with PITC followed by a reversed-phase HPLC separation with UV detection is used to analyse the amino acid composition.

After the reagent is removed under vacuum, the derivatised amino acids can be stored dry and frozen for several weeks with no significant degradation. If the solution for injection is kept cold, no noticeable loss in chromatographic response occurs after 3 days.

Separation of the PTC-amino acids on a reversed-phase HPLC with an octadecylsilyl (ODS) column is accomplished through a combination of changes in concentrations of acetonitrile and buffer ionic strength. PTC-amino acids eluted from the column are monitored at 254 nm.

The detection limit is considered to be 1 pmol for most of the PTC-amino acids. Response linearity is obtained in the range of 20-500 pmol with correlation coefficients exceeding 0.999. To obtain good compositional data, samples larger than 500 ng of protein/peptide before hydrolysis are recommended.

METHOD 4 - PRE-COLUMN AQC DERIVITISATION

Pre-column derivatisation of amino acids with 6-aminoquinolyl-*N*-hydroxysuccinimidyl carbamate (AQC) followed by reversed-phase HPLC separation with fluorometric detection is used.

AQC reacts with amino acids to form stable, fluorescent unsymmetric urea derivatives (AQC-amino acids) which are readily amenable to analysis by reversed-phase HPLC. Therefore, pre-column derivatisation of amino acids with AQC followed by reversed-phase HPLC separation with fluorimetric detection is used to analyse the amino acid composition.

Separation of the AQC-amino acids on a reversed-phase HPLC with an ODS column is accomplished through a combination of changes in concentrations of acetonitrile and buffer ionic strengh. Selective fluorescence detection of the derivatives with an excitation wavelength at 250 nm and an emission wavelength at 395 nm allows for the direct injection of the reaction mixture with no significant interference from the only major fluorescent reagent by-product, 6-aminoquinoline. Excess reagent is rapidly hydrolysed ($t_{1/2}$<15 s) to yield 6-aminoquinoline, *N*-hydroxysuccinimide and carbon dioxide, and after 1 min no further derivatisation can take place.

Peak areas for AQC-amino acids are essentially unchanged for at least 1 week at room temperature. Therefore AQC-amino acids have more than sufficient stability to allow for overnight automated chromatographic analysis.

The detection limit is considered to range from about 40 fmol to 320 fmol for each amino acid, except for cystein. The detection limit for cystein is approximately 800 fmol. Response linearity is obtained in the range of 2.5-200 µM with correlation coefficients exceeding 0.999. Good compositional data can be obtained from the analysis of derivatised protein hydrolysates derived from as little as 30 ng of protein/peptide.

METHOD 5 - PRE-COLUMN OPA DERIVATISATION

Pre-column derivatisation of amino acids with *o*-phthalaldehyde (OPA) followed by reversed-phase HPLC separation with fluorometric detection is used. This technique does not detect amino acids that exist as secondary amines (e.g., proline).

OPA in conjunction with a thiol reagent reacts with primary amine groups to form highly fluorescent isoindole products. 2-Mercaptoethanol or 3-mercaptopropionic acid can be used as the thiol. OPA itself does not fluoresce and consequently produces no interfering peaks. In addition, its solubility and stability in aqueous solution, along with the rapid kinetics for the reaction, make it amenable to automated derivatisation and analysis using an autosampler to mix the sample with the reagent. However, lack of reactivity with secondary amino acids has been a predominant drawback. This method does not detect amino acids that exist as secondary amines (e.g., proline). To compensate for this drawback, this technique may be combined with another technique described in Method 7 or Method 8.

Pre-column derivatisation of amino acids with OPA is followed by a reversed-phase HPLC separation. Because of the instability of the OPA-amino acid derivative, HPLC separation and analysis are performed immediately following derivatisation. The liquid chromatograph is equipped with a fluorometric detector for the detection of derivatised amino acids. Fluorescence intensity of OPA-derivatised amino acids is monitored with an excitation wavelength of 348 nm and an emission wavelength of 450 nm.

Detection limits as low as 50 fmol via fluorescence have been reported, although the practical limit of analysis remains at 1 pmol.

METHOD 6 - PRE-COLUMN DABS-Cl DERIVATISATION

Pre-column derivatisation of amino acids with (dimethylamino)azobenzenesulphonyl chloride (DABS-Cl) followed by reversed-phase HPLC separation with visible light detection is used.

DABS-Cl is a chromophoric reagent employed for the labelling of amino acids. Amino acids labelled with DABS-Cl (DABS-amino acids) are highly stable and show an absorption maximum at 436 nm.

DABS-amino acids, all naturally occurring amino acid derivatives, can be separated on an ODS column of a reversed-phase HPLC by employing gradient systems consisting of acetonitrile and aqueous buffer mixture. Separated DABS-amino acids eluted from the column are detected at 436 nm in the visible region.

This method can analyse the imino acids such as proline together with the amino acids at the same degree of sensitivity, DABS-Cl derivatisation method permits the simultaneous quantification of tryptophan residues by previous hydrolysis of the protein/peptide with sulphonic acids such as mercaptoethanesulphonic acid, *p*-toluenesulphonic acid or methanesulphonic acid described in Method 2 under Protein hydrolysis. The other

acid-labile residues, asparagine and glutamine, can also be analysed by previous conversion into diaminopropionic acid and diaminobutyric acid, respectively, by treatment of protein/peptide with BTI described in Method 11 under Protein hydrolysis.

The non-proteinogenic amino acid norleucine cannot be used as an internal standard in this method as this compound is eluted in a chromatographic region crowded with peaks of primary amino acids. Nitrotyrosine can be used as an internal standard because it is eluted in a clean region.

The detection limit of DABS-amino acid is about 1 pmol. As little as 2-5 pmol of an individual DABS-amino acid can be quantitatively analysed with reliability, and only 10-30 ng of the dabsylated protein hydrolysate is required for each analysis.

METHOD 7 - PRE-COLUMN FMOC-Cl DERIVATISATION

Pre-column derivatisation of amino acids with 9-fluorenylmethyl chloroformate (FMOC-Cl) followed by reversed-phase HPLC separation with fluorometric detection is used.

FMOC-Cl reacts with both primary and secondary amino acids to form highly fluorescent products. The reaction proceeds under mild conditions in aqueous solution and is completed in 30 s. The derivatives are stable, only the histidine derivative showing any breakdown. Although FMOC-Cl is fluorescent itself, the reagent excess and fluorescent side-products can be eliminated without loss of FMOC-amino acids.

FMOC-amino acids are separated by a reversed-phase HPLC using an ODS column. The separation is carried out by gradient elution varied linearly from a mixture of 10 volumes of acetonitrile, 40 volumes of methanol and 50 volumes of acetic acid buffer to a mixture of 50 volumes of acetonitrile and 50 volumes of acetic acid buffer and 20 amino acid derivatives are separated in 20 min. Each derivative eluted from the column is monitored by a fluorometric detector set at an excitation wavelength of 260 nm and an emission wavelength of 313 nm.

The detection limit is in the low femtomole range. A linearity range of 0.1-50 µM is obtained for most of the amino acids.

METHOD 8 - PRE-COLUMN NBD-F DERIVATISATION

Pre-column derivatisation of amino acids with 7-fluoro-4-nitrobenzo-2-oxa-1,3-diazole (NBD-F) followed by reversed-phase HPLC separation with fluorometric detection is used.

NBD-F reacts with both primary and secondary amino acids to form highly fluorescent products. Amino acids are derivatised with NBD-F by heating to 60 °C for 5 min.

NBD-amino acid derivatives are separated on an ODS column of a reversed-phase HPLC by employing a gradient elution system consisting of acetonitrile and aqueous buffer mixture, and 17 amino acid derivatives are separated in 35 min. ϵ-Aminocaproic acid can be used as an internal standard, because it is eluted in a clean chromatographic region. Each derivative eluted from the column is monitored by a fluorometric detector set at an excitation wavelength of 480 nm and an emission wavelength of 530 nm.

The sensitivity of this method is almost the same as for the pre-column OPA derivatisation method (Method 5), excluding proline to which OPA is not reactive, and might be advantageous for NBD-F against OPA. The detection limit for each amino acid is about 10 fmol. Profile analysis can be achieved with about 1.5 mg of protein hydrolysates in the pre-column reaction mixture.

DATA CALCULATION AND ANALYSIS

When determining the amino acid content of a protein/peptide hydrolysate, it should be noted that the acid hydrolysis step destroys tryptophan and cysteine. Serine and threonine are partially destroyed by acid hydrolysis, while isoleucine and valine residues may be only partially cleaved. Methionine can undergo oxidation during acid hydrolysis, and some amino acids (e.g., glycine and serine) are common contaminants. Application of adequate vacuum (less than 200 µm of mercury or 26.7 Pa) or introduction of inert gas (argon) in the headspace of the reaction vessel during vapour phase hydrolysis can reduce the level of oxidative destruction. Therefore, the quantitative results obtained for cysteine, tryptophan, threonine, isoleucine, valine, methionine, glycine, and serine from a protein/peptide hydrolysate may be variable and may warrant further investigation and consideration.

Amino Acid Mole Percent. This is the number of specific amino acid residues per 100 residues in a protein. This result may be useful for evaluating amino acid analysis data when the molecular mass of the protein under investigation is unknown. This information can be used to corroborate the identity of a protein/peptide and has other applications. Carefully identify and integrate the peaks obtained as directed for each procedure. Calculate the mole percent for each amino acid present in the test sample using the formula:

$$\frac{100 r_U}{r}$$

in which r_U is the peak response, in nanomoles, of the amino acid under test; and r is the sum of peak responses, in nanomoles, for all amino acids present in the test sample. Comparison of the mole percent of the amino acids under test to data from known proteins can help establish or corroborate the identity of the sample protein.

Unknown Protein Samples. This data analysis technique can be used to estimate the protein concentration of an unknown protein sample using the amino acid analysis data. Calculate the mass, in micrograms, of each recovered amino acid using the formula:

$$\frac{m M_r}{1000}$$

in which m is the recovered quantity, in nanomoles, of the amino acid under test; and M_r is the average molecular mass for that amino acid, corrected for the mass of the water molecule that was eliminated during peptide bond formation. The sum of the masses of the recovered amino acids will give an estimate of the total mass of the protein analysed after appropriate correction for partially and completely destroyed amino acids. If the molecular mass of the unknown protein is available (i.e., by SDS-PAGE analysis or mass spectroscopy), the amino acid composition of the unknown protein can be predicted. Calculate the number of residues of each amino acid using the formula:

$$\frac{m}{\left(\frac{1000 M}{M_{rt}}\right)}$$

in which m is the recovered quantity, in nanomoles, of the amino acid under test; M is the total mass, in micrograms, of the protein; and M_{rt} is the molecular mass of the unknown protein.

Known protein samples. This data analysis technique can be used to investigate the amino acid composition and protein concentration of a protein sample of known molecular mass and amino acid composition using the amino acid analysis

data. When the composition of the protein being analysed is known, one can exploit the fact that some amino acids are recovered well, while other amino acid recoveries may be compromised because of complete or partial destruction (e.g., tryptophan, cysteine, threonine, serine, methionine), incomplete bond cleavage (i.e., for isoleucine and valine) and free amino acid contamination (i.e., by glycine and serine).

Because those amino acids that are recovered best represent the protein, these amino acids are chosen to quantify the amount of protein. Well-recovered amino acids are, typically, aspartate-asparagine, glutamate-glutamine, alanine, leucine, phenylalanine, lysine, and arginine. This list can be modified based on experience with one's own analysis system. Divide the quantity, in nanomoles, of each of the well-recovered amino acids by the expected number of residues for that amino acid to obtain the protein content based on each well-recovered amino acid. Average the protein content results calculated. The protein content determined for each of the well-recovered amino acids should be evenly distributed about the mean. Discard protein content values for those amino acids that have an unacceptable deviation from the mean. Typically greater than 5 per cent variation from the mean is considered unacceptable. Recalculate the mean protein content from the remaining values to obtain the protein content of the sample. Divide the content of each amino acid by the calculated mean protein content to determine the amino acid composition of the sample by analysis.

Calculate the relative compositional error, in percentage, using the formula:

$$\frac{100m}{m_S}$$

in which m is the experimentally determined quantity, in nanomoles per amino acid residue, of the amino acid under test; and m_S is the known residue value for that amino acid. The average relative compositional error is the average of the absolute values of the relative compositional errors of the individual amino acids, typically excluding tryptophan and cysteine from this calculation. The average relative compositional error can provide important information on the stability of analysis run over time. The agreement in the amino acid composition between the protein sample and the known composition can be used to corroborate the identity and purity of the protein in the sample.

2.2.57. INDUCTIVELY COUPLED PLASMA-ATOMIC EMISSION SPECTROMETRY

GENERAL PRINCIPLE

Inductively coupled plasma-atomic emission spectrometry (ICP-AES) is an atomic emission spectrometry method that uses an inductively coupled plasma (ICP) as the excitation source.

An ICP is a highly ionised inert gas (usually argon) with equal numbers of electrons and ions sustained by a radio-frequency (RF) field. The high temperature reached in the plasma successively desolvates, vaporises, excites - atomic emission spectrometry (AES) detection - and ionises - mass spectrometry (MS) detection - atoms from the sample. Detection limits are, generally, in the lower nanogram (ICP-MS) to microgram (ICP-AES) per litre range.

The plasma is formed by a tangential stream of support gas through a 'torch', i.e. a system consisting of 3 concentric quartz tubes. A metal coil (the load coil) surrounds the top end of the torch and is connected to a radio-frequency (RF) generator. Power (usually 700-1500 W) is applied through the coil and an oscillating magnetic field corresponding to the frequency of the generator (in most cases 27 MHz, 40 MHz) is formed. The plasma forms when the support gas is made conductive by exposing it to an electric discharge, which produces seed electrons and ions. Inside the induced magnetic field, the charged particles (electrons and ions) are forced to flow in a closed annular path. As they meet resistance to their flow, heating takes place producing additional ionisation. The process occurs almost instantaneously, and the plasma expands to its full strength and dimensions. The radio-frequency oscillation of the power applied through the coil causes radio-frequency electric and magnetic fields to be set up in the area at the top of the torch. When a spark (produced by a Tesla tube or some other seeding device) is applied to the support gas flowing through the torch, some electrons are stripped from the support gas atoms. These electrons are then caught up in the magnetic field and accelerated. Adding energy to the electrons by the use of a coil is known as inductive coupling. These high-energy electrons in turn collide with other support-gas atoms, stripping off still more electrons. The collisional ionisation of the support gas continues in a chain reaction, breaking down the gas into a physical plasma consisting of support-gas atoms, electrons and support-gas ions. The plasma is then sustained within the torch and load coil as radio-frequency energy is continually transferred to it through the inductive coupling process.

The ICP appears as an intense, very bright, plume-shaped plasma. At the base the plasma is toroidal, and this is referred to as the induction region (IR), i.e. the region in which the inductive energy transfer from the load coil to the plasma takes place. The sample is introduced through the induction region into the centre of the plasma.

APPARATUS

The apparatus consists essentially of the following elements:

- sample-introduction system consisting of a peristaltic pump delivering the solution at constant flow rate into a nebuliser;
- radio-frequency (RF) generator;
- plasma torch;
- transfer optics focussing the image of the plasma at the entrance slit of the spectrometer; radial viewing is better for difficult matrices (alkalis, organics), whereas axial viewing gives more intensity and better detection limits in simple matrices;
- wavelength dispersive devices consisting of diffraction gratings, prisms, filters or interferometers;
- detectors converting radiant energy into electrical energy;
- data-acquisition unit.

INTERFERENCE

Interference is anything that causes the signal from an analyte in a sample to be different from the signal for the same concentration of that analyte in a calibration solution. The well-known chemical interference that is encountered in flame atomic absorption spectrometry is usually weak in ICP-AES. In rare cases where interference occurs, it may be necessary to increase the RF power or to reduce the inner support-gas flow to eliminate it. The interference in ICP-AES can be of spectral origin or even the result of high concentrations of certain elements or matrix compounds.

Physical interference (due to differences in viscosity and surface tension of the sample and calibration standards) can be minimised by dilution of the sample, matrix matching, use of internal standards or through application of the method of standard additions.

Another type of interference occasionally encountered in ICP-AES is the so-called 'easily ionised elements (EIEs) effect'. The EIEs are those elements that are ionised much more easily, for example alkaline metals and alkaline earths. In samples that contain high concentrations of EIEs (more than 0.1 per cent), suppression or enhancement of emission signals is likely to occur.

Spectral interference. This may be due to other lines or shifts in background intensity. These lines may correspond to argon (observed above 300 nm), OH bands due to the decomposition of water (at about 300 nm), NO bands due to the interaction of the plasma with the ambient air (between 200 nm and 300 nm), and other elements in the sample, especially those present at high concentrations. The interference falls into 4 different categories: simple background shift, sloping background shift, direct spectral overlap, and complex background shift.

Absorption interference. This arises when part of the emission from an analyte is absorbed before it reaches the detector. This effect is observed particularly when the concentration of a strongly emitting element is so high that the atoms or ions of that element that are in the lower energy state of transition absorb significant amounts of the radiation emitted by the relevant excited species. This effect, known as self-absorption, determines the upper end of the linear working range for a given emission line.

Multicomponent spectral fitting. Multiple emission-line determinations are commonly used to overcome problems with spectral interferences. A better, more accurate method for performing spectral interference corrections is to use the information obtained with advanced detector systems through multicomponent spectral fitting. This quantifies not only the interference, but also the background contribution from the matrix, thereby creating a correction formula. Multicomponent spectral fitting utilises a multiple linear-squares model based on the analysis of pure analyte, the matrix and the blank, creating an interference-corrected mathematical model. This permits the determination of the analyte emission in a complex matrix with improved detection limits and accuracy.

PROCEDURE

SAMPLE PREPARATION AND SAMPLE INTRODUCTION

The basic goal for the sample preparation is to ensure that the analyte concentration falls within the working range of the instrument through dilution or preconcentration, and that the sample-containing solution can be nebulised in a reproducible manner.

Several sample-introduction systems tolerate high acid concentrations, but the use of sulphuric and phosphoric acids can contribute to background emission observed in the ICP spectra. Therefore, nitric and hydrochloric acids are preferable. The availability of hydrofluoric acid-resistant (for example perfluoroalkoxy polymer) sample-introduction systems and torches also allows the use of hydrofluoric acid. In selecting a sample-introduction method, the requirements for sensitivity, stability, speed, sample size, corrosion resistance and resistance to clogging have to be considered. The use of a cross-flow nebuliser combined with a spray chamber and torch is suitable for most requirements. The peristaltic pumps used for ICP-AES usually deliver the standard and sample solutions at a rate of 1 ml/min or less.

In the case of organic solvents being used, the introduction of oxygen must be considered to avoid organic layers.

CHOICE OF OPERATING CONDITIONS

The standard operating conditions prescribed by the manufacturer are to be followed. Usually, different sets of operating conditions are used for aqueous solutions and for organic solvents. Suitable operating parameters are to be properly chosen:

- wavelength selection;
- support-gas flow rates (outer, intermediate and inner tubes of the torch);
- RF power;
- viewing position (radial or axial);
- pump speed;
- conditions for the detector (gain/voltage for photomultiplier tube detectors, others for array detectors);
- integration time (time set to measure the emission intensity at each wavelength).

CONTROL OF INSTRUMENT PERFORMANCE

System suitability

The following tests may be carried out with a multi-element control solution to ensure the adequate performance of the ICP-AES system:

- energy transfer (generator, torch, plasma); measurement of the ratio Mg II (280.270 nm)/Mg I (285.213 nm) may be used;
- sample transfer, by checking nebuliser efficiency and stability;
- resolution (optical system), by measuring peak widths at half height, for example As (189.042 nm), Mn (257.610 nm), Cu (324.754 nm) or Ba (455.403 nm);
- analytical performance, by calculating detection limits of selected elements over the wavelength range.

VALIDATION OF THE METHOD

Satisfactory performance of methods prescribed in monographs is verified at suitable time intervals.

LINEARITY

Prepare and analyse not fewer than 4 reference solutions over the calibration range plus a blank. Perform not fewer than 5 replicates.

The calibration curve is calculated by least-square regression from all measured data of the calibration test. The regression curve, the means, the measured data and the confidence interval of the calibration curve are plotted. The operating method is valid when:

- the correlation coefficient is at least 0.99;
- the residuals of each calibration level are randomly distributed around the calibration curve.

Calculate the mean and relative standard deviation for the lowest and for the highest calibration level.

When the ratio of the estimated standard deviations of the lowest and the highest calibration level is less than 0.5 or greater than 2.0, a more precise estimation of the calibration curve may be obtained using weighted linear regression. Both linear and quadratic weighting functions are applied to the data to find the most appropriate weighting function to be employed.

If the means compared to the calibration curve show a deviation from linearity, two-dimensional linear regression is used.

ACCURACY

Verify the accuracy preferably by using a certified reference material (CRM). Where this is not possible, perform a test for recovery.

Recovery. For assay determinations a recovery of 90 per cent to 110 per cent is to be obtained. The test is not valid if recovery, for example for trace-element determination, is outside of the range 80 per cent to 120 per cent of the theoretical value. Recovery may be determined on a suitable reference solution (matrix solution) spiked with a known quantity of analyte (concentration range that is relevant to the samples to be determined).

REPEATABILITY

The repeatability is not greater than 3 per cent for an assay and not greater than 5 per cent for an impurity test.

LIMIT OF QUANTIFICATION

Verify that the limit of quantification (for example, determined using the 10 σ approach) is below the value to be measured.

01/2008:20258

2.2.58. INDUCTIVELY COUPLED PLASMA-MASS SPECTROMETRY

Inductively coupled plasma-mass spectrometry (ICP-MS) is a mass spectrometry method that uses an inductively coupled plasma (ICP) as the ionisation source. The basic principles of ICP formation are described in chapter *2.2.57* on inductively coupled plasma-atomic emission spectrometry (ICP-AES).

ICP-MS utilises the ability of the ICP to generate charged ions from the element species within a sample. These ions are then directed into a mass spectrometer, which separates them according to their mass-to-charge ratio (*m/z*). Most mass spectrometers have a quadrupole system or a magnetic sector. Ions are transported from the plasma through 2 cones (sampler and skimmer cones, forming the interface region) to the ion optics. The ion optics consist of an electrostatic lens, which takes ions from an area at atmospheric pressure to the mass filter at a vacuum of 10^{-8} Pa or less, maintained with a turbomolecular pump. After their filtration, ions of the selected mass/charge ratio are directed to a detector (channel electromultiplier, Faraday cup, dynodes), where ion currents are converted into electrical signals. The element is quantified according to the number of ions arriving and generating electrical pulses per unit time.

The sample-introduction system and data-handling techniques of an ICP-AES system are also used in ICP-MS.

APPARATUS

The apparatus consists essentially of the following elements:

- sample-introduction system, consisting of a peristaltic pump delivering the solution at constant flow rate into a nebuliser;
- radio-frequency (RF) generator;
- plasma torch;
- interface region including cones to transport ions to the ion optics;
- mass spectrometer;
- detector;
- data-acquisition unit.

INTERFERENCE

Mass interference is the major problem, for example by isobaric species that significantly overlap the mass signal of the ions of interest, especially in the central part of the mass range (for example 40-80 a.m.u.). The combination of atomic ions leads to polyatomic or molecular interferences (i.e. $^{40}Ar^{16}O$ with ^{56}Fe or $^{40}Ar^{40}Ar$ with ^{80}Se). Matrix interference may also occur with some analytes. Some samples have an impact on droplet formation or on the ionisation temperature in the plasma. These phenomena may lead to the suppression of analyte signals. Physical interference is to be circumvented by using the method of internal standardisation or by standard addition. The element used as internal standard depends on the element to be measured: ^{59}Co and ^{115}In, for example, can be used as internal standards.

The prime characteristic of an ICP-MS instrument is its resolution, i.e. the efficiency of separation of 2 close masses. Quadrupole instruments are, from this point of view, inferior to magnetic-sector spectrometers.

PROCEDURE

SAMPLE PREPARATIONS AND SAMPLE INTRODUCTION

The sample preparation usually involves a step of digestion of the matrix by a suitable method, for example in a microwave oven. Furthermore, it is important to ensure that the analyte concentration falls within the working range of the instrument through dilution or preconcentration, and that the sample-containing solution can be nebulised in a reproducible manner.

Several sample-introduction systems tolerate high acid concentrations, but the use of sulphuric and phosphoric acids can contribute to background emission. Therefore, nitric and hydrochloric acids are preferable. The availability of hydrofluoric acid-resistant (for example perfluoroalkoxy polymer) sample-introduction systems and torches also allows the use of hydrofluoric acid. In selecting a sample-introduction method, the requirements for sensitivity, stability, speed, sample size, corrosion resistance and resistance to clogging have to be considered. The use of a cross-flow nebuliser combined with a spray chamber and torch is suitable for most requirements. The peristaltic pumps usually deliver the standard and sample solutions at a rate of 20-1000 µl/min.

In the case of organic solvents being used, the introduction of oxygen must be considered to avoid organic layers.

CHOICE OF OPERATING CONDITIONS

The standard operating conditions prescribed by the manufacturer are to be followed. Usually, different sets of operating conditions are used for aqueous solutions and for organic solvents. Suitable operating parameters are to be properly chosen:

- selection of cones (material of sampler and skimmer);
- support-gas flow rates (outer, intermediate and inner tubes of the torch);
- RF power;
- pump speed;
- selection of one or more isotopes of the element to be measured (mass).

ISOTOPE SELECTION

Isotope selection is made using several criteria. The most abundant isotope for a given element is selected to obtain maximum sensitivity. Furthermore, an isotope with the least interference from other species in the sample matrix and from the support gas should be selected. Information about isobaric interferences and interferences from polyatomic ions

of various types, for example hydrides, oxides, chlorides, etc., is usually available in the software of ICP-MS instrument manufacturers.

CONTROL OF INSTRUMENT PERFORMANCE

System suitability

- Tuning of the instrument allows to monitor and adjust the measurement before running samples. ICP-MS mass accuracy is checked with a tuning solution containing several isotopes covering the whole range of masses, for example ^{9}Be, ^{59}Co, ^{89}Y, ^{115}In, ^{140}Ce and ^{209}Bi.
- Sensitivity and short- and long-term stability are recorded. The instrument parameters (plasma condition, ion lenses and quadrupole parameter) are to be optimised to obtain the highest possible number of counts.
- Tuning for resolution and mass axis is to be done with a solution of Li, Y and Tl to ensure an acceptable response over a wide range of masses.
- Evaluation of the efficiency of the plasma to decompose oxides has to be performed in order to minimise these interferences. The ratio Ce/CeO and/or Ba/BaO is a good indicator, and a level less than about 3 per cent is required.
- Reduction of the formation of double-charged ions is made with Ba and Ce. The ratio of the signal for double-charged ions to the assigned element should be less than 2 per cent.
- Long-term stability is checked by running a standard first and at the end of the sample sequence, controlling whether salt deposits on the cones have reduced the signal throughout the run.

VALIDATION OF THE METHOD

Satisfactory performance of methods prescribed in monographs is verified at suitable time intervals.

LINEARITY

Prepare and analyse not fewer than 4 reference solutions over the calibration range plus a blank. Perform not fewer than 5 replicates.

The calibration curve is calculated by least-square regression from all measured data of the calibration test. The regression curve, the means, the measured data and the confidence interval of the calibration curve are plotted. The operating method is valid when:

- the correlation coefficient is at least 0.99;
- the residuals of each calibration level are randomly distributed around the calibration curve.

Calculate the mean and relative standard deviation for the lowest and for the highest calibration level.

When the ratio of the estimated standard deviations of the lowest and the highest calibration level is less than 0.5 or greater than 2.0, a more precise estimation of the calibration curve may be obtained using weighted linear regression. Both linear and quadratic weighting functions are applied to the data to find the most appropriate weighting function to be employed.

If the means compared to the calibration curve show a deviation from linearity, two-dimensional linear regression is used.

ACCURACY

Verify the accuracy preferably by using a certified reference material (CRM). Where this is not possible, perform a test for recovery.

Recovery. For assay determinations a recovery of 90 per cent to 110 per cent is to be obtained. The test is not valid if recovery, for example for trace-element determination, is outside the range 80 per cent to 120 per cent of the theoretical value. Recovery may be determined on a suitable reference solution (matrix solution) spiked with a known quantity of analyte (concentration range that is relevant to the samples to be determined).

REPEATABILITY

The repeatability is not greater than 3 per cent for an assay and not greater than 5 per cent for an impurity test.

LIMIT OF QUANTIFICATION

Verify that the limit of quantification (for example, determined using the 10 σ approach) is below the value to be measured.

2.3.1. IDENTIFICATION REACTIONS OF IONS AND FUNCTIONAL GROUPS

ACETATES

a) Heat the substance to be examined with an equal quantity of *oxalic acid R*. Acid vapours with the characteristic odour of acetic acid are liberated, showing an acid reaction (*2.2.4*).

b) Dissolve about 30 mg of the substance to be examined in 3 ml of *water R* or use 3 ml of the prescribed solution. Add successively 0.25 ml of *lanthanum nitrate solution R*, 0.1 ml of *0.05 M iodine* and 0.05 ml of *dilute ammonia R2*. Heat carefully to boiling. Within a few minutes a blue precipitate is formed or a dark blue colour develops.

ACETYL

In a test-tube about 180 mm long and 18 mm in external diameter, place about 15 mg of the substance to be examined, or the prescribed quantity, and 0.15 ml of *phosphoric acid R*. Close the tube with a stopper through which passes a small test-tube about 100 mm long and 10 mm in external diameter containing *water R* to act as a condenser. On the outside of the smaller tube, hang a drop of *lanthanum nitrate solution R*. Except for substances hydrolysable only with difficulty, place the apparatus in a water-bath for 5 min, then take out the smaller tube. Remove the drop and mix it with 0.05 ml of *0.01 M iodine* on a tile. Add at the edge 0.05 ml of *dilute ammonia R2*. After 1 min to 2 min, a blue colour develops at the junction of the two drops; the colour intensifies and persists for a short time.

For *substances hydrolysable only with difficulty* heat the mixture slowly to boiling over an open flame and then proceed as prescribed above.

ALKALOIDS

Dissolve a few milligrams of the substance to be examined, or the prescribed quantity, in 5 ml of *water R*, add *dilute hydrochloric acid R* until an acid reaction occurs (*2.2.4*), then 1 ml of *potassium iodobismuthate solution R*. An orange or orange-red precipitate is formed immediately.

ALUMINIUM

Dissolve about 15 mg of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add about 0.5 ml of *dilute hydrochloric acid R* and about 0.5 ml of *thioacetamide reagent R*. No precipitate is formed. Add dropwise *dilute sodium hydroxide solution R*. A gelatinous white precipitate is formed which dissolves on further addition of *dilute sodium hydroxide solution R*. Gradually add *ammonium chloride solution R*. The gelatinous white precipitate is re-formed.

AMINES, PRIMARY AROMATIC

Acidify the prescribed solution with *dilute hydrochloric acid R* and add 0.2 ml of *sodium nitrite solution R*. After 1 min to 2 min, add 1 ml of *β-naphthol solution R*. An intense orange or red colour and usually a precipitate of the same colour are produced.

AMMONIUM SALTS

To the prescribed solution add 0.2 g of *magnesium oxide R*. Pass a current of air through the mixture and direct the gas that escapes just beneath the surface of a mixture of 1 ml of *0.1 M hydrochloric acid* and 0.05 ml of *methyl red solution R*. The colour of the indicator changes to yellow. On addition of 1 ml of a freshly prepared 100 g/l solution of *sodium cobaltinitrite R* a yellow precipitate is formed.

AMMONIUM SALTS AND SALTS OF VOLATILE BASES

Dissolve about 20 mg of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 2 ml of *dilute sodium hydroxide solution R*. On heating, the solution gives off vapour that can be identified by its odour and by its alkaline reaction (*2.2.4*).

ANTIMONY

Dissolve with gentle heating about 10 mg of the substance to be examined in a solution of 0.5 g of *sodium potassium tartrate R* in 10 ml of *water R* and allow to cool: to 2 ml of this solution, or to 2 ml of the prescribed solution, add *sodium sulphide solution R* dropwise; an orange-red precipitate is formed which dissolves on addition of *dilute sodium hydroxide solution R*.

ARSENIC

Heat 5 ml of the prescribed solution on a water-bath with an equal volume of *hypophosphorous reagent R*. A brown precipitate is formed.

BARBITURATES, NON-NITROGEN SUBSTITUTED

Dissolve about 5 mg of the substance to be examined in 3 ml of *methanol R*, add 0.1 ml of a solution containing 100 g/l of *cobalt nitrate R* and 100 g/l of *calcium chloride R*. Mix and add, with shaking, 0.1 ml of *dilute sodium hydroxide solution R*. A violet-blue colour and precipitate are formed.

BENZOATES

a) To 1 ml of the prescribed solution add 0.5 ml of *ferric chloride solution R1*. A dull-yellow precipitate, soluble in *ether R*, is formed.

b) Place 0.2 g of the substance to be examined, treated if necessary as prescribed, in a test-tube. Moisten with 0.2 ml to 0.3 ml of *sulphuric acid R*. Gently warm the bottom of the tube. A white sublimate is deposited on the inner wall of the tube.

c) Dissolve 0.5 g of the substance to be examined in 10 ml of *water R* or use 10 ml of the prescribed solution. Add 0.5 ml of *hydrochloric acid R*. The precipitate obtained, after crystallisation from warm *water R* and drying *in vacuo*, has a melting point (*2.2.14*) of 120 °C to 124 °C.

BISMUTH

a) To 0.5 g of the substance to be examined add 10 ml of *dilute hydrochloric acid R* or use 10 ml of the prescribed solution. Heat to boiling for 1 min. Cool and filter if necessary. To 1 ml of the solution obtained add 20 ml of *water R*. A white or slightly yellow precipitate is formed which on addition of 0.05 ml to 0.1 ml of *sodium sulphide solution R* turns brown.

b) To about 45 mg of the substance to be examined add 10 ml of *dilute nitric acid R* or use 10 ml of the prescribed solution. Boil for 1 min. Allow to cool and filter if necessary. To 5 ml of the solution obtained add 2 ml of a 100 g/l solution of *thiourea R*. A yellowish-orange colour or an orange precipitate is formed. Add 4 ml of a 25 g/l solution of *sodium fluoride R*. The solution is not decolorised within 30 min.

BROMIDES

a) Dissolve in 2 ml of *water R* a quantity of the substance to be examined equivalent to about 3 mg of bromide (Br^-) or use 2 ml of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 ml of *silver nitrate solution R1*.

Shake and allow to stand. A curdled, pale yellow precipitate is formed. Centrifuge and wash the precipitate with three quantities, each of 1 ml, of *water R*. Carry out this operation rapidly in subdued light disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate obtained in 2 ml of *water R* and add 1.5 ml of *ammonia R*. The precipitate dissolves with difficulty.

b) Introduce into a small test-tube a quantity of the substance to be examined equivalent to about 5 mg of bromide (Br^-) or the prescribed quantity. Add 0.25 ml of *water R*, about 75 mg of *lead dioxide R*, 0.25 ml of *acetic acid R* and shake gently. Dry the inside of the upper part of the test-tube with a piece of filter paper and allow to stand for 5 min. Prepare a strip of suitable filter paper of appropriate size. Impregnate it by capillarity, by dipping the tip in a drop of *decolorised fuchsin solution R* and introduce the impregnated part immediately into the tube. Starting from the tip, a violet colour appears within 10 s that is clearly distinguishable from the red colour of fuchsin, which may be visible on a small area at the top of the impregnated part of the paper strip.

CALCIUM

a) To 0.2 ml of a neutral solution containing a quantity of the substance to be examined equivalent to about 0.2 mg of calcium (Ca^{2+}) per millilitre or to 0.2 ml of the prescribed solution add 0.5 ml of a 2 g/l solution of *glyoxal-hydroxyanil R* in *ethanol (96 per cent) R*, 0.2 ml of *dilute sodium hydroxide solution R* and 0.2 ml of *sodium carbonate solution R*. Shake with 1 ml to 2 ml of *chloroform R* and add 1 ml to 2 ml of *water R*. The chloroform layer is coloured red.

b) Dissolve about 20 mg of the substance to be examined or the prescribed quantity in 5 ml of *acetic acid R*. Add 0.5 ml of *potassium ferrocyanide solution R*. The solution remains clear. Add about 50 mg of *ammonium chloride R*. A white, crystalline precipitate is formed.

CARBONATES AND BICARBONATES

Introduce into a test-tube 0.1 g of the substance to be examined and suspend in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 3 ml of *dilute acetic acid R*. Close the tube immediately using a stopper fitted with a glass tube bent twice at right angles. The solution or the suspension becomes effervescent and gives off a colourless and odourless gas. Heat gently and collect the gas in 5 ml of *barium hydroxide solution R*. A white precipitate is formed that dissolves on addition of an excess of *hydrochloric acid R1*.

CHLORIDES

a) Dissolve in 2 ml of *water R* a quantity of the substance to be examined equivalent to about 2 mg of chloride (Cl^-) or use 2 ml of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 ml of *silver nitrate solution R1*. Shake and allow to stand. A curdled, white precipitate is formed. Centrifuge and wash the precipitate with three quantities, each of 1 ml, of *water R*. Carry out this operation rapidly in subdued light, disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate in 2 ml of *water R* and add 1.5 ml of *ammonia R*. The precipitate dissolves easily with the possible exception of a few large particles which dissolve slowly.

b) Introduce into a test-tube a quantity of the substance to be examined equivalent to about 15 mg of chloride (Cl^-) or the prescribed quantity. Add 0.2 g of *potassium dichromate R* and 1 ml of *sulphuric acid R*. Place a filter-paper strip impregnated with 0.1 ml of *diphenylcarbazide solution R* over the opening of the test-tube. The paper turns violet-red. The impregnated paper must not come into contact with the potassium dichromate.

CITRATES

Dissolve in 5 ml of *water R* a quantity of the substance to be examined equivalent to about 50 mg of citric acid or use 5 ml of the prescribed solution. Add 0.5 ml of *sulphuric acid R* and 1 ml of *potassium permanganate solution R*. Warm until the colour of the permanganate is discharged. Add 0.5 ml of a 100 g/l solution of *sodium nitroprusside R* in *dilute sulphuric acid R* and 4 g of *sulphamic acid R*. Make alkaline with *concentrated ammonia R*, added dropwise until all the sulphamic acid has dissolved. Addition of an excess of *concentrated ammonia R* produces a violet colour, turning to violet-blue.

ESTERS

To about 30 mg of the substance to be examined or the prescribed quantity add 0.5 ml of a 70 g/l solution of *hydroxylamine hydrochloride R* in *methanol R* and 0.5 ml of a 100 g/l solution of *potassium hydroxide R* in *ethanol (96 per cent) R*. Heat to boiling, cool, acidify with *dilute hydrochloric acid R* and add 0.2 ml of *ferric chloride solution R1* diluted ten times. A bluish-red or red colour is produced.

IODIDES

a) Dissolve a quantity of the substance to be examined equivalent to about 4 mg of iodide (I^-) in 2 ml of *water R* or use 2 ml of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 ml of *silver nitrate solution R1*. Shake and allow to stand. A curdled, pale-yellow precipitate is formed. Centrifuge and wash with three quantities, each of 1 ml, of *water R*. Carry out this operation rapidly in subdued light disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate in 2 ml of *water R* and add 1.5 ml of *ammonia R*. The precipitate does not dissolve.

b) To 0.2 ml of a solution of the substance to be examined containing about 5 mg of iodide (I^-) per millilitre, or to 0.2 ml of the prescribed solution, add 0.5 ml of *dilute sulphuric acid R*, 0.1 ml of *potassium dichromate solution R*, 2 ml of *water R* and 2 ml of *chloroform R*. Shake for a few seconds and allow to stand. The chloroform layer is coloured violet or violet-red.

IRON

a) Dissolve a quantity of the substance to be examined equivalent to about 10 mg of iron (Fe^{2+}) in 1 ml of *water R* or use 1 ml of the prescribed solution. Add 1 ml of *potassium ferricyanide solution R*. A blue precipitate is formed that does not dissolve on addition of 5 ml of *dilute hydrochloric acid R*.

b) Dissolve a quantity of the substance to be examined equivalent to about 1 mg of iron (Fe^{3+}) in 30 ml of *water R*. To 3 ml of this solution or to 3 ml of the prescribed solution, add 1 ml of *dilute hydrochloric acid R* and 1 ml of *potassium thiocyanate solution R*. The solution is coloured red. Take two portions, each of 1 ml, of the mixture. To one portion add 5 ml of *isoamyl alcohol R* or 5 ml of *ether R*. Shake and allow to stand. The organic layer is coloured pink. To the other portion add 2 ml of *mercuric chloride solution R*. The red colour disappears.

c) Dissolve a quantity of the substance to be examined equivalent to not less than 1 mg of iron (Fe^{3+}) in 1 ml of *water R* or use 1 ml of the prescribed solution. Add 1 ml

of *potassium ferrocyanide solution R*. A blue precipitate is formed that does not dissolve on addition of 5 ml of *dilute hydrochloric acid R*.

LACTATES

Dissolve a quantity of the substance to be examined equivalent to about 5 mg of lactic acid in 5 ml of *water R* or use 5 ml of the prescribed solution. Add 1 ml of *bromine water R* and 0.5 ml of *dilute sulphuric acid R*. Heat on a water-bath until the colour is discharged, stirring occasionally with a glass rod. Add 4 g of *ammonium sulphate R* and mix. Add dropwise and without mixing 0.2 ml of a 100 g/l solution of *sodium nitroprusside R* in *dilute sulphuric acid R*. Still without mixing add 1 ml of *concentrated ammonia R*. Allow to stand for 30 min. A dark green ring appears at the junction of the two liquids.

LEAD

a) Dissolve 0.1 g of the substance to be examined in 1 ml of *acetic acid R* or use 1 ml of the prescribed solution. Add 2 ml of *potassium chromate solution R*. A yellow precipitate is formed that dissolves on addition of 2 ml of *strong sodium hydroxide solution R*.

b) Dissolve 50 mg of the substance to be examined in 1 ml of *acetic acid R* or use 1 ml of the prescribed solution. Add 10 ml of *water R* and 0.2 ml of *potassium iodide solution R*. A yellow precipitate is formed. Heat to boiling for 1 min to 2 min. The precipitate dissolves. Allow to cool. The precipitate is re-formed as glistening, yellow plates.

MAGNESIUM

Dissolve about 15 mg of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 1 ml of *dilute ammonia R1*. A white precipitate is formed that dissolves on addition of 1 ml of *ammonium chloride solution R*. Add 1 ml of *disodium hydrogen phosphate solution R*. A white crystalline precipitate is formed.

MERCURY

a) Place about 0.1 ml of a solution of the substance to be examined on well-scraped copper foil. A dark-grey stain that becomes shiny on rubbing is formed. Dry the foil and heat in a test-tube. The spot disappears.

b) To the prescribed solution add *dilute sodium hydroxide solution R* until strongly alkaline (*2.2.4*). A dense yellow precipitate is formed (mercuric salts).

NITRATES

To a mixture of 0.1 ml of *nitrobenzene R* and 0.2 ml of *sulphuric acid R*, add a quantity of the powdered substance equivalent to about 1 mg of nitrate (NO_3^-) or the prescribed quantity. Allow to stand for 5 min. Cool in iced water and add slowly and with mixing 5 ml of *water R*, then 5 ml of *strong sodium hydroxide solution R*. Add 5 ml of *acetone R*. Shake and allow to stand. The upper layer is coloured deep violet.

PHOSPHATES (ORTHOPHOSPHATES)

a) To 5 ml of the prescribed solution, neutralised if necessary, add 5 ml of *silver nitrate solution R1*. A yellow precipitate is formed whose colour is not changed by boiling and which dissolves on addition of *ammonia R*.

b) Mix 1 ml of the prescribed solution with 2 ml of *molybdovanadic reagent R*. A yellow colour develops.

POTASSIUM

a) Dissolve 0.1 g of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 1 ml of *sodium carbonate solution R* and heat. No precipitate is formed. Add to the hot solution 0.05 ml of *sodium sulphide solution R*. No precipitate is formed. Cool in iced water and add 2 ml of a 150 g/l solution of *tartaric acid R*. Allow to stand. A white crystalline precipitate is formed.

b) Dissolve about 40 mg of the substance to be examined in 1 ml of *water R* or use 1 ml of the prescribed solution. Add 1 ml of *dilute acetic acid R* and 1 ml of a freshly prepared 100 g/l solution of *sodium cobaltinitrite R*. A yellow or orange-yellow precipitate is formed immediately.

SALICYLATES

a) To 1 ml of the prescribed solution add 0.5 ml of *ferric chloride solution R1*. A violet colour is produced that persists after the addition of 0.1 ml of *acetic acid R*.

b) Dissolve 0.5 g of the substance to be examined in 10 ml of *water R* or use 10 ml of the prescribed solution. Add 0.5 ml of *hydrochloric acid R*. The precipitate obtained, after recrystallisation from hot *water R* and drying *in vacuo*, has a melting point (*2.2.14*) of 156 °C to 161 °C.

SILICATES

Mix the prescribed quantity of the substance to be examined in a lead or platinum crucible by means of a copper wire with about 10 mg of *sodium fluoride R* and a few drops of *sulphuric acid R* to give a thin slurry. Cover the crucible with a thin, transparent plate of plastic under which a drop of *water R* is suspended and warm gently. Within a short time a white ring is rapidly formed around the drop of water.

SILVER

Dissolve about 10 mg of the substance to be examined in 10 ml of *water R* or use 10 ml of the prescribed solution. Add 0.3 ml of *hydrochloric acid R1*. A curdled, white precipitate is formed that dissolves on addition of 3 ml of *dilute ammonia R1*.

SODIUM

a) Dissolve 0.1 g of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 2 ml of a 150 g/l solution of *potassium carbonate R* and heat to boiling. No precipitate is formed. Add 4 ml of *potassium pyroantimonate solution R* and heat to boiling. Allow to cool in iced water and if necessary rub the inside of the test-tube with a glass rod. A dense white precipitate is formed.

b) Dissolve a quantity of the substance to be examined equivalent to about 2 mg of sodium (Na^+) in 0.5 ml of *water R* or use 0.5 ml of the prescribed solution. Add 1.5 ml of *methoxyphenylacetic reagent R* and cool in ice-water for 30 min. A voluminous, white, crystalline precipitate is formed. Place in water at 20 °C and stir for 5 min. The precipitate does not disappear. Add 1 ml of *dilute ammonia R1*. The precipitate dissolves completely. Add 1 ml of *ammonium carbonate solution R*. No precipitate is formed.

SULPHATES

a) Dissolve about 45 mg of the substance to be examined in 5 ml of *water R* or use 5 ml of the prescribed solution. Add 1 ml of *dilute hydrochloric acid R* and 1 ml of *barium chloride solution R1*. A white precipitate is formed.

b) To the suspension obtained during reaction (a), add 0.1 ml of *0.05 M iodine*. The suspension remains yellow (distinction from sulphites and dithionites), but is decolorised by adding dropwise *stannous chloride solution R* (distinction from iodates). Boil the mixture. No coloured precipitate is formed (distinction from selenates and tungstates).

TARTRATES

a) Dissolve about 15 mg of the substance to be examined in 5 ml of *water R* or use 5 ml of the prescribed solution. Add 0.05 ml of a 10 g/l solution of *ferrous sulphate R* and 0.05 ml of *dilute hydrogen peroxide solution R*. A transient yellow colour is produced. After the colour has disappeared add *dilute sodium hydroxide solution R* dropwise. A violet or purple colour is produced.

b) To 0.1 ml of a solution of the substance to be examined containing the equivalent of about 15 mg of tartaric acid per millilitre or to 0.1 ml of the prescribed solution add 0.1 ml of a 100 g/l solution of *potassium bromide R*, 0.1 ml of a 20 g/l solution of *resorcinol R* and 3 ml of *sulphuric acid R*. Heat on a water-bath for 5 min to 10 min. A dark-blue colour develops. Allow to cool and pour the solution into *water R*. The colour changes to red.

XANTHINES

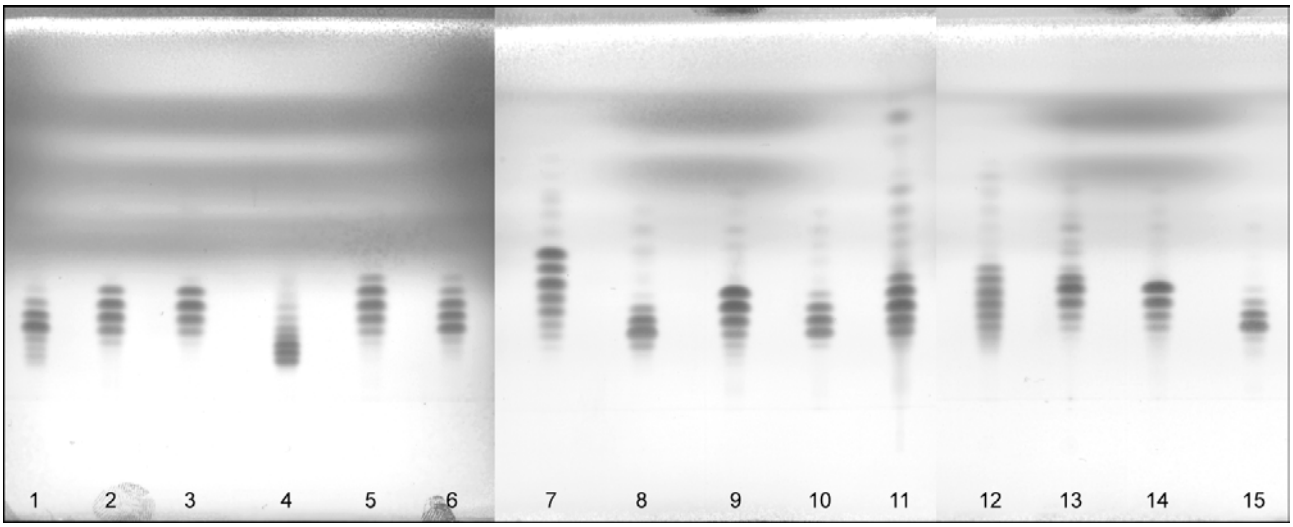
To a few milligrams of the substance to be examined or the prescribed quantity add 0.1 ml of *strong hydrogen peroxide solution R* and 0.3 ml of *dilute hydrochloric acid R*. Heat to dryness on a water-bath until a yellowish-red residue is obtained. Add 0.1 ml of *dilute ammonia R2*. The colour of the residue changes to violet-red.

ZINC

Dissolve 0.1 g of the substance to be examined in 5 ml of *water R* or use 5 ml of the prescribed solution. Add 0.2 ml of *strong sodium hydroxide solution R*. A white precipitate is formed. Add a further 2 ml of *strong sodium hydroxide solution R*. The precipitate dissolves. Add 10 ml of *ammonium chloride solution R*. The solution remains clear. Add 0.1 ml of *sodium sulphide solution R*. A flocculent white precipitate is formed.

01/2008:20302

2.3.2. IDENTIFICATION OF FATTY OILS BY THIN-LAYER CHROMATOGRAPHY



Examine by thin-layer chromatography (*2.2.27*), using as the coating substance a suitable octadecylsilyl silica gel for high performance thin-layer chromatography.

Test solution. Unless otherwise prescribed, dissolve about 20 mg (1 drop) of the fatty oil in 3 ml of *methylene chloride R*.

Reference solution. Dissolve about 20 mg (1 drop) of *maize oil R* in 3 ml of *methylene chloride R*.

Apply separately to the plate 1 µl of each solution. Develop twice over a path of 0.5 cm using *ether R*. Develop twice over a path of 8 cm using a mixture of 20 volumes of *methylene chloride R*, 40 volumes of *glacial acetic acid R* and 50 volumes of *acetone R*. Allow the plate to dry in air and spray with a 100 g/l solution of *phosphomolybdic acid R* in *alcohol R*. Heat the plate at 120 °C for about 3 min and examine in daylight.

The chromatogram obtained typically shows spots comparable to those in Figure 2.3.2.-1.

1. arachis oil
2. sesame oil
3. maize oil
4. rapeseed oil
5. soya-bean oil
6. rapeseed oil (erucic acid-free)
7. linseed oil
8. olive oil
9. sunflower oil
10. almond oil
11. wheat-germ oil
12. borage oil
13. evening primrose oil

01/2008:20303

2.3.3. IDENTIFICATION OF PHENOTHIAZINES BY THIN-LAYER CHROMATOGRAPHY

Examine by thin-layer chromatography (*2.2.27*) using *kieselguhr G R* as the coating substance. Impregnate the plate by placing it in a closed tank containing the necessary quantity of the impregnation mixture composed of a solution containing 10 per cent *V/V* of *phenoxyethanol R* and 50 g/l of *macrogol 300 R* in *acetone R* so that the plate dips about 5 mm beneath the surface of the liquid. When the impregnation mixture has risen at least 17 cm from the lower edge of the plate, remove the plate and use immediately for chromatography. Carry out the chromatography in the same direction as the impregnation.

Test solution. Dissolve 20 mg of the substance to be examined in *chloroform R* and dilute to 10 ml with the same solvent.

Reference solution. Dissolve 20 mg of the corresponding chemical reference substance (CRS) in *chloroform R* and dilute to 10 ml with the same solvent.

Apply separately to the plate 2 µl of each solution and develop in the dark over a path of 15 cm using a mixture of 50 ml of *light petroleum R* and 1 ml of *diethylamine R* saturated with *phenoxyethanol R* (i.e. add about 3 ml to 4 ml of *phenoxyethanol R* to the above mixture of solvents to give a persistent cloudiness on shaking, decant, and use the supernatant liquid, even if it is cloudy). After development place the plate under ultraviolet light at 365 nm and examine after a few minutes. The spot in the chromatogram obtained with the test solution is similar in position, fluorescence and size to the spot in the chromatogram obtained with the reference solution. Spray with a 10 per cent *V/V* solution of *sulphuric acid R* in *alcohol R*. The spot in the chromatogram obtained with the test solution is of the same colour as that in the chromatogram obtained with the reference solution and has similar stability over a period of at least 20 min.

01/2008:20304

2.3.4. ODOUR

On a watch-glass 6 cm to 8 cm in diameter, spread in a thin layer 0.5 g to 2.0 g of the substance to be examined. After 15 min, determine the odour or verify the absence of odour.

2.4. LIMIT TESTS

01/2008:20401

2.4.1. AMMONIUM

Unless otherwise prescribed, use method A.

METHOD A

Dissolve the prescribed quantity of the substance to be examined in 14 ml of *water R* in a test-tube, make alkaline if necessary by the addition of *dilute sodium hydroxide solution R* and dilute to 15 ml with *water R*. To the solution add 0.3 ml of *alkaline potassium tetraiodomercurate solution R*. Prepare a standard by mixing 10 ml of *ammonium standard solution (1 ppm NH_4) R* with 5 ml of *water R* and 0.3 ml of *alkaline potassium tetraiodomercurate solution R*. Stopper the test-tubes.

After 5 min, any yellow colour in the test solution is not more intense than that in the standard.

METHOD B

In a 25 ml jar fitted with a cap, place the prescribed quantity of the finely powdered substance to be examined and dissolve or suspend in 1 ml of *water R*. Add 0.30 g of *heavy magnesium oxide R*. Close immediately after placing a piece of *silver manganese paper R* 5 mm square, wetted with a few drops of *water R*, under the polyethylene cap. Swirl, avoiding projections of liquid, and allow to stand at 40 °C for 30 min. If the silver manganese paper shows a grey colour, it is not more intense than that of a standard prepared at the same time and in the same manner using the prescribed volume of *ammonium standard solution (1 ppm NH_4) R*, 1 ml of *water R* and 0.30 g of *heavy magnesium oxide R*.

01/2008:20402

2.4.2. ARSENIC

METHOD A

The apparatus (see Figure 2.4.2.-1) consists of a 100 ml conical flask closed with a ground-glass stopper through which passes a glass tube about 200 mm long and of internal diameter 5 mm. The lower part of the tube is drawn to an internal diameter of 1.0 mm, and 15 mm from its tip is a lateral orifice 2 mm to 3 mm in diameter. When the tube is in position in the stopper, the lateral orifice should be at least 3 mm below the lower surface of the stopper. The upper end of the tube has a perfectly flat, ground surface at right angles to the axis of the tube. A second glass tube of the same internal diameter and 30 mm long, with a similar flat ground surface, is placed in contact with the first, and is held in position by two spiral springs. Into the lower tube insert 50 mg to 60 mg of *lead acetate cotton R*, loosely packed, or a small plug of cotton and a rolled piece of *lead acetate paper R* weighing 50 mg to 60 mg. Between the flat surfaces of the tubes place a disc or a small square of *mercuric bromide paper R* large enough to cover the orifice of the tube (15 mm × 15 mm).

In the conical flask dissolve the prescribed quantity of the substance to be examined in 25 ml of *water R*, or in the case of a solution adjust the prescribed volume to 25 ml with *water R*. Add 15 ml of *hydrochloric acid R*, 0.1 ml of *stannous chloride solution R* and 5 ml of *potassium iodide solution R*, allow to stand for 15 min and introduce 5 g of *activated zinc R*. Assemble the two parts of the apparatus immediately and immerse the flask in a bath of water at a temperature such that a uniform evolution of gas is maintained. Prepare a standard in the same manner, using 1 ml of *arsenic standard solution (1 ppm As) R*, diluted to 25 ml with *water R*.

After not less than 2 h the stain produced on the mercuric bromide paper in the test is not more intense than that in the standard.

METHOD B

Introduce the prescribed quantity of the substance to be examined into a test-tube containing 4 ml of *hydrochloric acid R* and about 5 mg of *potassium iodide R* and add 3 ml of *hypophosphorous reagent R*. Heat the mixture on a water-bath for 15 min, shaking occasionally. Prepare a standard in the same manner, using 0.5 ml of *arsenic standard solution (10 ppm As) R*.

After heating on the water-bath, any colour in the test solution is not more intense than that in the standard.

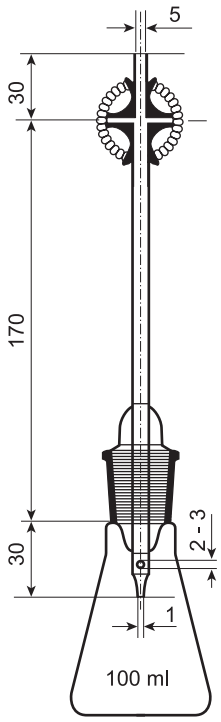

Figure 2.4.2.-1. - *Apparatus for limit test A for arsenic*
Dimensions in millimetres

01/2008:20403

2.4.3. CALCIUM

All solutions used for this test should be prepared with distilled water R.

To 0.2 ml of *alcoholic calcium standard solution (100 ppm Ca) R*, add 1 ml of *ammonium oxalate solution R*. After 1 min, add a mixture of 1 ml of *dilute acetic acid R* and 15 ml of a solution containing the prescribed quantity of the substance to be examined and shake. Prepare a standard in the same manner using a mixture of 10 ml of *aqueous calcium standard solution (10 ppm Ca) R*, 1 ml of *dilute acetic acid R* and 5 ml of *distilled water R*.

After 15 min, any opalescence in the test solution is not more intense than that in the standard.

01/2008:20404

2.4.4. CHLORIDES

To 15 ml of the prescribed solution add 1 ml of *dilute nitric acid R* and pour the mixture as a single addition into a test-tube containing 1 ml of *silver nitrate solution R2*. Prepare a standard in the same manner using 10 ml of *chloride standard solution (5 ppm Cl) R* and 5 ml of *water R*. Examine the tubes laterally against a black background.

After standing for 5 min protected from light, any opalescence in the test solution is not more intense than that in the standard.

01/2008:20405

2.4.5. FLUORIDES

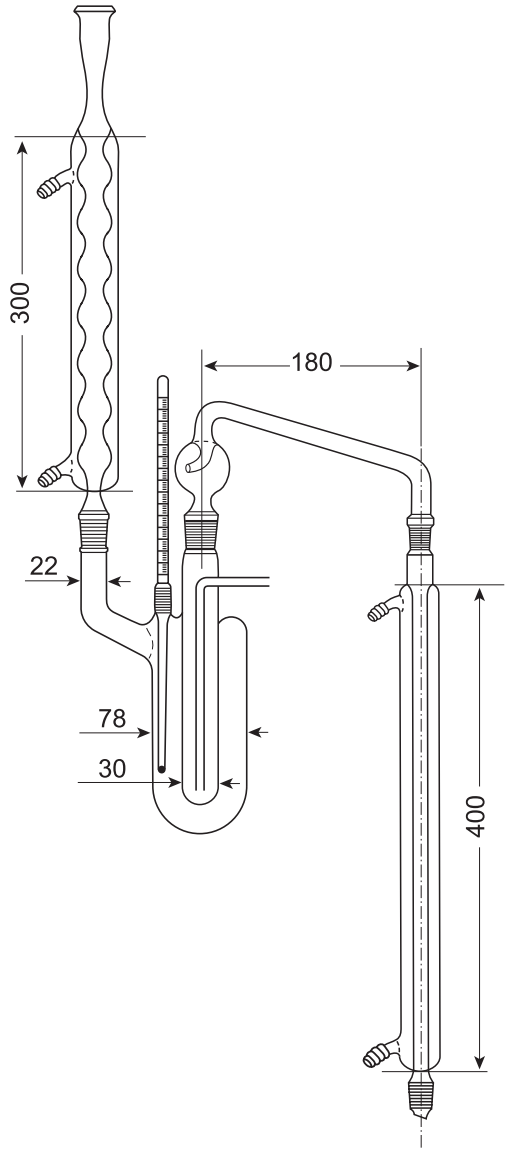

Figure 2.4.5.-1. – *Apparatus for limit test for fluorides*
Dimensions in millimetres

Introduce into the inner tube of the apparatus (see Figure 2.4.5.-1) the prescribed quantity of the substance to be examined, 0.1 g of acid-washed *sand R* and 20 ml of a mixture of equal volumes of *sulphuric acid R* and *water R*. Heat the jacket containing *tetrachloroethane R* maintained at its boiling point (146 °C). Heat the steam generator and distil, collecting the distillate in a 100 ml volumetric flask containing 0.3 ml of *0.1 M sodium hydroxide* and 0.1 ml of *phenolphthalein solution R*. Maintain a constant volume (20 ml) in the tube during distillation and ensure that the distillate remains alkaline, adding *0.1 M sodium hydroxide* if necessary. Dilute the distillate to 100 ml with *water R* (test solution). Prepare a standard in the same manner by distillation, using 5 ml of *fluoride standard solution (10 ppm F) R* instead of the substance to be examined. Into two glass-stoppered cylinders introduce 20 ml of the test solution and 20 ml of the standard and 5 ml of *aminomethylalizarindiacetic acid reagent R*.

After 20 min, any blue colour in the test solution (originally red) is not more intense than that in the standard.

01/2008:20406

2.4.6. MAGNESIUM

To 10 ml of the prescribed solution add 0.1 g of *disodium tetraborate R*. Adjust the solution, if necessary, to pH 8.8 to pH 9.2 using *dilute hydrochloric acid R* or *dilute sodium hydroxide solution R*. Shake with 2 quantities, each of 5 ml, of a 1 g/l solution of *hydroxyquinoline R* in *chloroform R*, for 1 min each time. Allow to stand. Separate and discard the organic layer. To the aqueous solution add 0.4 ml of *butylamine R* and 0.1 ml of *triethanolamine R*. Adjust the solution, if necessary, to pH 10.5 to pH 11.5. Add 4 ml of the solution of hydroxyquinoline in chloroform, shake for 1 min, allow to stand and separate. Use the lower layer for comparison. Prepare a standard in the same manner using a mixture of 1 ml of *magnesium standard solution (10 ppm Mg) R* and 9 ml of *water R*.

Any colour in the solution obtained from the substance to be examined is not more intense than that in the standard.

01/2008:20407

2.4.7. MAGNESIUM AND ALKALINE-EARTH METALS

To 200 ml of *water R* add 0.1 g of *hydroxylamine hydrochloride R*, 10 ml of *ammonium chloride buffer solution pH 10.0 R*, 1 ml of *0.1 M zinc sulphate* and about 15 mg of *mordant black 11 triturate R*. Heat to about 40 °C. Titrate with *0.01 M sodium edetate* until the violet colour changes to full blue. To the solution add the prescribed quantity of the substance to be examined dissolved in 100 ml of *water R* or use the prescribed solution. If the colour of the solution changes to violet, titrate with *0.01 M sodium edetate* until the full blue colour is again obtained.

The volume of *0.01 M sodium edetate* used in the second titration does not exceed the prescribed quantity.

01/2008:20408
corrected 6.0

2.4.8. HEAVY METALS

The methods described below require the use of *thioacetamide reagent R*. As an alternative, *sodium sulphide solution R1* (0.1 ml) is usually suitable. Since tests prescribed in monographs have been developed using *thioacetamide reagent R*, if *sodium sulphide solution R1* is used instead, it is necessary to include also for methods A and B a monitor solution, prepared from the quantity of the substance to be examined prescribed for the test, to

which has been added the volume of lead standard solution prescribed for preparation of the reference solution. The test is invalid if the monitor solution is not at least as intense as the reference solution.

METHOD A

Test solution. 12 ml of the prescribed aqueous solution of the substance to be examined.

Reference solution (standard). A mixture of 10 ml of *lead standard solution (1 ppm Pb) R* or *lead standard solution (2 ppm Pb) R*, as prescribed, and 2 ml of the prescribed aqueous solution of the substance to be examined.

Blank solution. A mixture of 10 ml of *water R* and 2 ml of the prescribed aqueous solution of the substance to be examined.

To each solution, add 2 ml of *buffer solution pH 3.5 R*. Mix and add to 1.2 ml of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min. The test is invalid if the reference solution does not show a slight brown colour compared to the blank solution. The substance to be examined complies with the test if any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8.-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD B

Test solution. 12 ml of the prescribed solution of the substance to be examined prepared using an organic solvent containing a minimum percentage of water (for example, dioxan containing 15 per cent of water or acetone containing 15 per cent of water).

Reference solution (standard). A mixture of 10 ml of lead standard solution (1 or 2 ppm Pb), as prescribed, and 2 ml of the prescribed solution of the substance to be examined in an organic solvent. Prepare the lead standard solution (1 or 2 ppm Pb) by dilution of *lead standard solution (100 ppm Pb) R* with the solvent used for the substance to be examined.

Blank solution. A mixture of 10 ml of the solvent used for the substance to be examined and 2 ml of the prescribed solution of the substance to be examined in an organic solvent.

To each solution, add 2 ml of *buffer solution pH 3.5 R*. Mix and add to 1.2 ml of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min. The test is invalid if the reference solution does not show a slight brown colour compared to the blank solution. The substance to be examined complies with the test if any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8.-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD C

Test solution. Place the prescribed quantity (not more than 2 g) of the substance to be examined in a silica crucible with 4 ml of a 250 g/l solution of *magnesium sulphate R* in *dilute sulphuric acid R*. Mix using a fine glass rod. Heat cautiously. If the mixture is liquid, evaporate gently to dryness on a water-bath. Progressively heat to ignition and continue heating until an almost white or at most greyish residue is obtained. Carry out the ignition at a temperature not exceeding 800 °C. Allow to cool. Moisten the residue with a few drops of *dilute sulphuric acid R*. Evaporate, ignite again and allow to cool. The total period of ignition must not exceed 2 h. Take up the residue in 2 quantities, each of 5 ml, of *dilute hydrochloric acid R*. Add 0.1 ml of *phenolphthalein solution R*, then *concentrated ammonia R* until a pink colour is obtained. Cool, add *glacial acetic acid R* until the solution is decolorised and add 0.5 ml in excess. Filter if necessary and wash the filter. Dilute to 20 ml with *water R*.

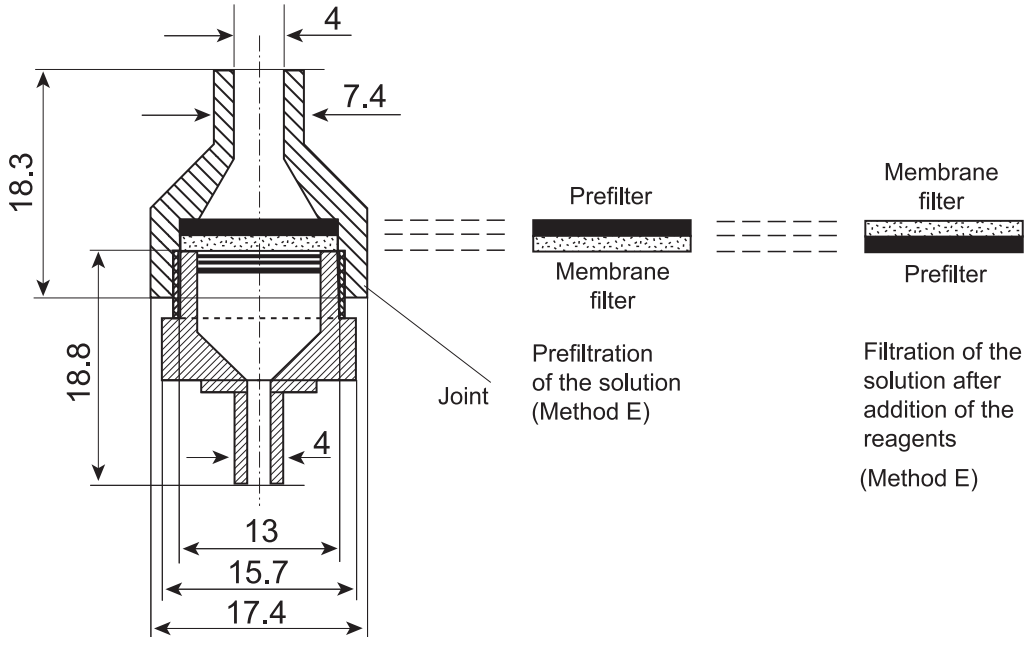

Figure 2.4.8.-1. – *Apparatus for the test for heavy metals*
Dimensions in millimetres

Reference solution (standard). Prepare as described for the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined. To 10 ml of the solution obtained add 2 ml of the test solution.

Monitor solution. Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for preparation of the reference solution. To 10 ml of the solution obtained add 2 ml of the test solution.

Blank solution. A mixture of 10 ml of *water R* and 2 ml of the test solution.

To 12 ml of each solution, add 2 ml of *buffer solution pH 3.5 R*. Mix and add to 1.2 ml of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min. The test is invalid if the reference solution does not show a slight brown colour compared to the blank solution or if the monitor solution is not at least as intense as the reference solution. The substance to be examined complies with the test if any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8.-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD D

Test solution. In a silica crucible, mix thoroughly the prescribed quantity of the substance to be examined with 0.5 g of *magnesium oxide R1*. Ignite to dull redness until a homogeneous white or greyish-white mass is obtained. If after 30 min of ignition the mixture remains coloured, allow to cool, mix using a fine glass rod and repeat the ignition. If necessary repeat the operation. Heat at 800 °C for about 1 h. Take up the residue in 2 quantities, each of 5 ml, of a mixture of equal volumes of *hydrochloric acid R1* and *water R*. Add 0.1 ml of *phenolphthalein solution R* and then *concentrated ammonia R* until a pink colour is obtained. Cool, add *glacial acetic acid R* until the solution is decolorised and add 0.5 ml in excess. Filter if necessary and wash the filter. Dilute to 20 ml with *water R*.

Reference solution (standard). Prepare as described for the test solution using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined and drying in an oven at 100-105 °C. To 10 ml of the solution obtained add 2 ml of the test solution.

Monitor solution. Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for preparation of the reference solution and drying in an oven at 100-105 °C. To 10 ml of the solution obtained add 2 ml of the test solution.

Blank solution. A mixture of 10 ml of *water R* and 2 ml of the test solution.

To 12 ml of each solution, add 2 ml of *buffer solution pH 3.5 R*. Mix and add to 1.2 ml of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min. The test is invalid if the reference solution does not show a slight brown colour compared to the blank solution or if the monitor solution is not at least as intense as the reference solution. The substance to be examined complies with the test if any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8.-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD E

Test solution. Dissolve the prescribed quantity of the substance to be examined in 30 ml of *water R* or the prescribed volume.

Reference solution (standard). Unless otherwise prescribed, dilute the prescribed volume of *lead standard solution (1 ppm Pb) R* to the same volume as the test solution.

Prepare the filtration apparatus by adapting the barrel of a 50 ml syringe without its piston to a support containing, on the plate, a membrane filter (pore size 3 µm) and above it a prefilter (Figure 2.4.8.-1).

Transfer the test solution into the syringe barrel, put the piston in place and then apply an even pressure on it until the whole of the liquid has been filtered. In opening the support and removing the prefilter, check that the membrane filter remains uncontaminated with impurities. If this is not the case replace it with another membrane filter and repeat the operation under the same conditions.

To the prefiltrate or to the prescribed volume of the prefiltrate add 2 ml of *buffer solution pH 3.5 R*. Mix and add to 1.2 ml of *thioacetamide reagent R*. Mix immediately and allow to stand for 10 min and again filter as described above, but inverting the order of the filters, the liquid passing first through the membrane filter before passing through the prefilter (Figure 2.4.8.-1). The filtration must be carried out slowly and uniformly by applying moderate and constant pressure to the piston of the syringe. After complete filtration, open the support, remove the membrane filter, and dry using filter paper.

In parallel, treat the reference solution in the same manner as the test solution.

The colour of the spot obtained with the test solution is not more intense than that obtained with the reference solution.

METHOD F

Test solution. Place the prescribed quantity or volume of the substance to be examined in a clean, dry, 100 ml long-necked combustion flask (a 300 ml flask may be used if the reaction foams excessively). Clamp the flask at an angle of 45°. If the substance to be examined is a solid, add a sufficient volume of a mixture of 8 ml of *sulphuric acid R* and 10 ml of *nitric acid R* to moisten the substance thoroughly; if the substance to be examined is a liquid, add a few millilitres of a mixture of 8 ml of *sulphuric acid R* and 10 ml of *nitric acid R*. Warm gently until the reaction commences, allow the reaction to subside and add additional portions of the same acid mixture, heating after each addition, until a total of 18 ml of the acid mixture has been added. Increase the amount of heat and boil gently until the solution darkens. Cool, add 2 ml of *nitric acid R* and heat again until the solution darkens. Continue the heating, followed by the addition of *nitric acid R* until no further darkening occurs, then heat strongly until dense, white fumes are produced. Cool, cautiously add 5 ml of *water R*, boil gently until dense, white fumes are produced and continue heating to reduce to 2-3 ml. Cool, cautiously add 5 ml of *water R* and examine the colour of the solution. If the colour is yellow, cautiously add 1 ml of *strong hydrogen peroxide solution R* and again evaporate until dense, white fumes are produced and reduce to a volume of 2-3 ml. If the solution is still yellow in colour, repeat the addition of 5 ml of *water R* and 1 ml of

strong hydrogen peroxide solution R until the solution is colourless. Cool, dilute cautiously with *water R* and rinse into a 50 ml colour comparison tube, ensuring that the total volume does not exceed 25 ml. Adjust the solution to pH 3.0-4.0, using short range pH indicator paper as external indicator, with *concentrated ammonia R1* (*dilute ammonia R1* may be used, if desired, as the specified range is approached), dilute with *water R* to 40 ml and mix. Add 2 ml of *buffer solution pH 3.5 R*. Mix and add to 1.2 ml of *thioacetamide reagent R*. Mix immediately. Dilute to 50 ml with *water R* and mix.

Reference solution (standard). Prepare at the same time and in the same manner as the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R*.

Monitor solution. Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for the preparation of the reference solution.

Blank solution. Prepare as described for the test solution, omitting the substance to be examined.

Examine the solutions vertically against a white background. After 2 min, any brown colour in the test solution is not more intense than that in the reference solution.

The test is invalid if the reference solution does not show a brown colour compared to the blank solution or if the monitor solution is not at least as intense as the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD G

CAUTION: when using high-pressure digestion vessels the safety precautions and operating instructions given by the manufacturer must be followed. The digestion cycles have to be elaborated depending on the type of microwave oven to be used (for example, energy-controlled microwave ovens, temperature-controlled microwave ovens or high-pressure ovens). The cycle must be conform to the manufacturer's instructions. The digestion cycle is suitable if a clear solution is obtained.

Test solution. Place the prescribed amount of the substance to be examined (not more than 0.5 g) in a suitable, clean beaker. Add successively 2.7 ml of *sulphuric acid R*, 3.3 ml of *nitric acid R* and 2.0 ml of *strong hydrogen peroxide solution R* using a magnetic stirrer. Allow the substance to react with a reagent before adding the next one. Transfer the mixture to a dry high-pressure-resistant digestion vessel (fluoropolymer or quartz glass).

Reference solution (standard). Prepare as described for the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined.

Monitor solution. Prepare as prescribed for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for the preparation of the reference solution.

Blank solution. Prepare as described for the test solution, omitting the substance to be examined.

Close the vessels and place in a laboratory microwave oven. Digest using a sequence of 2 separate suitable programmes. Design the programmes in several steps in order to control the reaction, monitoring pressure, temperature or energy depending on the type of microwave oven available. After the first programme allow the digestion vessels to cool before opening. Add to each vessel 2.0 ml of *strong hydrogen peroxide solution R* and digest using the second programme. After the second programme allow the digestion vessels to cool before opening. If necessary to obtain a clear solution, repeat the addition of *strong hydrogen peroxide solution R* and the second digestion programme.

Cool, dilute cautiously with *water R* and rinse into a flask, ensuring that the total volume does not exceed 25 ml.

Using short-range pH indicator paper as external indicator, adjust the solutions to pH 3.0-4.0 with *concentrated ammonia R1* (*dilute ammonia R1* may be used as the specified range is approached). To avoid heating of the solutions use an ice-bath and a magnetic stirrer. Dilute to 40 ml with *water R* and mix. Add 2 ml of *buffer solution pH 3.5 R*. Mix and add to 1.2 ml of *thioacetamide reagent R*. Mix immediately. Dilute to 50 ml with *water R*, mix and allow to stand for 2 min.

Filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8.-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

Examine the spots on the filters. The brown colour from the spot of the test solution is not more intense than that from the reference solution.

The test is invalid if the reference solution spot does not show a brown colour compared to the blank spot, or if the spot from the monitor solution is not at least as intense as the spot from the reference solution.

01/2008:20409

2.4.9. IRON

Dissolve the prescribed quantity of the substance to be examined in *water R* and dilute to 10 ml with the same solvent or use 10 ml of the prescribed solution. Add 2 ml of a 200 g/l solution of *citric acid R* and 0.1 ml of *thioglycollic acid R*. Mix, make alkaline with *ammonia R* and dilute to 20 ml with *water R*. Prepare a standard in the same manner, using 10 ml of *iron standard solution (1 ppm Fe) R*.

After 5 min, any pink colour in the test solution is not more intense than that in the standard.

01/2008:20410

2.4.10. LEAD IN SUGARS

Determine the lead by atomic absorption spectrometry (*2.2.23, Method II*).

Test solution. Dissolve 20.0 g of the substance to be examined in a mixture of equal volumes of *dilute acetic acid R* and *water R* and dilute to 100.0 ml with the same mixture of solvents. Add 2.0 ml of a clear 10 g/l solution of *ammonium pyrrolidinedithiocarbamate R* and 10.0 ml of *methyl isobutyl ketone R* and then shake for 30 s protected from bright light. Allow the layers to separate and use the methyl isobutyl ketone layer.

Reference solutions. Prepare 3 reference solutions in the same manner as the test solution but adding 0.5 ml, 1.0 ml and 1.5 ml respectively of *lead standard solution (10 ppm Pb) R* in addition to the 20.0 g of the substance to be examined.

Set the zero of the instrument using *methyl isobutyl ketone R* treated as described for the test solution without the substance to be examined. Measure the absorbance at 283.3 nm using a lead hollow-cathode lamp as source of radiation and an air-acetylene flame.

The substance to be examined contains not more than 0.5 ppm of lead, unless otherwise prescribed.

01/2008:20411

2.4.11. PHOSPHATES

To 100 ml of the solution prepared and, if necessary, neutralised as prescribed add 4 ml of *sulphomolybdic reagent R3*. Shake and add 0.1 ml of *stannous chloride solution R1*. Prepare a standard in the same manner using 2 ml of *phosphate standard solution (5 ppm PO_4) R* and 98 ml of *water R*. After 10 min, compare the colours using 20 ml of each solution.

Any colour in the test solution is not more intense than that in the standard.

01/2008:20412

2.4.12. POTASSIUM

To 10 ml of the prescribed solution add 2 ml of a freshly prepared 10 g/l solution of *sodium tetraphenylborate R*. Prepare a standard in the same manner using a mixture of 5 ml of *potassium standard solution (20 ppm K) R* and 5 ml of *water R*.

After 5 min, any opalescence in the test solution is not more intense than that in the standard.

01/2008:20413

2.4.13. SULPHATES

All solutions used for this test must be prepared with distilled water R.

Add 3 ml of a 250 g/l solution of *barium chloride R* to 4.5 ml of *sulphate standard solution (10 ppm SO_4) R1*. Shake and allow to stand for 1 min. To 2.5 ml of this solution, add 15 ml of the solution to be examined and 0.5 ml of *acetic acid R*. Prepare a standard in the same manner using 15 ml of *sulphate standard solution (10 ppm SO_4) R* instead of the solution to be examined.

After 5 min, any opalescence in the test solution is not more intense than that in the standard.

01/2008:20414

2.4.14. SULPHATED ASH

Ignite a suitable crucible (for example, silica, platinum, porcelain or quartz) at 600 ± 50 °C for 30 min, allow to cool in a desiccator over silica gel or other suitable desiccant and weigh. Place the prescribed amount of the substance to be examined in the crucible and weigh. Moisten the substance to be examined with a small amount of *sulphuric acid R* (usually 1 ml) and heat gently at as low a temperature as practicable until the sample is thoroughly charred. After cooling, moisten the residue with a small amount of *sulphuric acid R* (usually 1 ml), heat gently until white fumes are no longer evolved and ignite at 600 ± 50 °C until the residue is completely incinerated. Ensure that flames are not produced at any time during the procedure. Allow the crucible to cool in a desiccator over silica gel or other suitable desiccant, weigh it again and calculate the percentage of residue.

If the amount of the residue so obtained exceeds the prescribed limit, repeat the moistening with *sulphuric acid R* and ignition, as previously, for 30 min periods until 2 consecutive weighings do not differ by more than 0.5 mg or until the percentage of residue complies with the prescribed limit.

The amount of substance used for the test (usually 1-2 g) is chosen so that at the prescribed limit the mass of the residue (usually about 1 mg) can be measured with sufficient accuracy.

01/2008:20415
corrected 6.0

2.4.15. NICKEL IN POLYOLS

Determine the nickel by atomic absorption spectrometry (*2.2.23, Method II*).

Test solution. Dissolve 20.0 g of the substance to be examined in a mixture of equal volumes of *dilute acetic acid R* and *water R* and dilute to 100.0 ml with the same mixture of solvents. Add 2.0 ml of a saturated solution of *ammonium pyrrolidinedithiocarbamate R* (about 10 g/l) and 10.0 ml of *methyl isobutyl ketone R* and then shake for 30 s protected from bright light. Allow the layers to separate and use the methyl isobutyl ketone layer.

Reference solutions. Prepare 3 reference solutions in the same manner as the test solution but adding 0.5 ml, 1.0 ml and 1.5 ml respectively of *nickel standard solution (10 ppm Ni) R* in addition to the 20.0 g of the substance to be examined.

Set the zero of the instrument using *methyl isobutyl ketone R* treated as described for preparation of the test solution omitting the substance to be examined. Measure the absorbance at 232.0 nm using a nickel hollow-cathode lamp as source of radiation and an air-acetylene flame.

The substance to be examined contains not more than 1.0 ppm of nickel, unless otherwise prescribed.

01/2008:20416

2.4.16. TOTAL ASH

Heat a silica or platinum crucible to redness for 30 min, allow to cool in a desiccator and weigh. Unless otherwise prescribed, evenly distribute 1.00 g of the substance or the powdered herbal drug to be examined in the crucible. Dry at 100 °C to 105 °C for 1 h and ignite to constant mass in a muffle furnace at 600 °C ± 25 °C, allowing the crucible to cool in a desiccator after each ignition. Flames should not be produced at any time during the procedure. If after prolonged ignition the ash still contains black particles, take up with hot water, filter through an ashless filter paper and ignite the residue and the filter paper. Combine the filtrate with the ash, carefully evaporate to dryness and ignite to constant mass.

01/2008:20417

2.4.17. ALUMINIUM

Place the prescribed solution in a separating funnel and shake with 2 quantities, each of 20 ml, and then with one 10 ml quantity of a 5 g/l solution of *hydroxyquinoline R* in *chloroform R*. Dilute the combined chloroform solutions to 50.0 ml with *chloroform R* (test solution).

Prepare a standard in the same manner using the prescribed reference solution.

Prepare a blank in the same manner using the prescribed blank solution.

Measure the intensity of the fluorescence (*2.2.21*) of the test solution (I_1), of the standard (I_2) and of the blank (I_3) using an excitant beam at 392 nm and a secondary filter with a transmission band centred on 518 nm or a monochromator set to transmit at this wavelength.

The fluorescence ($I_1 - I_3$) of the test solution is not greater than that of the standard ($I_2 - I_3$).

01/2008:20418

2.4.18. FREE FORMALDEHYDE

Use method A, unless otherwise prescribed. Method B is suitable for vaccines where sodium metabisulphite has been used to neutralise excess formaldehyde.

METHOD A

For vaccines for human use, prepare a 1 in 10 dilution of the vaccine to be examined. For bacterial toxoids for veterinary use, prepare a 1 in 25 dilution of the vaccine to be examined.

To 1 ml of the dilution, add 4 ml of *water R* and 5 ml of *acetylacetone reagent R1*. Place the tube in a water-bath at 40 °C for 40 min. Examine the tubes down their vertical axes. The solution is not more intensely coloured than a standard, prepared at the same time and in the same manner, using 1 ml of a dilution of *formaldehyde solution R* containing 20 µg of formaldehyde (CH_2O) per millilitre, instead of the dilution of the vaccine to be examined.

METHOD B

Test solution. Prepare a 1 in 200 dilution of the vaccine to be examined with *water R*. If the vaccine is an emulsion, prepare an equivalent dilution using the aqueous phase separated by a suitable procedure (see below). If one of the methods described below is used for separation of the aqueous phase, a 1 in 20 dilution of the latter is used.

Reference solutions. Prepare solutions containing 0.25 g/l, 0.50 g/l, 1.00 g/l and 2.00 g/l of CH_2O by dilution of *formaldehyde solution R* with *water R*. Prepare a 1 in 200 dilution of each solution with *water R*.

To 0.5 ml of the test solution and of each of the reference solutions in test-tubes, add 5.0 ml of a freshly prepared 0.5 g/l solution of *methylbenzothiazolone hydrazone hydrochloride R*. Close the tubes, shake and allow to stand for 60 min. Add 1 ml of *ferric chloride-sulphamic acid reagent R* and allow to stand for 15 min. Measure the absorbance (*2.2.25*) of the solutions at 628 nm. Calculate the content of formaldehyde in the vaccine to be examined from the calibration curve established using the reference solutions. The test is invalid if the correlation coefficient (r) of the calibration curve is less than 0.97.

Emulsions. If the vaccine to be examined is an emulsion, the aqueous phase is separated using a suitable procedure and used for preparation of the test solution. The following procedures have been found suitable.

(a) Add 1.0 ml of the vaccine to be examined to 1.0 ml of *isopropyl myristate R* and mix. Add 1.3 ml of *1 M hydrochloric acid*, 2.0 ml of *chloroform R* and 2.7 ml of a 9 g/l solution of *sodium chloride R*. Mix thoroughly. Centrifuge at 15 000 *g* for 60 min. Transfer the aqueous phase to a 10 ml volumetric flask and dilute to volume with *water R*. If this procedure fails to separate the aqueous phase, add 100 g/l of *polysorbate 20 R* to the sodium chloride solution and repeat the procedure but centrifuge at 22 500 *g*.

(b) Add 1.0 ml of the vaccine to be examined to 1.0 ml of a 100 g/l solution of *sodium chloride R* and mix. Centrifuge at 1000 *g* for 15 min. Transfer the aqueous phase to a 10 ml volumetric flask and dilute to volume with *water R*.

(c) Add 1.0 ml of the vaccine to be examined to 2.0 ml of a 100 g/l solution of *sodium chloride R* and 3.0 ml of *chloroform R* and mix. Centrifuge at 1000 *g* for 5 min. Transfer the aqueous phase to a 10 ml volumetric flask and dilute to volume with *water R*.

01/2008:20419

2.4.19. ALKALINE IMPURITIES IN FATTY OILS

In a test-tube mix 10 ml of recently distilled *acetone R* and 0.3 ml of *water R* and add 0.05 ml of a 0.4 g/l solution of *bromophenol blue R* in *alcohol R*. Neutralise the solution if necessary with *0.01 M hydrochloric acid* or *0.01 M sodium hydroxide*. Add 10 ml of the oil to be examined, shake and allow to stand. Not more than 0.1 ml of *0.01 M hydrochloric acid* is required to change the colour of the upper layer to yellow.

01/2008:20421

2.4.21. FOREIGN OILS IN FATTY OILS BY THIN-LAYER CHROMATOGRAPHY

Examine by thin-layer chromatography (*2.2.27*) using *kieselguhr G R* as the coating substance. Impregnate a plate by placing it in a chromatographic tank containing the necessary quantity of a mixture of 10 volumes of *liquid paraffin R* and 90 volumes of *light petroleum R* so that the plate dips about 5 mm beneath the surface of the liquid. When the impregnation mixture has risen by at least 12 cm from the lower edge of the plate, remove the plate and allow the solvent to evaporate for 5 min. Carry out the chromatography in the same direction as the impregnation.

Preparation of the mixture of fatty acids. Heat 2 g of the oil with 30 ml of *0.5 M alcoholic potassium hydroxide* under a reflux condenser for 45 min. Add 50 ml of *water R*, allow to cool, transfer to a separating funnel and extract with three quantities, each of 50 ml, of *ether R*. Discard the ether extracts, acidify the aqueous layer with *hydrochloric acid R* and extract with three quantities, each of 50 ml, of *ether R*. Combine the ether extracts and wash with three quantities, each of 10 ml, of *water R*; discard the washings, dry the ether over *anhydrous sodium sulphate R* and filter. Evaporate the ether on a water-bath. Use the residue to prepare the

test solution. The fatty acids may also be obtained from the soap solution prepared during the determination of the unsaponifiable matter.

Test solution. Dissolve 40 mg of the mixture of fatty acids obtained from the substance to be examined in 4 ml of *chloroform R*.

Reference solution. Dissolve 40 mg of the mixture of fatty acids obtained from a mixture of 19 volumes of *maize oil R* and 1 volume of *rapeseed oil R* in 4 ml of *chloroform R*.

Apply to the plate 3 µl of each solution. Develop over a path of 8 cm using a mixture of 10 volumes of *water R* and 90 volumes of *glacial acetic acid R*. Dry the plate at 110 °C for 10 min. Allow to cool and, unless otherwise prescribed, place the plate in a chromatographic chamber, with a tightly fitting lid, that has previously been saturated with iodine vapour by placing *iodine R* in an evaporating dish at the bottom of the chamber. After some time brown or yellowish-brown spots become visible. Remove the plate and allow to stand for a few minutes. When the brown background colour has disappeared, spray with *starch solution R*. Blue spots appear which may become brown on drying and again become blue after spraying with *water R*. The chromatogram obtained with the test solution always shows a spot with an R_F of about 0.5 (oleic acid) and a spot with an R_F of about 0.65 (linoleic acid) corresponding to the spots in the chromatogram obtained with the reference solution. With some oils a spot with an R_F of about 0.75 may be present (linolenic acid). By comparison with the spot in the chromatogram obtained with the reference solution, verify the absence in the chromatogram obtained with the test solution of a spot with an R_F of about 0.25 (erucic acid).

01/2008:20422

2.4.22. COMPOSITION OF FATTY ACIDS BY GAS CHROMATOGRAPHY

The test for foreign oils is carried out on the methyl esters of the fatty acids contained in the oil to be examined by gas chromatography (*2.2.28*).

METHOD A

This method is not applicable to oils that contain glycerides of fatty acids with an epoxy-, hydroepoxy-, hydroperoxy-, cyclopropyl or cyclopropenyl group, or those that contain a large proportion of fatty acids of chain length less than 8 carbon atoms or to oils with an acid value greater than 2.0.

Test solution. When prescribed in the monograph, dry the oil to be examined before the methylation step. Weigh 1.0 g of the oil into a 25 ml round-bottomed flask with a ground-glass neck fitted with a reflux condenser and a gas port into the flask. Add 10 ml of *anhydrous methanol R* and 0.2 ml of a 60 g/l solution of *potassium hydroxide R* in *methanol R*. Attach the reflux condenser, pass *nitrogen R* through the mixture at a rate of about 50 ml/min, shake and heat to boiling. When the solution is clear (usually after about 10 min), continue heating for a further 5 min. Cool the flask under running water and transfer the contents to a separating funnel. Rinse the flask with 5 ml of *heptane R* and transfer the rinsings to the separating funnel and shake. Add 10 ml of a 200 g/l solution of *sodium chloride R* and shake vigorously. Allow to separate and transfer the organic layer to a vial containing *anhydrous sodium sulphate R*. Allow to stand, then filter.

Reference solution (a). Prepare 0.50 g of the mixture of calibrating substances with the composition described in one of the 2.4.22 tables, as prescribed in the individual monograph (if the monograph does not mention a specific solution, use the composition described in Table 2.4.22.-1). Dissolve in *heptane R* and dilute to 50.0 ml with the same solvent.

Reference solution (b). Dilute 1.0 ml of reference solution (a) to 10.0 ml with *heptane R*.

Reference solution (c). Prepare 0.50 g of a mixture of fatty acid methyl esters that corresponds in composition to the mixture of fatty acids indicated in the monograph of the substance to be examined. Dissolve in *heptane R* and dilute to 50.0 ml with the same solvent. Commercially available mixtures of fatty acid methyl esters may also be used.

Column:

- *material*: fused silica, glass or quartz;
- *size*: *l* = 10-30 m, Ø = 0.2-0.8 mm;
- *stationary phase*: *macrogol 20 000 R* (film thickness 0.1-0.5 µm) or another suitable stationary phase.

Carrier gas: *helium for chromatography R* or *hydrogen for chromatography R*.

Flow rate: 1.3 ml/min (for a column Ø = 0.32 mm).

Split ratio: 1:100 or less, according to the internal diameter of the column used (1:50 when Ø = 0.32 mm).

Temperature:

- *column*: in isothermal conditions, 160-200 °C, according to the length and type of column used (200 °C for a column 30 m long and coated with a layer of *macrogol 20 000 R*); if a linear temperature programming is necessary, raise the temperature of the column at a rate of 3 °C/min from 170 °C to 230 °C, for example;
- *injection port*: 250 °C;
- *detector*: 250 °C.

Detection: flame ionisation.

Injection: 1 µl.

Sensitivity: the height of the principal peak in the chromatogram obtained with reference solution (a) is 50-70 per cent of the full scale of the recorder.

System suitability when using the mixture of calibrating substances in Table 2.4.22.-1 or Table 2.4.22.-3:

- *resolution*: minimum 1.8 between the peaks due to methyl oleate and methyl stearate in the chromatogram obtained with reference solution (a);
- *signal-to-noise ratio*: minimum 5 for the peak due to methyl myristate in the chromatogram obtained with reference solution (b);
- *number of theoretical plates*: minimum 30 000, calculated for the peak due to methyl stearate in the chromatogram obtained with reference solution (a).

System suitability when using the mixture of calibrating substances in Table 2.4.22.-2:

- *resolution*: minimum 4.0 between the peaks due to methyl caprylate and methyl caprate in the chromatogram obtained with reference solution (a);
- *signal-to-noise ratio*: minimum 5 for the peak due to methyl caproate in the chromatogram obtained with reference solution (b);
- *number of theoretical plates*: minimum 15 000, calculated for the peak due to methyl caprate in the chromatogram obtained with reference solution (a).

ASSESSMENT OF CHROMATOGRAMS

Avoid working conditions tending to give masked peaks (presence of constituents with small differences between retention times, for example linolenic acid and arachidic acid).

Qualitative analysis. Identify the peaks in the chromatogram obtained with reference solution (c) (isothermal operating conditions or linear temperature programming).

When using isothermal operating conditions, the peaks may also be identified by drawing calibration curves using the chromatogram obtained with reference solution (a) and the information given in Tables 2.4.22.-1, 2.4.22.-2 or 2.4.22.-3.

Table 2.4.22.-1. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

Mixture of the following substances	Composition (per cent *m/m*)
Methyl laurate R	5
Methyl myristate R	5
Methyl palmitate R	10
Methyl stearate R	20
Methyl arachidate R	40
Methyl oleate R	20

Table 2.4.22.-2. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

Mixture of the following substances	Composition (per cent *m/m*)
Methyl caproate R	10
Methyl caprylate R	10
Methyl caprate R	20
Methyl laurate R	20
Methyl myristate R	40

Table 2.4.22.-3. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

Mixture of the following substances	Composition (per cent *m/m*)
Methyl myristate R	5
Methyl palmitate R	10
Methyl stearate R	15
Methyl arachidate R	20
Methyl oleate R	20
Methyl eicosenoate R	10
Methyl behenate R	10
Methyl lignocerate R	10

Measure the reduced retention time (t'_R) of each peak in the chromatogram obtained with reference solution (a). t'_R is the retention time measured from the solvent peak and not from the time of injection. Plot the straight line:

$$\log (t'_R) = f \text{ (equivalent chain length)}$$

The logarithms of t'_R of unsaturated acids are situated on this line at points corresponding to non-integer values of carbon atoms known as 'equivalent chain lengths'; the equivalent chain length is the length of the theoretical saturated chain that would have the same t'_R as the fatty acid to be identified. For example, linoleic acid has the same t'_R as the theoretical saturated fatty acid having 18.8 carbon atoms.

Identify the peaks in the chromatogram obtained with the test solution by means of the straight line and the reduced retention times. Equivalent chain lengths are given in Table 2.4.22.-4.

Table 2.4.22.-4. – *Equivalent chain lengths (this value, which is to be calculated using calibration curves, is given as an example for a column of macrogol 20 000 R)*

Fatty acid	Equivalent chain length
Caproic acid	6.0
Caprylic acid	8.0
Capric acid	10.0
Lauric acid	12.0
Myristic acid	14.0
Palmitic acid	16.0
Palmitoleic acid	16.3
Margaric acid	17.0
Stearic acid	18.0
Oleic acid	18.3
Linoleic acid	18.8
Gamma-linolenic acid	19.0
Alpha-linolenic acid	19.2
Arachidic acid	20.0
Eicosenoic acid	20.2
Arachidonic acid	21.2
Behenic acid	22.0
Erucic acid	22.2
12-Oxostearic acid	22.7
Ricinoleic acid	23.9
12-Hydroxystearic acid	23.9
Lignoceric acid	24.0
Nervonic acid	24.2

Quantitative analysis. In general, the normalisation procedure is used in which the sum of the areas of the peaks in the chromatogram, except that of the solvent, is set at 100 per cent. The content of a constituent is calculated by determining the area of the corresponding peak as a percentage of the sum of the areas of all the peaks. Disregard any peak with an area less than 0.05 per cent of the total area.

In certain cases, for example in the presence of fatty acids with 12 or less carbon atoms, correction factors can be prescribed in the individual monograph to convert peak areas in per cent *m/m*.

METHOD B

This method is not applicable to oils that contain glycerides of fatty acids with an epoxy-, hydroepoxy-, hydroperoxy-, cyclopropyl or cyclopropenyl group or to oils with an acid value greater than 2.0.

Test solution. Introduce 0.100 g of the substance to be examined into a 10 ml centrifuge tube with a screw cap. Dissolve with 1 ml of *heptane R* and 1 ml of *dimethyl carbonate R* and mix vigorously under gentle heating (50-60 °C). Add, while still warm, 1 ml of a 12 g/l solution of *sodium R* in *anhydrous methanol R*, prepared with the necessary precautions, and mix vigorously for about 5 min. Add 3 ml of *distilled water R* and mix vigorously for about 30 s. Centrifuge for 15 min at 1500 *g*. Inject 1 µl of the organic phase.

Reference solutions and assessment of chromatograms. Where there is no specific prescription in the individual monograph, proceed as described under Method A.

Column:

– *material*: fused silica;
– *size*: *l* = 30 m, Ø = 0.25 mm;
– *stationary phase*: *macrogol 20 000 R* (film thickness 0.25 µm).

Carrier gas: *helium for chromatography R.*

Flow rate: 0.9 ml/min.

Split ratio: 1:100.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 15	100
	15 - 36	100 → 225
	36 - 61	225
Injection port		250
Detector		250

Detection: flame ionisation.

Injection: 1 µl.

METHOD C

This method is not applicable to oils that contain glycerides of fatty acids with epoxy-, hydroepoxy-, hydroperoxy-, aldehyde, ketone, cyclopropyl and cyclopropenyl groups, and conjugated polyunsaturated and acetylenic compounds because of partial or complete destruction of these groups.

Test solution. Dissolve 0.10 g of the substance to be examined in 2 ml of a 20 g/l solution of *sodium hydroxide R* in *methanol R* in a 25 ml conical flask and boil under a reflux condenser for 30 min. Add 2.0 ml of *boron trifluoride-methanol solution R* through the condenser and boil for 30 min. Add 4 ml of *heptane R* through the condenser and boil for 5 min. Cool and add 10.0 ml of *saturated sodium chloride solution R*, shake for about 15 s and add a quantity of *saturated sodium chloride solution R* such that the upper phase is brought into the neck of the flask. Collect 2 ml of the upper phase, wash with 3 quantities, each of 2 ml, of *water R* and dry over *anhydrous sodium sulphate R*.

Reference solutions, chromatographic procedure and assessment of chromatograms. Where there is no specific prescription in the individual monograph, proceed as described under Method A.

01/2008:20423

2.4.23. STEROLS IN FATTY OILS

SEPARATION OF THE STEROL FRACTION

Prepare the unsaponifiable matter and then isolate the sterol fraction of the fatty oil by thin-layer chromatography (*2.2.27*), using a *TLC silica gel plate R* with a 0.2 mm to 0.5 mm layer.

Test solution (a). In a 150 ml flask fitted with a reflux condenser, place a volume of a 2 g/l solution of *betulin R* in *methylene chloride R* containing betulin corresponding to about 10 per cent of the sterol content of the sample used for the determination (e.g. in the case of olive oil add 500 µl, in the case of other vegetable oils add 1500 µl of the betulin solution). If the monograph requires the percentage content of the individual sterols in the sterol fraction, the addition of betulin may be omitted. Evaporate to dryness under a current of *nitrogen R*. Add 5.00 g (*m*) of the substance to be examined. Add 50 ml of *2 M alcoholic potassium hydroxide R* and heat on a water-bath for 1 h, swirling frequently. Cool to a temperature below 25 °C and transfer the contents of the flask to a separating funnel with 100 ml of *water R*. Shake the liquid carefully with 3 quantities, each of 100 ml, of *peroxide-free ether R*. Combine the ether layers in another separating funnel containing 40 ml of *water R*, shake gently for a few minutes, allow to separate and reject the aqueous phase. Wash the ether phase with several quantities, each of 40 ml, of *water R*, until the aqueous phase is no longer alkaline to phenolphthalein. Transfer the ether phase to a tared flask, washing the separating funnel with *peroxide-free ether R*. Distil off the ether with suitable precautions and add 6 ml of *acetone R* to the residue. Carefully remove the solvent in a current of *nitrogen R*. Dry to constant mass at 100-105 °C. Allow to cool in a desiccator and weigh. Transfer the residue to a small test tube with *methylene chloride R*. Evaporate under a stream of *nitrogen R* to a volume of about 1 ml. Depending on the insaponifiable content of the oil, adapt the final concentration of the solution to 25-50 mg/ml.

Test solution (b). Treat 5.00 g of *rapeseed oil R* as prescribed for the substance to be examined, beginning at the words "Add 50 ml of *2 M alcoholic potassium hydroxide R*".

Test solution (c). Treat 5.00 g of *sunflower oil R* as prescribed for the substance to be examined, beginning at the words "Add 50 ml of *2 M alcoholic potassium hydroxide R*".

Reference solution. Dissolve 25 mg of *cholesterol R* and 10 mg of *betulin R* in 1 ml of *methylene chloride R*.

Use a separate plate for each test solution. Apply as a band of 10 mm, at 20 mm from the base and 10 mm from the left edge, 10 µl of the reference solution and as bands of 150 mm, at 20 mm from the base, 0.5 ml of test solutions (a), (b) or (c). Develop over a path of 17 cm using a mixture of 35 volumes of *ether R* and 65 volumes of *hexane R*. Dry the plates in a current of *nitrogen R*. Spray the plates with a 2 g/l solution of *dichlorofluorescein R* in *ethanol R* and examine in ultraviolet light at 254 nm. The chromatogram obtained with the reference solution shows bands corresponding to cholesterol and betulin. The chromatograms obtained with the test solutions show bands with similar R_F values due to sterols. From each of the chromatograms, remove an area of coating corresponding to the area occupied by the sterol bands and additionally the area of the zones 2-3 mm above and below the visible zones corresponding to the reference solution. Place separately in three 50 ml flasks. To each flask add 15 ml of *methylene chloride R* and heat under reflux with stirring, for 15 min. Filter each solution through a sintered-glass filter (40) (*2.1.2*) or suitable filter

paper and wash each filter with 3 quantities, each of 15 ml, of *methylene chloride R*. Place the combined filtrate and washings from each filter separately in 3 flasks, evaporate under a stream of *nitrogen R* to 5-10 ml. Transfer to a small test tube and evaporate to dryness under a stream of *nitrogen R*.

DETERMINATION OF THE STEROLS

Gas chromatography (*2.2.28*). *Carry out the operations protected from humidity and prepare the solutions immediately before use.*

Test solution. To the sterols separated from the substance to be examined by thin-layer chromatography add a freshly prepared mixture of 0.04 ml of *chlorotrimethylsilane R*, 0.1 ml of *hexamethyldisilazane R* and 0.5 ml of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

Reference solution (a). To 9 parts of the sterols separated from *rapeseed oil R* by thin-layer chromatography add 1 part of *cholesterol R*. To the mixture add a freshly prepared mixture of 0.04 ml of *chlorotrimethylsilane R*, 0.1 ml of *hexamethyldisilazane R* and 0.5 ml of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

Reference solution (b). To the sterols separated from *sunflower oil R* by thin-layer chromatography add a freshly prepared mixture of 0.04 ml of *chlorotrimethylsilane R*, 0.1 ml of *hexamethyldisilazane R* and 0.5 ml of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

Column:

– *material*: fused silica,

– *size*: *l* = 20-30 m, Ø = 0.25-0.32 mm,

– *stationary phase*: *poly[methyl(95)phenyl(5)]siloxane R* or *poly(cyanopropyl)(7)(phenyl)(7)(methyl)(86)siloxane R* (film thickness 0.25 µm).

Carrier gas: *hydrogen for chromatography R* or *helium for chromatography R*.

Linear velocity: 30-50 cm/s (hydrogen) or 20-35 cm/s (helium).

Split ratio: 1:50 or 1:100.

Temperature:

– *column*: 260 °C,

– *injection port*: 280 °C,

– *detector*: 290 °C.

Detection: flame ionisation.

Injection: 1 µl.

Results: the chromatogram obtained with reference solution (a) shows 4 principal peaks corresponding to cholesterol, brassicasterol, campesterol and β-sitosterol and the chromatogram obtained with reference solution (b) shows 4 principal peaks corresponding to campesterol, stigmasterol, β-sitosterol and Δ7-stigmastenol. The retention times of the sterols with reference to β-sitosterol are given in Table 2.4.23.-1.

Table 2.4.23.-1. – *Retention times of sterols with reference to β-sitosterol for two different columns*

	Poly(cyanopropyl)(7)-(phenyl)(7)-(methyl)(86)siloxane	Poly[methyl(95)-phenyl(5)]siloxane
Cholesterol	0.64	0.63
Brassicasterol	0.70	0.71
24-Methylenecholesterol	0.79	0.80
Campesterol	0.82	0.81
Campestanol	0.83	0.82
Stigmasterol	0.87	0.87
Δ7-Campesterol	0.93	0.92
Δ5,23-Stigmastadienol	0.95	0.95
Clerosterol	0.96	0.96
β-Sitosterol	1	1
Sitostanol	1.01	1.02
Δ5-Avenasterol	1.03	1.03
Δ5,24-Stigmastadienol	1.09	1.08
Δ7-Stigmastenol(1)	1.13	1.12
Δ7-Avenasterol	1.18	1.16
Betulin	1.4	1.4

(1) This sterol may also be referred to as Δ7-stigmasterol in literature.

The peak of the internal standard (betulin) must be clearly separated from the peaks of the sterols to be determined.

For the chromatogram obtained with the test solution, identify the peaks and calculate the percentage content of each sterol in the sterol fraction of the substance to be examined using the following expression:

$$\frac{A}{S} \times 100$$

A = area of the peak due to the component to be determined,

S = sum of the areas of the peaks due to the components indicated in Table 2.4.23.-1.

If required in the monograph, calculate the content of each sterol in milligrams per 100 grams of the substance to be examined using the following expression:

$$\frac{A \times m' \times 100}{A' \times m}$$

A = area of the peak due to the component to be determined,

A' = area of the peak due to betulin,

m = mass of the sample of the substance to be examined in grams,

m' = mass of *betulin R* added in milligrams.

01/2008:20424

2.4.24. IDENTIFICATION AND CONTROL OF RESIDUAL SOLVENTS

The test procedures described in this general method may be used:

i. for the identification of the majority of Class 1 and Class 2 residual solvents in an active substance, excipient or medicinal product when the residual solvents are unknown;

ii. as a limit test for Class 1 and Class 2 solvents when present in an active substance, excipient or medicinal product;

iii. for the quantification of Class 2 solvents when the limits are greater than 1000 ppm (0.1 per cent) or for the quantification of Class 3 solvents when required.

Class 1, Class 2 and Class 3 residual solvents are listed in general chapter *5.4. Residual solvents*.

Three diluents are described for sample preparation and the conditions to be applied for head-space injection of the gaseous sample onto the chromatographic system. Two chromatographic systems are prescribed but System A is preferred whilst System B is employed normally for confirmation of identity. The choice of sample preparation procedure depends on the solubility of the substance to be examined and in certain cases the residual solvents to be controlled.

The following residual solvents are not readily detected by the head-space injection conditions described: formamide, 2-ethoxyethanol, 2-methoxyethanol, ethylene glycol, *N*-methylpyrrolidone and sulfolane. Other appropriate procedures should be employed for the control of these residual solvents.

When the test procedure is applied quantitatively to control residual solvents in a substance, then it must be validated.

PROCEDURE

Examine by gas chromatography with static head-space injection (*2.2.28*).

Sample preparation 1. This is intended for the control of residual solvents in water-soluble substances.

Sample solution (1). Dissolve 0.200 g of the substance to be examined in *water R* and dilute to 20.0 ml with the same solvent.

Sample preparation 2. This is intended for the control of residual solvents in water-insoluble substances.

Sample solution (2). Dissolve 0.200 g of the substance to be examined in *N,N-dimethylformamide R* (DMF) and dilute to 20.0 ml with the same solvent.

Sample preparation 3. This is intended for the control of *N,N*-dimethylacetamide and/or *N,N*-dimethylformamide, when it is known or suspected that one or both of these substances are present in the substance to be examined.

Sample solution (3). Dissolve 0.200 g of the substance to be examined in *1,3-dimethyl-2-imidazolidinone R* (DMI) and dilute to 20.0 ml with the same solvent.

In some cases none of the above sample preparation procedures are appropriate, in which case the diluent to be used for the preparation of the sample solution and the static head-space conditions to be employed must be demonstrated to be suitable.

Solvent solution (a). To 1.0 ml of *Class 1 residual solvent solution CRS*, add 9 ml of *dimethyl sulphoxide R* and dilute to 100.0 ml with *water R*. Dilute 1.0 ml of this solution to 100 ml with *water R*. Dilute 1.0 ml of this solution to 10.0 ml with *water R*.

The reference solutions correspond to the following limits:

- benzene: 2 ppm,
- carbon tetrachloride: 4 ppm,
- 1,2-dichloroethane: 5 ppm,
- 1,1-dichloroethene: 8 ppm,
- 1,1,1-trichloroethane: 10 ppm.

Solvent solution (b). Dissolve appropriate quantities of the Class 2 residual solvents in *dimethyl sulphoxide R* and dilute to 100.0 ml with *water R*. Dilute to give a concentration of 1/20 of the limits stated in Table 2 (see *5.4. Residual solvents*).

Solvent solution (c). Dissolve 1.00 g of the solvent or solvents present in the substance to be examined in *dimethyl sulphoxide R* or *water R*, if appropriate, and dilute to 100.0 ml with *water R*. Dilute to give a concentration of 1/20 of the limit(s) stated in Table 1 or 2 (see *5.4. Residual solvents*).

Blank solution. Prepare as described for solvent solution (c) but without the addition of solvent(s) (used to verify the absence of interfering peaks).

Test solution. Introduce 5.0 ml of the sample solution and 1.0 ml of the blank solution into an injection vial.

Reference solution (a) (Class 1). Introduce 1.0 ml of solvent solution (a) and 5.0 ml of the appropriate diluent into an injection vial.

Reference solution (a_1) (Class 1). Introduce 5.0 ml of the sample solution and 1.0 ml of solvent solution (a) into an injection vial.

Reference solution (b) (Class 2). Introduce 1.0 ml of solvent solution (b) and 5.0 ml of the appropriate diluent into an injection vial.

Reference solution (c). Introduce 5.0 ml of the sample solution and 1.0 ml of solvent solution (c) into an injection vial.

Reference solution (d). Introduce 1.0 ml of the blank solution and 5.0 ml of the appropriate diluent into an injection vial.

Close the vials with a tight rubber membrane stopper coated with polytetrafluoroethylene and secure with an aluminium crimped cap. Shake to obtain a homogeneous solution.

The following static head-space injection conditions may be used:

	Sample preparation procedure		
Operating parameters	**1**	**2**	**3**
Equilibration temperature (°C)	80	105	80
Equilibration time (min)	60	45	45
Transfer-line temperature (°C)	85	110	105
Carrier gas: *Nitrogen for chromatography R* or *Helium for chromatography R* at an appropriate pressure			
Pressurisation time (s)	30	30	30
Injection volume (ml)	1	1	1

The chromatographic procedure may be carried out using:

SYSTEM A

- a fused-silica capillary or wide-bore column 30 m long and 0.32 mm or 0.53 mm in internal diameter coated with cross-linked 6 per cent polycyanopropylphenylsiloxane and 94 per cent polydimethylsiloxane (film thickness: 1.8 µm or 3 µm),
- *nitrogen for chromatography R* or *helium for chromatography R* as the carrier gas, split ratio 1:5 with a linear velocity of about 35 cm/s,
- a flame-ionisation detector (a mass spectrometer may also be used or an electron-capture detector for the chlorinated residual solvents of Class 1),

maintaining the temperature of the column at 40 °C for 20 min, then raising the temperature at a rate of 10 °C per min to 240 °C and maintaining it at 240 °C for 20 min and maintaining the temperature of the injection port at 140 °C and that of the detector at 250 °C, or, where there is interference from the matrix, use:

SYSTEM B

– a fused-silica capillary or wide-bore column 30 m long and 0.32 mm or 0.53 mm in internal diameter coated with *macrogol 20 000 R* (film thickness: 0.25 µm),
– *nitrogen for chromatography R* or *helium for chromatography R* as the carrier gas, split ratio 1:5 with a linear velocity of about 35 cm/s.
– a flame-ionisation detector (a mass spectrophotometer may also be used or an electron-capture detector for the chlorinated residual solvents of Class 1),

maintaining the temperature of the column at 50 °C for 20 min, then raising the temperature at a rate of 6 °C per min to 165 °C and maintaining it at 165 °C for 20 min and maintaining the temperature of the injection port at 140 °C and that of the detector at 250 °C.

Inject 1 ml of the gaseous phase of reference solution (a) onto the column described in System A and record the chromatogram under such conditions that the signal-to-noise ratio for 1,1,1-trichloroethane can be measured. The signal-to-noise ratio must be at least five. A typical chromatogram is shown in Figure 2.4.24.-1.

Inject 1 ml of the gaseous phase of reference solution (a_1) onto the column described in System A. The peaks due to the Class 1 residual solvents are still detectable.

Inject 1 ml of the gaseous phase of reference solution (b) onto the column described in System A and record the chromatogram under such conditions that the resolution between acetonitrile and methylene chloride can be determined. The system is suitable if the chromatogram obtained resembles the chromatogram shown in Figure 2.4.24.-2 and the resolution between acetonitrile and methylene chloride is at least 1.0.

Inject 1 ml of the gaseous phase of the test solution onto the column described in System A. If in the chromatogram obtained, there is no peak which corresponds to one of the residual solvent peaks in the chromatograms obtained with reference solution (a) or (b), then the substance to be examined meets the requirements of the test. If any peak in the chromatogram obtained with the test solution corresponds to any of the residual solvent peaks obtained with reference solution (a) or (b) then System B is to be employed.

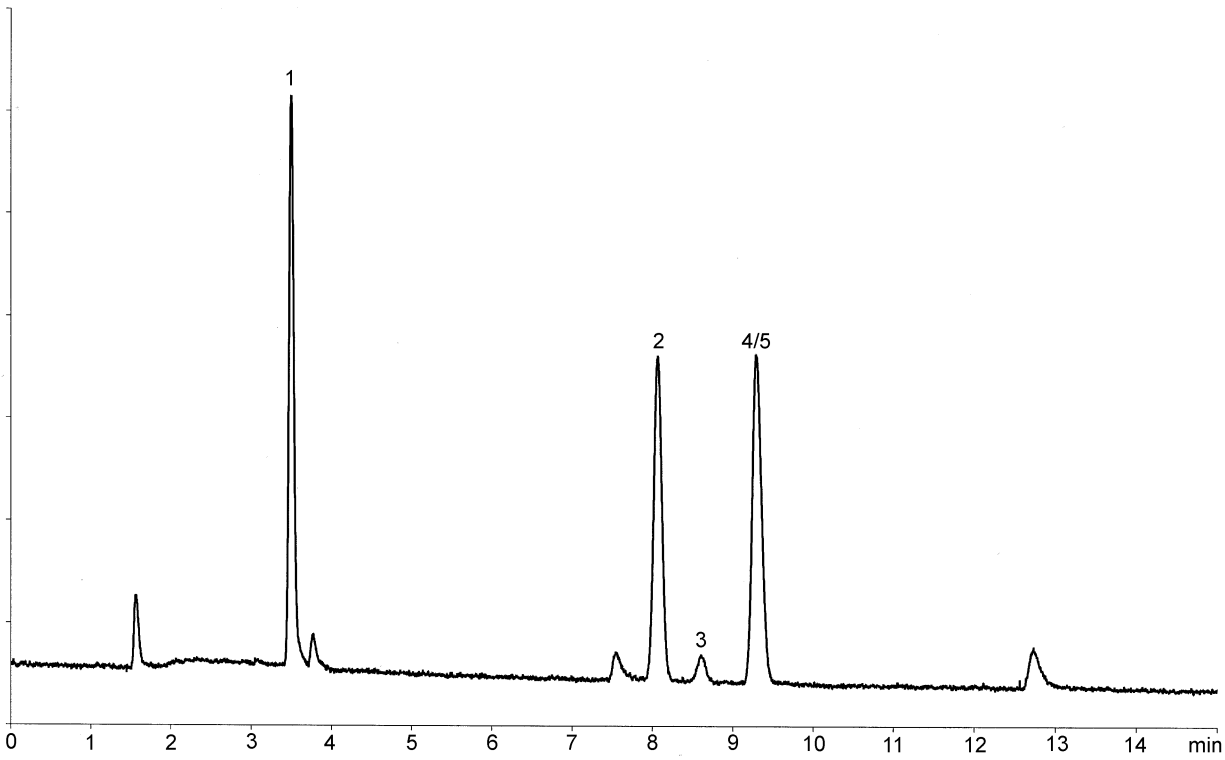
Inject 1 ml of the gaseous phase of reference solution (a) onto the column described in System B and record the chromatogram under such conditions that the signal-to-noise ratio for benzene can be measured. The signal-to-noise ratio must be at least five. A typical chromatogram is shown in Figure 2.4.24.-3.

Inject 1 ml of the gaseous phase of reference solution (a_1) onto the column described in System B. The peaks due to the Class I residual solvents are still detectable.

Inject 1 ml of the gaseous phase of reference solution (b) onto the column described in System B and record the chromatogram under such conditions that the resolution between acetonitrile and trichloroethene can be determined. The system is suitable if the chromatogram obtained resembles the chromatogram shown in Figure 2.4.24.-4 and the resolution between acetonitrile and trichloroethene is at least 1.0.

Inject 1 ml of the gaseous phase of the test solution onto the column described in System B. If in the chromatogram obtained, there is no peak which corresponds to any of the residual solvent peaks in the chromatogram obtained with the reference solution (a) or (b), then the substance to be examined meets the requirements of the test. If any peak in the chromatogram obtained with the test solution corresponds to any of the residual solvent peaks obtained with reference solution (a) or (b) and confirms the correspondence obtained when using System A, then proceed as follows.

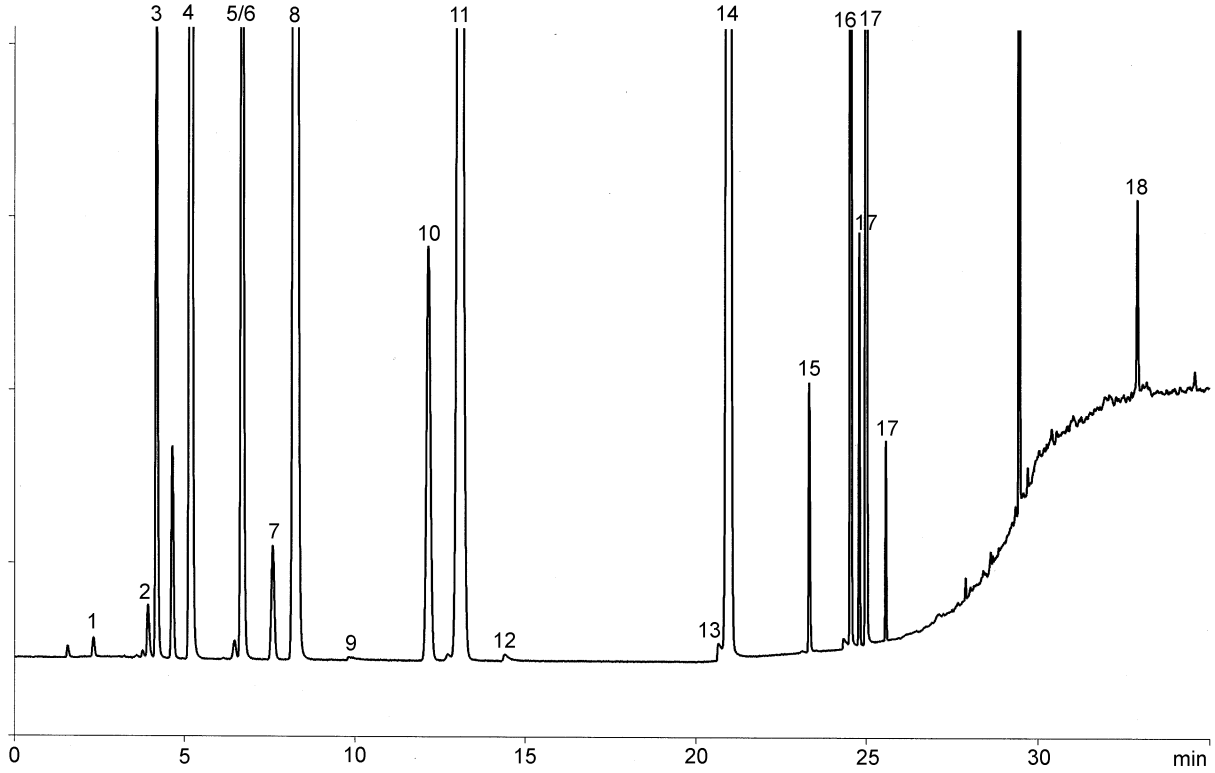
Inject 1 ml of the gaseous phase of reference solution (c) onto the column described for System A or System B. If necessary, adjust the sensitivity of the system so that the height of the peak corresponding to the identified residual solvent(s) is at least 50 per cent of the full scale of the recorder.



Inject 1 ml of the gaseous phase of reference solution (d) onto the column. No interfering peaks should be observed.

Inject 1 ml of the gaseous phase of the test solution and 1 ml of the gaseous phase of reference solution (c) on to the column. Repeat these injections twice more.

The mean area of the peak of the residual solvent(s) in the chromatograms obtained with the test solution is not greater than half the mean area of the peak of the corresponding residual solvent(s) in the chromatograms obtained with reference solution (c). The test is not valid unless the relative standard deviation of the differences in areas between the analyte peaks obtained from three replicate paired injections of reference solution (c) and the test solution, is at most 15 per cent.



A flow diagram of the procedure is shown in Figure 2.4.24.-5.

When a residual solvent (Class 2 or Class 3) is present at a level of 0.1 per cent or greater then the content may be quantitatively determined by the method of standard additions.

2.4.25. ETHYLENE OXIDE AND DIOXAN

The test is intended for the determination of residual ethylene oxide and dioxan in samples soluble in water or dimethylacetamide. For substances that are insoluble or insufficiently soluble in these solvents, the preparation of the sample solution and the head-space conditions to be employed are given in the individual monograph.

Examine by head-space gas chromatography (*2.2.28*).

A. For samples soluble in or miscible with water, the following procedure may be used.

Test solution. Weigh 1.00 g (M_T) of the substance to be examined in a 10 ml vial (other sizes may be used depending on the operating conditions) and add 1.0 ml of *water R*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

Reference solution (a). Weigh 1.00 g (M_R) of the substance to be examined into an identical 10 ml vial, add 0.50 ml of *ethylene oxide solution R3* and 0.50 ml of *dioxan solution R1*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

Reference solution (b). To 0.50 ml of *ethylene oxide solution R3* in a 10 ml vial add 0.1 ml of a freshly prepared 10 mg/l solution of *acetaldehyde R* and 0.1 ml of *dioxan solution R1*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

B. For samples soluble in or miscible with dimethylacetamide, the following procedure may be used.

Test solution. Weigh 1.00 g (M_T) of the substance to be examined in a 10 ml vial (other sizes may be used depending on the operating conditions) and add 1.0 ml of *dimethylacetamide R* and 0.20 ml of *water R*. Close and mix to obtain a homogeneous solution. Allow to stand at 90 °C for 45 min.

Reference solution (a). Weigh 1.00 g (M_R) of the substance to be examined into a 10 ml vial, add 1.0 ml of *dimethylacetamide R*, 0.10 ml of *dioxan solution R* and 0.10 ml of *ethylene oxide solution R2*. Close and mix to obtain a homogeneous solution. Allow to stand at 90 °C for 45 min.

Reference solution (b). To 0.10 ml of *ethylene oxide solution R2* in a 10 ml vial, add 0.1 ml of a freshly prepared 10 mg/l solution of *acetaldehyde R* and 0.10 ml of *dioxan solution R*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

The following static head-space injection conditions may be used:

- equilibration temperature: 70 °C (90 °C for solutions in dimethylacetamide),
- equilibration time: 45 min,
- transfer-line temperature: 75 °C (150 °C for solutions in dimethylacetamide),
- carrier gas: *helium for chromatography R*,
- pressurisation time: 1 min,
- injection time: 12 s.

The chromatographic procedure may be carried out using:

- a capillary glass or quartz column 30 m long and 0.32 mm in internal diameter the inner surface of which is coated with a 1.0 µm thick layer of *poly(dimethyl)siloxane R*,
- *helium for chromatography R* or *nitrogen for chromatography R* as the carrier gas with a linear velocity of about 20 cm/s and a split ratio of 1:20,
- a flame-ionisation detector,

maintaining the temperature of the column at 50 °C for 5 min, then raising the temperature at a rate of 5 °C per minute to 180 °C and then raising the temperature at a rate of 30 °C per minute to 230 °C and maintaining at 230 °C for 5 min; maintaining the temperature of the injection port at 150 °C and that of the detector at 250 °C.

Inject a suitable volume, for example 1.0 ml, of the gaseous phase of reference solution (b). Adjust the sensitivity of the system so that the heights of the peaks due to ethylene oxide and acetaldehyde in the chromatogram obtained are at least 15 per cent of the full scale of the recorder. The test is not valid unless the resolution between the peaks corresponding to acetaldehyde and ethylene oxide is at least 2.0 and the peak of dioxan is detected with a signal-to-noise ratio of at least 5.

Inject separately suitable volumes, for example 1.0 ml (or the same volume used for reference solution (b)), of the gaseous phases of the test solution and reference solution (a). Repeat the procedure twice more.

Verification of precision

For each pair of injections, calculate for ethylene oxide and for dioxan the difference in area between the peaks obtained with the test solution and reference solution (a). The test is not valid unless the relative standard deviation of the 3 values obtained for ethylene oxide is not greater than 15 per cent and the relative standard deviation of the 3 values obtained for dioxan is not greater than 10 per cent. If the weighings used for the test solution and reference solution differ from 1.00 g by more than 0.5 per cent, the appropriate corrections must be made.

The content of ethylene oxide or dioxan in parts per million is calculated from the expressions:

$$\frac{A_T \times C}{(A_R \times M_T) - (A_T \times M_R)}$$

A_T = area of the peak corresponding to ethylene oxide in the chromatogram obtained with the test solution,

A_R = area of the peak corresponding to ethylene oxide in the chromatogram obtained with reference solution (a),

M_T = mass of the substance to be examined in the test solution, in grams,

M_R = mass of the substance to be examined in the reference solution, in grams,

C = the amount of ethylene oxide added to reference solution (a), in micrograms.

$$\frac{D_T \times C}{(D_R \times M_T) - (D_T \times M_R)}$$

D_T = area of the peak corresponding to dioxan in the chromatogram obtained with the test solution,

D_R = area of the peak corresponding to dioxan in the chromatogram obtained with reference solution (a),

C = the amount of dioxan added to reference solution (a) in micrograms.

01/2008:20426

2.4.26. *N,N*-DIMETHYLANILINE

METHOD A

Examine by gas chromatography (*2.2.28*), using *N,N-diethylaniline R* as the internal standard.

Internal standard solution. Dissolve 50 mg of *N,N-diethylaniline R* in 4 ml of *0.1 M hydrochloric acid* and dilute to 50 ml with *water R*. Dilute 1 ml of this solution to 100 ml with *water R*.

Test solution. Dissolve in a ground-glass-stoppered tube 0.50 g of the substance to be examined in 30.0 ml of *water R*. Add 1.0 ml of the internal standard solution. Adjust the solution to a temperature of 26 °C to 28 °C. Add 1.0 ml of *strong sodium hydroxide solution R* and mix until

completely dissolved. Add 2.0 ml of *trimethylpentane R*. Shake for 2 min and allow the phases to separate. Use the upper layer.

Reference solution. Dissolve 50.0 mg of *N,N-dimethylaniline R* in 4.0 ml of *0.1 M hydrochloric acid* and dilute to 50.0 ml with *water R*. Dilute 1.0 ml of this solution to 100.0 ml with *water R*. Dilute 1.0 ml of this solution to 30.0 ml with *water R*. Add 1.0 ml of the internal standard solution and 1.0 ml of *strong sodium hydroxide solution R*. Add 2.0 ml of *trimethylpentane R*. Shake for 2 min and allow the phases to separate. Use the upper layer.

The chromatographic procedure may be carried out using:

- a fused-silica capillary column 25 m long and 0.32 mm in internal diameter coated with cross-linked *polymethylphenylsiloxane R* (film thickness 0.52 µm),
- *helium for chromatography R* as the carrier gas with a split ratio 1:20, a column head pressure of 50 kPa and a split vent of 20 ml/min,
- a flame-ionisation detector,
- a split-liner consisting of a column about 1 cm long packed with *diatomaceous earth for gas chromatography R* impregnated with 10 per cent *m/m* of *poly(dimethyl)siloxane R*,

maintaining the temperature of the column at 150 °C for 5 min, then raising the temperature at a rate of 20 °C per min to 275 °C and maintaining it at 275 °C for 3 min and maintaining the temperature of the detector at 300 °C and that of the injection port at 220 °C.

The retention times are: *N,N*-dimethylaniline about 3.6 min, *N,N*-diethylaniline about 5.0 min.

Inject 1 µl of the test solution and 1 µl of the reference solution.

METHOD B

Examined by gas chromatography (*2.2.28*), using *naphthalene R* as the internal standard.

Internal standard solution. Dissolve 50 mg of *naphthalene R* in *cyclohexane R* and dilute to 50 ml with the same solvent. Dilute 5 ml of this solution to 100 ml with *cyclohexane R*.

Test solution. To 1.00 g of the substance to be examined in a ground-glass-stoppered tube add 5 ml of *1 M sodium hydroxide* and 1.0 ml of the internal standard solution. Stopper the tube and shake vigorously for 1 min. Centrifuge if necessary and use the upper layer.

Reference solution. To 50.0 mg of *N,N-dimethylaniline R* add 2 ml of *hydrochloric acid R* and 20 ml of *water R*, shake to dissolve and dilute to 50.0 ml with *water R*. Dilute 5.0 ml of this solution to 250.0 ml with *water R*. To 1.0 ml of the latter solution in a ground-glass-stoppered tube add 5 ml of *1 M sodium hydroxide* and 1.0 ml of the internal standard solution. Stopper the tube and shake vigorously for 1 min. Centrifuge if necessary and use the upper layer.

The chromatographic procedure may be carried out using:

- a glass column 2 m long and 2 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 3 per cent *m/m* of *polymethylphenylsiloxane R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 120 °C and that of the injection port and of the detector at 150 °C.

Inject 1 µl of the test solution and 1 µl of the reference solution.

01/2008:20427

2.4.27. HEAVY METALS IN HERBAL DRUGS AND FATTY OILS

Examine by atomic absorption spectrometry (*2.2.23*).

CAUTION: when using closed high-pressure digestion vessels and microwave laboratory equipment, be familiar with the safety and operating instructions given by the manufacturer.

APPARATUS

The apparatus typically consists of the following:

- as digestion flasks, polytetrafluoroethylene flasks with a volume of about 120 ml, fitted with an airtight closure, a valve to adjust the pressure inside the container and a polytetrafluoroethylene tube to allow release of gas,
- a system to make flasks airtight, using the same torsional force for each of them,
- a microwave oven, with a magnetron frequency of 2450 MHz, with a selectable output from 0 to 630 ± 70 W in 1 per cent increments, a programmable digital computer, a polytetrafluoroethylene-coated microwave cavity with a variable speed exhaust fan, a rotating turntable drive system and exhaust tubing to vent fumes,
- an atomic absorption spectrometer, equipped with hollow-cathode lamps as source of radiation and a deuterium lamp as background corrector; the system is fitted with:

  (a) a graphite furnace as atomisation device for cadmium, copper, iron, lead, nickel and zinc.

  (b) an automated continuous-flow hydride vapour generation system for arsenic and mercury.

METHOD

In case alternative apparatus is used, an adjustment of the instrument parameters may be necessary.

Clean all the glassware and laboratory equipment with a 10 g/l solution of *nitric acid R* before use.

Test solution. In a digestion flask place the prescribed quantity of the substance to be examined (about 0.50 g of powdered drug (1400) (*2.9.12*) or 0.50 g of fatty oil). Add 6 ml of *heavy metal-free nitric acid R* and 4 ml of *heavy metal-free hydrochloric acid R*. Make the flask airtight.

Place the digestion flasks in the microwave oven. Carry out the digestion in 3 steps according to the following programme, used for 7 flasks each containing the test solution: 80 per cent power for 15 min, 100 per cent power for 5 min, 80 per cent power for 20 min.

At the end of the cycle allow the flasks to cool in air and to each add 4 ml of *heavy metal-free sulphuric acid R*. Repeat the digestion programme. After cooling in air, open each digestion flask and introduce the clear, colourless solution obtained into a 50 ml volumetric flask. Rinse each digestion flask with 2 quantities, each of 15 ml, of *water R* and collect the rinsings in the volumetric flask. Add 1.0 ml of a 10 g/l solution of *magnesium nitrate R* and 1.0 ml of a 100 g/l solution of *ammonium dihydrogen phosphate R* and dilute to 50.0 ml with *water R*.

Blank solution. Mix 6 ml of *heavy metal-free nitric acid R* and 4 ml of *heavy metal-free hydrochloric acid R* in a digestion flask. Carry out the digestion in the same manner as for the test solution.

CADMIUM, COPPER, IRON, LEAD, NICKEL AND ZINC

Measure the content of cadmium, copper, iron, lead, nickel and zinc by the standard additions method (*2.2.23, Method II*), using reference solutions of each heavy metal and the instrumental parameters described in Table 2.4.27.-1.

The absorbance value of the blank solution is automatically subtracted from the value obtained with the test solution.

Table 2.4.27.-1

		Cd	Cu	Fe	Ni	Pb	Zn
Wavelength	nm	228.8	324.8	248.3	232	283.5	213.9
Slit width	nm	0.5	0.5	0.2	0.2	0.5	0.5

Ignition temperature	°C	800	800	800	800	800	800
Atomisation temperature	°C	1800	2300	2300	2500	2200	2000
Background corrector		on	off	off	off	off	off
Nitrogen flow	l/min	3	3	3	3	3	3

ARSENIC AND MERCURY

Measure the content of arsenic and mercury in comparison with the reference solutions of arsenic or mercury at a known concentration by direct calibration (*2.2.23, Method I*) using an automated continuous-flow hydride vapour generation system.

The absorbance value of the blank solution is automatically subtracted from the value obtained with the test solution.

Arsenic

Sample solution. To 19.0 ml of the test solution or of the blank solution as prescribed above, add 1 ml of a 200 g/l solution of *potassium iodide R*. Allow the test solution to stand at room temperature for about 50 min or at 70 °C for about 4 min.

Acid reagent. Heavy metal-free hydrochloric acid R.

Reducing reagent. A 6 g/l solution of *sodium tetrahydroborate R* in a 5 g/l solution of *sodium hydroxide R*.

The instrumental parameters in Table 2.4.27.-2 may be used.

Mercury

Sample solution. Test solution or blank solution, as prescribed above.

Acid reagent. A 515 g/l solution of *heavy metal-free hydrochloric acid R*.

Reducing reagent. A 10 g/l solution of *stannous chloride R* in *dilute heavy metal-free hydrochloric acid R*.

The instrumental parameters in Table 2.4.27.-2 may be used.

Table 2.4.27.-2

		As	Hg
Wavelength	nm	193.7	253.7
Slit width	nm	0.2	0.5
Lamp current	mA	10	4
Acid reagent flow rate	ml/min	1.0	1.0
Reducing reagent flow rate	ml/min	1.0	1.0
Sample solution flow rate	ml/min	7.0	7.0

Background corrector		off	off
Nitrogen flow rate	l/min	0.1	0.1

01/2008:20428

2.4.28. 2-ETHYLHEXANOIC ACID

Examine by gas chromatography (*2.2.28*), using *3-cyclohexylpropionic acid R* as the internal standard.

Internal standard solution. Dissolve 100 mg of *3-cyclohexylpropionic acid R* in *cyclohexane R* and dilute to 100 ml with the same solvent.

Test solution. To 0.300 g of the substance to be examined, add 4.0 ml of a 33 per cent *V/V* solution of *hydrochloric acid R*. Shake vigorously for 1 min with 1.0 ml of the internal standard solution. Allow the phases to separate (if necessary, centrifuge for a better separation). Use the upper layer.

Reference solution. Dissolve 75.0 mg of *2-ethylhexanoic acid R* in the internal standard solution and dilute to 50.0 ml with the same solution. To 1.0 ml of the solution add 4.0 ml of a 33 per cent *V/V* solution of *hydrochloric acid R*. Shake vigorously for 1 min. Allow the phases to separate (if necessary, centrifuge for a better separation). Use the upper layer.

The chromatographic procedure may be carried out using:

- a wide-bore fused-silica column 10 m long and 0.53 mm in internal diameter coated with *macrogol 20 000 2-nitroterephthalate R* (film thickness 1.0 µm),
- *helium for chromatography R* as the carrier gas at a flow rate of 10 ml/min,
- a flame-ionisation detector,

with the following temperature programme:

	Time (min)	Temperature (°C)	Rate (°C/min)	Comment
Column	0 - 2	40	–	isothermal
	2 - 7.3	40 → 200	30	linear gradient
	7.3 - 10.3	200	–	isothermal
Injection port		200		
Detector		300		

Inject 1 µl of the test solution and 1 µl of the reference solution.

The test is not valid unless the resolution between the peaks corresponding to 2-ethylhexanoic acid (first peak) and the internal standard is at least 2.0.

Calculate the percentage content of 2-ethylhexanoic acid from the expression:

$$\frac{A_T \times I_R \times m_R \times 2}{A_R \times I_T \times m_T}$$

A_T = area of the peak corresponding to 2-ethylhexanoic acid in the chromatogram obtained with the test solution,

A_R = area of the peak corresponding to 2-ethylhexanoic acid in the chromatogram obtained with the reference solution,

I_T = area of the peak corresponding to the internal standard in the chromatogram obtained with the test solution,

I_R = area of the peak corresponding to the internal standard in the chromatogram obtained with the reference solution,

m_T = mass of the substance to be examined in the test solution, in grams,

m_R = mass of 2-ethylhexanoic acid in the reference solution, in grams.

01/2008:20429
corrected 6.0

2.4.29. COMPOSITION OF FATTY ACIDS IN OILS RICH IN OMEGA-3 ACIDS

The assay may be used for quantitative determination of the EPA and DHA content in omega-3-containing products of fish oil in different concentrations. The method is applicable to triglycerides or ethyl esters and the results are expressed as triglycerides or ethyl esters, respectively.

EPA AND DHA

Gas chromatography (*2.2.28*). *Carry out the operations as rapidly as possible, avoiding exposure to actinic light, oxidising agents, oxidation catalysts (for example, copper and iron) and air.*

The assay is carried out on the methyl or ethyl esters of (all-*Z*)-eicosa-5,8,11,14,17-pentaenoic acid (EPA; 20:5 n-3) and (all-*Z*)-docosa-4,7,10,13,16,19-hexaenoic acid (DHA; 22:6 n-3) in the substance to be examined.

Internal standard. Methyl tricosanoate R.

Test solution (a)

A. Dissolve the mass of sample to be examined according to Table 2.4.29.-1 and about 70.0 mg of the internal standard in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution.

Table 2.4.29.-1.

Approximate sum EPA + DHA (per cent)	Mass of sample to be examined (grams)
30 - 50	0.4 - 0.5
50 - 70	0.3
70 - 90	0.25

Ethyl esters are now ready for analysis. For triglycerides continue as described in step B.

B. Introduce 2.0 ml of the solution obtained in step A into a quartz tube and evaporate the solvent with a gentle current of *nitrogen R*. Add 1.5 ml of a 20 g/l solution of *sodium hydroxide R* in *methanol R*, cover with *nitrogen R*, cap tightly with a polytetrafluoroethylene-lined cap, mix and heat on a water-bath for 7 min. Allow to cool. Add 2 ml of *boron trichloride-methanol solution R*, cover with *nitrogen R*, cap tightly, mix and heat on a water-bath for 30 min. Cool to 40-50 °C, add 1 ml of *trimethylpentane R*, cap and shake vigorously for at least 30 s. Immediately add 5 ml of a *saturated sodium chloride solution R*, cover with *nitrogen R*, cap and shake thoroughly for at least 15 s. Transfer the upper layer to a separate tube. Shake the methanol layer once more with 1 ml of *trimethylpentane R*. Wash the combined trimethylpentane extracts with 2 quantities, each of 1 ml, of *water R* and dry over *anhydrous sodium sulphate R*. Prepare 3 solutions for each sample.

Test solution (b). Dissolve 0.300 g of the sample to be examined in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution. Proceed as described for test solution (a).

Reference solution (a). Dissolve 60.0 mg of *docosahexaenoic acid ethyl ester CRS*, about 70.0 mg of the internal standard and 90.0 mg of *eicosapentaenoic acid ethyl ester CRS* in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution. Proceed as described for test solution (a) step A when analysing ethyl esters. For analysis of triglycerides, continue with step B in the same manner as for test solution (a). Prepare 3 solutions for each sample.

Reference solution (b). Into a 10 ml volumetric flask dissolve 0.3 g of *methyl palmitate R*, 0.3 g of *methyl stearate R*, 0.3 g of *methyl arachidate R* and 0.3 g of *methyl behenate R*, in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution.

Reference solution (c). Into a 10 ml volumetric flask dissolve a sample containing about 55.0 mg of *docosahexaenoic acid methyl ester R* and about 5.0 mg of *tetracos-15-enoic acid methyl ester R* in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution.

Column:

- *material*: fused silica,
- *dimensions*: *l* = at least 25 m, Ø = 0.25 mm,
- *stationary phase*: bonded *macrogol 20 000 R* (film thickness 0.2 µm).

Carrier gas: *hydrogen for chromatography R* or *helium for chromatography R*.

Flow rate: 1 ml/min.

Split ratio: 1:200, alternatively splitless with temperature control (sample solutions need to be diluted 1/200 with a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* before injection).

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 2	170
	2 - 25.7	170 → 240
	25.7 - 28	240
Injection port		250
Detector		270

Detection: flame ionisation.

Injection: 1 µl, twice.

System suitability:

- in the chromatogram obtained with reference solution (b), the area per cent composition increases in the following order: methyl palmitate, methyl stearate, methyl arachidate, methyl behenate; the difference between the percentage area of methyl palmitate and that of methyl behenate is less than 2.0 area per cent units,
- *resolution*: minimum of 1.2 between the peaks due to docosahexaenoic acid methyl ester and to tetracos-15-enoic acid methyl ester in the chromatogram obtained with reference solution (c),
- in the chromatogram obtained with test solution (a), the peaks due to methyl tricosanoate and any heneicosapentaenoic acid methyl ester or ethyl ester (C21:5) present when compared with the chromatogram obtained with test solution (b) are clearly separated (if not, a correction factor has to be used).

Calculate the percentage content of EPA and DHA using the following expression and taking into account the assigned value of the reference substances:

$$A_x \times \frac{A_3}{m_3} \times \frac{m_1}{A_1} \times \frac{m_{x,r}}{A_{x,r}} \times \frac{1}{m_2} \times C \times 100$$

m_1 = mass of the internal standard in test solution (a), in milligrams,

m_2 = mass of the sample to be examined in test solution (a), in milligrams,

m_3 = mass of the internal standard in reference solution (a), in milligrams,

$m_{x,r}$ = mass of *eicosapentaenoic acid ethyl ester CRS* or *docosahexaenoic acid ethyl ester CRS* in reference solution (a), in milligrams,

A_x = area of the peak due to eicosapentaenoic acid ester or docosahexaenoic acid ester in the chromatogram obtained with test solution (a),

$A_{x,r}$ = area of the peak due to eicosapentaenoic acid ester or docosahexaenoic acid ester in the chromatogram obtained with reference solution (a),

A_1 = area of the peak due to the internal standard in the chromatogram obtained with test solution (a),

A_3 = area of the peak due to the internal standard in the chromatogram obtained with reference solution (a),

C = conversion factor between ethyl ester and triglycerides,

C = 1.00 for ethyl esters,

C = 0.954 for EPA,

C = 0.957 for DHA.

TOTAL OMEGA-3 ACIDS

From the assay for EPA and DHA, calculate the percentage content of the total omega-3 acids using the following expression and identifying the peaks from the chromatograms:

$$EPA + DHA + \frac{A_{n-3}\ (EPA + DHA)}{A_{\mathrm{EPA}} + A_{\mathrm{DHA}}}$$

EPA = percentage content of EPA,

DHA = percentage content of DHA,

$A_{\mathrm{n\text{-}3}}$ = sum of the areas of the peaks due to C18:3 n-3, C18:4 n-3, C20:4 n-3, C21:5 n-3 and C22:5 n-3 methyl esters in the chromatogram obtained with test solution (b),

A_{EPA} = area of the peak due to EPA ester in the chromatogram obtained with test solution (b),

A_{DHA} = area of the peak due to DHA ester in the chromatogram obtained with test solution (b).

01/2008:20430

2.4.30. ETHYLENE GLYCOL AND DIETHYLENE GLYCOL IN ETHOXYLATED SUBSTANCES

Ethoxylated substances may contain varied amounts of ethylene glycol and diethylene glycol, as a result of the manufacturing process. The following method may be used for the quantitative determination of these substances, in particular in the case of the following surfactants: macrogolglycerol ricinoleate, macrogolglycerol hydroxystearate, macrogol 15 hydroxystearate, nonoxinol 9 and macrogol cetostearyl ether.

Gas chromatography (*2.2.28*).

Internal standard solution. Dissolve 30.0 mg of *1,2-pentanediol R* in *acetone R* and dilute to 30.0 ml with the same solvent. Dilute 1.0 ml of this solution to 20.0 ml with *acetone R*.

Test solution. Dissolve 0.500 g of the substance to be examined in the internal standard solution and dilute to 10.0 ml with the same solution.

Reference solution (a). Mix 30.0 mg of *ethylene glycol R* with *acetone R* and dilute to 100.0 ml with the same solvent. Dilute 1.0 ml to 10.0 ml with the internal standard solution.

Reference solution (b). Prepare a solution of *diethylene glycol R* with a concentration corresponding to the prescribed limit and using the same solvents as for the preparation of reference solution (a).

Column:

- *material*: fused silica,
- *size*: *l* = 30 m, Ø = 0.53 mm,
- *stationary phase*: *macrogol 20 000 R* (film thickness 1 µm).

Carrier gas: *helium for chromatography R*.

Flow rate: 10 ml/min.

Split ratio: 1:3.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 40	80 → 200
	40 - 45	200 → 230
	45 - 65	230
Injection port		250
Detector		250

Detection: flame ionisation.

Injection: 2 µl.

Relative retention with reference to 1,2-pentanediol (retention time = about 19 min): ethylene glycol = about 0.7; diethylene glycol = about 1.3.

01/2008:20431

2.4.31. NICKEL IN HYDROGENATED VEGETABLE OILS

Atomic absorption spectrometry (*2.2.23, Method I*).

CAUTION: when using closed high-pressure digestion vessels and microwave laboratory ovens, be familiar with the safety and operating instructions given by the manufacturer.

The reagents magnesium nitrate R and ammonium dihydrogen phosphate R must be controlled for nickel before use. The actual nickel content is taken into account in the calculation of the nickel content of the sample.

Test solution. Weigh 0.250 g (*m*) of the substance to be examined into a suitable high-pressure-resistant digestion vessel (fluoropolymer or quartz glass), add 6.0 ml of *nickel-free nitric acid R* and 2.0 ml of *strong hydrogen peroxide solution R*. Prepare a blank solution in the same manner. Place the closed vessels in a laboratory microwave oven and digest with an appropriate programme, e.g. 1000 W for 40 min. Allow the digestion vessels to cool before opening. Add 2.0 ml of *strong hydrogen peroxide solution R* and repeat the digestion step. Allow the digestion vessels to cool before opening. Quantitatively transfer to a 25 ml flask, add 0.5 ml of a 10 g/l solution of *magnesium*

nitrate R and 0.5 ml of a 100 g/l solution of *ammonium dihydrogen phosphate R*, dilute to 25.0 ml with *water for chromatography R* and mix.

Reference solutions. Into 4 volumetric flasks, introduce 25 µl, 50 µl, 75 µl and 100 µl of *nickel standard solution (5 ppm Ni) R*. To each flask, add 0.5 ml of a 10 g/l solution of *magnesium nitrate R*, 0.5 ml of a 100 g/l solution of *ammonium dihydrogen phosphate R* and 6.0 ml of *nickel-free nitric acid R* and dilute to 25.0 ml with *water for chromatography R*. Mix to obtain reference solutions containing respectively 5 ng/ml, 10 ng/ml, 15 ng/ml and 20 ng/ml (ppb) of nickel.

Zero solution. In a volumetric flask, introduce 1.0 ml of a 10 g/l solution of *magnesium nitrate R*, 1.0 ml of a 100 g/l solution of *ammonium dihydrogen phosphate R* and 12.0 ml of *nickel-free nitric acid R*. Dilute to 50.0 ml with *water for chromatography R* and mix.

Method. Determine the absorbance of each solution at 232.0 nm using a suitable graphite furnace atomic absorption spectrometer equipped with a background compensation system, a pyrolytically-coated tube, and a nickel hollow-cathode lamp. Maintain the drying temperature of the furnace at 120 °C for 35 s after a 5 s ramp, the ashing temperature at 1100 °C for 10 s after a 30 s ramp, the cooling temperature at 800 °C for 5 s after a 5 s decrease, and the atomisation temperature at 2600 °C for 7 s. Use the zero solution to set the instrument to zero. Using the calibration curve, determine the concentrations of the test solution and the blank solution from the corresponding absorptions. If necessary, dilute with the zero solution to obtain a reading within the calibrated absorbance range.

Calculate the content of Ni in micrograms per gram (ppm) using the following expression:

$$\frac{c \times f}{m \times 40}$$

c = measured concentration of Ni, in nanograms per millilitre;

f = dilution factor of the test solution;

m = mass of the substance to be examined, in grams.

01/2008:20432

2.4.32. TOTAL CHOLESTEROL IN OILS RICH IN OMEGA-3 ACIDS

This method may be used for the quantitative determination of the sum of free and esterified cholesterol in products of fish oils rich in omega-3 acids (as ethyl esters or triglycerides).

Gas chromatography (*2.2.28*).

Internal standard stock solution. Dissolve 0.15 g of *(5α)-cholestane R* in *heptane R* and dilute to 50.0 ml with the same solvent.

Internal standard working solution. Prepare the solution immediately before use. Dilute 1.0 ml of the internal standard stock solution to 10.0 ml with *heptane R*.

Cholesterol stock solution. Dissolve 30.0 mg of *cholesterol R* in *heptane R* and dilute to 10.0 ml with the same solvent. The solution is dispensed into gas chromatography vials and may be stored in a deep-freezer for up to 6 months.

Cholesterol working solution. Prepare the solution immediately before use. Dilute 1.0 ml of the cholesterol stock solution to 10.0 ml with *heptane R*.

α-Tocopherol solution. Dilute 15.0 mg of *α-tocopherol CRS* to 10.0 ml with *heptane R*.

Test solution. Weigh 0.100 g of the substance to be examined into a 15 ml quartz tube. Add 1.0 ml of the internal standard stock/working solution, depending on the expected cholesterol content in the oil (see Table 2.4.32.-1).

Evaporate to dryness on a heating block at 50 °C under a gentle stream of nitrogen, while mixing. Add 0.5 ml of a 50 per cent solution of *potassium hydroxide R* and 3.0 ml of *ethanol (96 per cent) R*. Fill the tube with *nitrogen R* and cap. Further heat on the heating block at 100 °C for 1 h with stirring. Cool for about 10 min and add 6 ml of *distilled water R*. Extract with 4 quantities, each of 2.5 ml, of *ether R*, mixing each time for 1 min using a vortex mixer. Transfer the ether phase to a large centrifuge tube or a separating funnel and wash the combined extracts with 5 ml of *distilled water R*, mixing carefully a fixed number of times, e.g. 60 times. Discard the aqueous phase, add 5 ml of a 3 per cent solution of *potassium hydroxide R* to the ether phase and mix carefully 20 times. Discard the aqueous phase, add another 5 ml of *distilled water R* and mix carefully a further 20 times. Transfer the ether phase into a small centrifuge tube, avoiding any transfer of water. If an emulsion forms during the process, add a small amount of *sodium chloride R* to get a separation of the phases.

Evaporate to dryness under a gentle stream of nitrogen with careful heating. Dissolve the residue in 600 µl of *ethyl acetate R*.

Depending on the expected cholesterol content in the oil, the solution is further diluted as follows:

– content less than 3 mg/g: dilute 200 µl of the solution to 2.0 ml with *ethyl acetate R*;

– content greater than or equal to 3 mg/g: dilute 20 µl of the solution to 2.0 ml with *ethyl acetate R*.

Reference solution (a). Transfer 1.0 ml of the internal standard stock/working solution and 1.0 ml of the cholesterol stock/working solution, depending on the expected cholesterol content in the oil (see Table 2.4.32.-1), to a 15 ml quartz tube and continue as described for the test solution, starting with “Evaporate to dryness on a heating block...”.

Reference solution (b). Mix 1.0 ml of the cholesterol stock solution and 2.0 ml of the α-tocopherol solution in a suitable flask. Evaporate to dryness under a gentle stream of nitrogen with careful heating. Dissolve the residue in *ethyl acetate R* and dilute to 50.0 ml with the same solvent. The solution may be stored in a deep-freezer for up to 6 months.

Table 2.4.32.-1. – *Preparation of the test and reference solutions*

	Test solution		Reference solution (a)		Reference solution (b)
	less than 3 mg/g	greater than or equal to 3 mg/g	less than 3 mg/g	greater than or equal to 3 mg/g	
Internal standard stock solution	–	+	–	+	–
Internal standard working solution	+	–	+	–	–
Cholesterol stock solution	–	–	–	+	+
Cholesterol working solution	–	–	+	–	–
α-Tocopherol solution	–	–	–	–	+

Column:

– *size*: *l* = 30 m, Ø = 0.25 mm (film thickness 0.25 µm);

– *stationary phase*: *poly(dimethyl)(diphenyl)siloxane R.*

Carrier gas: *helium for chromatography R.*

Flow rate: 1.3 ml/min.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 1	170
	1 - 38	170 → 320
	38 - 40	320
Injection port		320
Detector		300

Detection: flame ionisation.

Injection: 1 µl.

System suitability: reference solution (b):

– *resolution*: minimum 1.2 between the peaks due to cholesterol and α-tocopherol.

Calculate the content of total cholesterol, expressed as milligrams of cholesterol per gram of oil, using the following expression:

$$\frac{A_1 \times m_2 \times F}{A_2 \times m_1 \times R}$$

A_1 = area of the peak due to cholesterol in the chromatogram obtained with the test solution;

A_2 = area of the peak due to (5α)-cholestane in the chromatogram obtained with the test solution;

m_1 = mass of the substance to be examined in the test solution, in grams;

m_2 = mass of (5α)-cholestane in the internal standard stock solution, in grams;

F = 20 for oils with an expected cholesterol content greater than or equal to 3 mg/g; 2 for oils with an expected cholesterol content less than 3 mg/g;

R = response factor.

Calculate the response factor R using the following expression:

$$\frac{A_3 \times m_2}{A_4 \times m_3 \times 5}$$

A_3 = area of the peak due to cholesterol in the chromatogram obtained with reference solution (a);

A_4 = area of the peak due to (5α)-cholestane in the chromatogram obtained with reference solution (a);

m_3 = mass of cholesterol in the cholesterol stock solution, in grams.

2.5. ASSAYS

01/2008:20501

2.5.1. ACID VALUE

The acid value I_A is the number that expresses, in milligrams the quantity of potassium hydroxide required to neutralise the free acids present in 1 g of the substance.

Dissolve 10.00 g of the substance to be examined, or the quantity prescribed, (*m* g), in 50 ml of a mixture of equal volumes of *ethanol (96 per cent) R* and *light petroleum R3*, previously neutralised with *0.1 M potassium hydroxide* or *0.1 M sodium hydroxide*, unless otherwise specified, using 0.5 ml of *phenolphthalein solution R1* as indicator. If necessary, heat to about 90 °C to dissolve the substance to be examined. When the substance to be examined has dissolved, titrate with *0.1 M potassium hydroxide* or *0.1 M sodium hydroxide* until the pink colour persists for at least 15 s (*n* ml of titrant). When heating has been applied to aid dissolution, maintain the temperature at about 90 °C during the titration.

$$I_A = \frac{5.610n}{m}$$

01/2008:20502

2.5.2. ESTER VALUE

The ester value I_E is the number that expresses in milligrams the quantity of potassium hydroxide required to saponify the esters present in 1 g of the substance. It is calculated from the saponification value I_S and the acid value I_A:

$$I_E = I_S - I_A$$

01/2008:20503

2.5.3. HYDROXYL VALUE

The hydroxyl value I_{OH} is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the acid combined by acylation in 1 g of the substance.

METHOD A

Introduce the quantity of the substance to be examined shown in Table 2.5.3.-1 (*m* g) into a 150 ml acetylation flask fitted with an air condenser, unless another quantity is prescribed in the monograph. Add the quantity of *acetic anhydride solution R1* stated in Table 2.5.3.-1 and attach the air condenser.

Table 2.5.3.-1

Presumed value I_{OH}	Quantity of sample (g)	Volume of acetylating reagent (ml)
10 - 100	2.0	5.0
100 - 150	1.5	5.0
150 - 200	1.0	5.0
200 - 250	0.75	5.0
250 - 300	0.60 or 1.20	5.0 or 10.0
300 - 350	1.0	10.0
350 - 700	0.75	15.0
700 - 950	0.5	15.0

Heat the flask in a water-bath for 1 h keeping the level of the water about 2.5 cm above the level of the liquid in the flask. Withdraw the flask and allow to cool. Add 5 ml of *water R* through the upper end of the condenser. If a cloudiness appears add sufficient *pyridine R* to clear it, noting the volume added. Shake the flask and replace in the water-bath for 10 min. Withdraw the flask and allow to cool. Rinse the condenser and the walls of the flask with 5 ml of *alcohol R*, previously neutralised to *phenolphthalein solution R1*. Titrate with *0.5 M alcoholic potassium hydroxide* using 0.2 ml of *phenolphthalein solution R1* as indicator (n_1 ml of *0.5 M alcoholic potassium hydroxide*). Carry out a blank test under the same conditions (n_2 ml of *0.5 M alcoholic potassium hydroxide*).

$$I_{OH} = \frac{28.05\,(n_2 - n_1)}{m} + I_A$$

METHOD B

Introduce the prescribed quantity of the substance to be examined (*m* g) into a perfectly dry 5 ml conical flask fitted with a ground-glass or suitable plastic stopper and add 2.0 ml of *propionic anhydride reagent R*. Close the flask and shake gently to dissolve the substance. Allow to stand for 2 h unless otherwise prescribed. Remove the stopper and transfer the flask and its contents into a wide-mouthed 500 ml conical flask containing 25.0 ml of a 9 g/l solution of *aniline R* in *cyclohexane R* and 30 ml of *glacial acetic acid R*. Swirl the contents of the flask, allow to stand for 5 min, add 0.05 ml of *crystal violet solution R* and titrate with *0.1 M perchloric acid* until an emerald-green colour is obtained (n_1 ml of *0.1 M perchloric acid*). Carry out a blank test under the same conditions (n_2 ml of *0.1 M perchloric acid*).

$$I_{OH} = \frac{5.610\,(n_1 - n_2)}{m}$$

To take account of any water present, determine this (*y* per cent) by the semi-micro determination of water (*2.5.12*). The hydroxyl value is then given by the equation:

$$I_{OH} = (\text{hydroxyl value as determined}) - 31.1y$$

01/2008:20504

2.5.4. IODINE VALUE

The iodine value I_I is the number that expresses in grams the quantity of halogen, calculated as iodine, that can be fixed in the prescribed conditions by 100 g of the substance.

When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.

METHOD A

Unless otherwise prescribed, use the following quantities (Table 2.5.4.-1) for the determination.

Table 2.5.4.-1

Presumed value I_I	Quantity of sample (g)
less than 20	1.0
20 - 60	0.5 - 0.25
60 - 100	0.25 - 0.15
more than 100	0.15 - 0.10

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 ml flask fitted with a ground-glass stopper and previously dried or rinsed with *glacial acetic*

acid R, and dissolve it in 15 ml of *chloroform R* unless otherwise prescribed. Add very slowly 25.0 ml of *iodine bromide solution R*. Close the flask and keep it in the dark for 30 min unless otherwise prescribed, shaking frequently. Add 10 ml of a 100 g/l solution of *potassium iodide R* and 100 ml of *water R*. Titrate with *0.1 M sodium thiosulphate*, shaking vigorously until the yellow colour is almost discharged. Add 5 ml of *starch solution R* and continue the titration adding the *0.1 M sodium thiosulphate* dropwise until the colour is discharged (n_1 ml of *0.1 M sodium thiosulphate*). Carry out a blank test under the same conditions (n_2 ml of *0.1 M sodium thiosulphate*).

$$I_I = \frac{1.269\ (n_2 - n_1)}{m}$$

METHOD B

Unless otherwise prescribed, use the following quantities (Table 2.5.4.-2) for the determination.

Table 2.5.4.-2

Presumed value I_I	Mass (g) (corresponding to an excess of 150 per cent ICl)	Mass (g) (corresponding to an excess of 100 per cent ICl)	Iodine chloride solution (ml)
<3	10	10	25
3	8.4613	10.5760	25
5	5.0770	6.3460	25
10	2.5384	3.1730	20
20	0.8461	1.5865	20
40	0.6346	0.7935	20
60	0.4321	0.5288	20
80	0.3173	0.3966	20
100	0.2538	0.3173	20
120	0.2115	0.2644	20
140	0.1813	0.2266	20
160	0.1587	0.1983	20
180	0.1410	0.1762	20
200	0.1269	0.1586	20

The mass of the sample is such that there will be an excess of *iodine chloride solution R* of 50 per cent to 60 per cent of the amount added, i.e. 100 per cent to 150 per cent of the amount absorbed.

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 ml flask fitted with a ground-glass stopper and previously rinsed with *glacial acetic acid R* or dried, and dissolve it in 15 ml of a mixture of equal volumes of *cyclohexane R* and *glacial acetic acid R*, unless otherwise prescribed. If necessary, melt the substance before dissolution (melting point greater than 50 °C). Add very slowly the volume of *iodine chloride solution R* stated in Table 2.5.4.-2. Close the flask and keep it in the dark for 30 min, unless otherwise prescribed, shaking frequently. Add 10 ml of a 100 g/l solution of *potassium iodide R* and 100 ml of *water R*. Titrate with *0.1 M sodium thiosulphate*, shaking vigorously until the yellow colour is almost discharged. Add 5 ml of *starch solution R* and continue the titration adding the *0.1 M sodium thiosulphate* dropwise until the colour is discharged (n_1 ml of *0.1 M sodium thiosulphate*). Carry out a blank test under the same conditions (n_2 ml of *0.1 M sodium thiosulphate*).

$$I_I = \frac{1.269\ (n_2 - n_1)}{m}$$

01/2008:20505

2.5.5. PEROXIDE VALUE

The peroxide value I_P is the number that expresses in milliequivalents of active oxygen the quantity of peroxide contained in 1000 g of the substance, as determined by the methods described below.

When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.

METHOD A

Place 5.00 g of the substance to be examined (*m* g) in a 250 ml conical flask fitted with a ground-glass stopper. Add 30 ml of a mixture of 2 volumes of *chloroform R* and 3 volumes of *glacial acetic acid R*. Shake to dissolve the substance and add 0.5 ml of *saturated potassium iodide solution R*. Shake for exactly 1 min then add 30 ml of *water R*. Titrate with *0.01 M sodium thiosulphate*, adding the titrant slowly with continuous vigorous shaking, until the yellow colour is almost discharged. Add 5 ml of *starch solution R* and continue the titration, shaking vigorously, until the colour is discharged (n_1 ml of *0.01 M sodium thiosulphate*). Carry out a blank test under the same conditions (n_2 ml of *0.01 M sodium thiosulphate*). The volume of *0.01 M sodium thiosulphate* used in the blank titration must not exceed 0.1 ml.

$$I_P = \frac{10\,(n_1 - n_2)}{m}$$

METHOD B

Carry out the operations avoiding exposure to actinic light.

Place 50 ml of a mixture of 2 volumes of *trimethylpentane R* and 3 volumes of *glacial acetic acid R* in a conical flask and replace the stopper. Swirl the flask until the substance to be examined (*m* g; see Table 2.5.5.-1) has dissolved. Using a suitable volumetric pipette, add 0.5 ml of *saturated potassium iodide solution R* and replace the stopper. Allow the solution to stand for 60 ± 1 s, thoroughly shaking the solution continuously, then add 30 ml of *water R*.

Table 2.5.5.-1

Expected peroxide value I_p	Mass of substance to be examined (g)
0 to 12	2.00 to 5.00
12 to 20	1.20 to 2.00
20 to 30	0.80 to 1.20
30 to 50	0.500 to 0.800
50 to 90	0.300 to 0.500

Titrate the solution with *0.01 M sodium thiosulphate* (V_1 ml), adding it gradually and with constant, vigorous shaking, until the yellow iodine colour has almost disappeared. Add about 0.5 ml of *starch solution R1* and continue the titration, with constant shaking especially near the end-point, to liberate all of the iodine from the solvent layer. Add the sodium thiosulphate solution dropwise until the blue colour just disappears.

Depending on the volume of *0.01 M sodium thiosulphate* used, it may be necessary to titrate with *0.1 M sodium thiosulphate*.

NOTE: there is a 15 s to 30 s delay in neutralising the starch indicator for peroxide values of 70 and greater, due to the tendency of trimethylpentane to float on the surface of the aqueous medium and the time necessary to adequately mix the solvent and the aqueous titrant, thus liberating the last traces of iodine. It is recommended to use *0.1 M sodium thiosulphate* for peroxide values greater than 150. A small amount (0.5 per cent to 1.0 per cent (*m/m*)) of high HLB emulsifier (for example polysorbate 60) may be added to the mixture to retard the phase separation and decrease the time lag in the liberation of iodine.

Carry out a blank determination (V_0 ml). If the result of the blank determination exceeds 0.1 ml of titration reagent, replace the impure reagents and repeat the determination.

$$I_p = \frac{1000\,(V_1 - V_0)\,c}{m}$$

c = concentration of the sodium thiosulphate solution in moles, per litre.

01/2008:20506

2.5.6. SAPONIFICATION VALUE

The saponification value I_S is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the free acids and to saponify the esters present in 1 g of the substance.

Unless otherwise prescribed, use the quantities indicated in Table 2.5.6.-1 for the determination.

Table 2.5.6.-1

Presumed value I_S	Quantity of sample (g)
<3	20
3 to 10	12 to 15
10 to 40	8 to 12
40 to 60	5 to 8
60 to 100	3 to 5
100 to 200	2.5 to 3
200 to 300	1 to 2
300 to 400	0.5 to 1

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 ml borosilicate glass flask fitted with a reflux condenser. Add 25.0 ml of *0.5 M alcoholic potassium hydroxide* and a few glass beads. Attach the condenser and heat under reflux for 30 min, unless otherwise prescribed. Add 1 ml of *phenolphthalein solution R1* and titrate immediately (while still hot) with *0.5 M hydrochloric acid* (n_1 ml of *0.5 M hydrochloric acid*). Carry out a blank test under the same conditions (n_2 ml of *0.5 M hydrochloric acid*).

$$I_S = \frac{28.05\,(n_2 - n_1)}{m}$$

01/2008:20507

2.5.7. UNSAPONIFIABLE MATTER

The term “unsaponifiable matter” is applied to the substances non-volatile at 100-105 °C obtained by extraction with an organic solvent from the substance to be examined after it has been saponified. The result is calculated as per cent *m/m*.

Use ungreased ground-glass glassware.

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 ml flask fitted with a reflux condenser. Add 50 ml of *2 M alcoholic potassium hydroxide R* and heat on a water-bath for 1 h, swirling frequently. Cool to a temperature below 25 °C and transfer the contents of the flask to a separating funnel with the aid of 100 ml of *water R*. Shake the liquid carefully with 3 quantities, each of 100 ml, of *peroxide-free ether R*. Combine the ether layers in another separating funnel containing 40 ml of *water R*, shake gently for a few minutes, allow to separate and reject the aqueous phase. Wash the ether phase with 2 quantities, each of 40 ml, of *water R* then wash successively with 40 ml of a 30 g/l solution of *potassium hydroxide R* and 40 ml of *water R*; repeat this procedure 3 times. Wash the ether phase several times, each with 40 ml of *water R*, until the aqueous phase is no longer alkaline to phenolphthalein. Transfer the ether phase to a tared flask, washing the separating funnel with *peroxide-free ether R*.

Distil off the ether with suitable precautions and add 6 ml of *acetone R* to the residue. Carefully remove the solvent in a current of air. Dry to constant mass at 100-105 °C. Allow to cool in a desiccator and weigh (*a* g).

$$\text{Unsaponifiable matter} = \frac{100a}{m} \text{ per cent}$$

Dissolve the residue in 20 ml of *alcohol R*, previously neutralised to *phenolphthalein solution R* and titrate with *0.1 M ethanolic sodium hydroxide*. If the volume of *0.1 M ethanolic sodium hydroxide* used is greater than 0.2 ml, the separation of the layers has been incomplete; the residue weighed cannot be considered as “unsaponifiable matter”. In case of doubt, the test must be repeated.

01/2008:20508

2.5.8. DETERMINATION OF PRIMARY AROMATIC AMINO-NITROGEN

Dissolve the prescribed quantity of the substance to be examined in 50 ml of *dilute hydrochloric acid R* or in another prescribed solvent and add 3 g of *potassium bromide R*. Cool in ice-water and titrate by slowly adding *0.1 M sodium nitrite* with constant stirring.

Determine the end-point electrometrically or by the use of the prescribed indicator.

01/2008:20509

2.5.9. DETERMINATION OF NITROGEN BY SULPHURIC ACID DIGESTION

SEMI-MICRO METHOD

Place a quantity of the substance to be examined (*m* g) containing about 2 mg of nitrogen in a combustion flask, add 4 g of a powdered mixture of 100 g of *dipotassium sulphate R*, 5 g of *copper sulphate R* and 2.5 g of *selenium R*,

and three glass beads. Wash any adhering particles from the neck into the flask with 5 ml of *sulphuric acid R*, allowing it to run down the sides of the flask, and mix the contents by rotation. Close the mouth of the flask loosely, for example by means of a glass bulb with a short stem, to avoid excessive loss of sulphuric acid. Heat gradually at first, then increase the temperature until there is vigorous boiling with condensation of sulphuric acid in the neck of the flask; precautions should be taken to prevent the upper part of the flask from becoming overheated. Continue the heating for 30 min, unless otherwise prescribed. Cool, dissolve the solid material by cautiously adding to the mixture 25 ml of *water R*, cool again and place in a steam-distillation apparatus. Add 30 ml of *strong sodium hydroxide solution R* and distil immediately by passing steam through the mixture. Collect about 40 ml of distillate in 20.0 ml of *0.01 M hydrochloric acid* and enough *water R* to cover the tip of the condenser. Towards the end of the distillation, lower the receiver so that the tip of the condenser is above the surface of the acid. Take precautions to prevent any water on the outer surface of the condenser from reaching the contents of the receiver. Titrate the distillate with *0.01 M sodium hydroxide*, using *methyl red mixed solution R* as indicator (n_1 ml of *0.01 M sodium hydroxide*).

Repeat the test using about 50 mg of *glucose R* in place of the substance to be examined (n_2 ml of *0.01 M sodium hydroxide*).

$$\text{Content of nitrogen} = \frac{0.01401\,(n_2 - n_1)}{m} \text{ per cent}$$

01/2008:20510

2.5.10. OXYGEN-FLASK METHOD

Unless otherwise prescribed the combustion flask is a conical flask of at least 500 ml capacity of borosilicate glass with a ground-glass stopper fitted with a suitable carrier for the sample, for example in platinum or platinum-iridium.

Finely grind the substance to be examined, place the prescribed quantity in the centre of a piece of filter paper measuring about 30 mm by 40 mm provided with a small strip about 10 mm wide and 30 mm long. If paper impregnated with lithium carbonate is prescribed, moisten the centre of the paper with a saturated solution of *lithium carbonate R* and dry in an oven before use. Envelop the substance to be examined in the paper and place it in the sample carrier. Introduce into the flask *water R* or the prescribed solution designed to absorb the combustion products, displace the air with oxygen by means of a tube having its end just above the liquid, moisten the neck of the flask with *water R* and close with its stopper. Ignite the paper strip by suitable means with the usual precautions. Keep the flask firmly closed during the combustion. Shake the flask vigorously to completely dissolve the combustion products. Cool and after about 5 min, unless otherwise prescribed, carefully unstopper the flask. Wash the ground parts and the walls of the flask, as well as the sample carrier, with *water R*. Combine the combustion products and the washings and proceed as prescribed in the monograph.

01/2008:20511

2.5.11. COMPLEXOMETRIC TITRATIONS

ALUMINIUM

Introduce 20.0 ml of the prescribed solution into a 500 ml conical flask, add 25.0 ml of *0.1 M sodium edetate* and 10 ml of a mixture of equal volumes of a 155 g/l solution of *ammonium acetate R* and *dilute acetic acid R*. Boil for 2 min, then cool. Add 50 ml of *ethanol R* and 3 ml of a freshly prepared 0.25 g/l solution of *dithizone R* in *ethanol R*. Titrate the excess of sodium edetate with *0.1 M zinc sulphate* until the colour changes from greenish-blue to reddish-violet.

1 ml of *0.1 M sodium edetate* is equivalent to 2.698 mg of Al.

BISMUTH

Introduce the prescribed solution into a 500 ml conical flask. Dilute to 250 ml with *water R* and then, unless otherwise prescribed, add dropwise, with shaking, *concentrated ammonia R* until the mixture becomes cloudy. Add 0.5 ml of *nitric acid R*. Heat to about 70 °C until the cloudiness disappears completely. Add about 50 mg of *xylenol orange triturate R* and titrate with *0.1 M sodium edetate* until the colour changes from pinkish-violet to yellow.

1 ml of *0.1 M sodium edetate* is equivalent to 20.90 mg of Bi.

CALCIUM

Introduce the prescribed solution into a 500 ml conical flask, and dilute to 300 ml with *water R*. Add 6.0 ml of *strong sodium hydroxide solution R* and about 15 mg of *calconecarboxylic acid triturate R*. Titrate with *0.1 M sodium edetate* until the colour changes from violet to full blue.

1 ml of *0.1 M sodium edetate* is equivalent to 4.008 mg of Ca.

MAGNESIUM

Introduce the prescribed solution into a 500 ml conical flask and dilute to 300 ml with *water R*. Add 10 ml of *ammonium chloride buffer solution pH 10.0 R* and about 50 mg of *mordant black 11 triturate R*. Heat to about 40 °C then titrate at this temperature with *0.1 M sodium edetate* until the colour changes from violet to full blue.

1 ml of *0.1 M sodium edetate* is equivalent to 2.431 mg of Mg.

LEAD

Introduce the prescribed solution into a 500 ml conical flask and dilute to 200 ml with *water R*. Add about 50 mg of *xylenol orange triturate R* and *hexamethylenetetramine R* until the solution becomes violet-pink. Titrate with *0.1 M sodium edetate* until the violet-pink colour changes to yellow.

1 ml of *0.1 M sodium edetate* is equivalent to 20.72 mg of Pb.

ZINC

Introduce the prescribed solution into a 500 ml conical flask and dilute to 200 ml with *water R*. Add about 50 mg of *xylenol orange triturate R* and *hexamethylenetetramine R* until the solution becomes violet-pink. Add 2 g of *hexamethylenetetramine R* in excess. Titrate with *0.1 M sodium edetate* until the violet-pink colour changes to yellow.

1 ml of *0.1 M sodium edetate* is equivalent to 6.54 mg of Zn.

01/2008:20512 corrected 6.0

2.5.12. WATER: SEMI-MICRO DETERMINATION

The semi-micro determination of water is based upon the quantitative reaction of water with sulphur dioxide and iodine in a suitable anhydrous medium in the presence of a base with sufficient buffering capacity.

Apparatus

The apparatus consists of a titration vessel with:

- 2 identical platinum electrodes;
- tight inlets for introduction of solvent and titrant;
- an inlet for introduction of air via a desiccant;
- a sample inlet fitted with a stopper or, for liquids, a septum.

Inlet systems for introduction of dry nitrogen or for aspiration of solvents may also be fitted.

The titration is carried out according to the instrument supplier's instructions. Care is taken throughout the determination to avoid exposure of reagents and solvents to atmospheric moisture. The end-point is determined using 2 identical indicator electrodes connected to an electrical source that maintains between the electrodes either a constant current or a constant voltage. Where direct titration is used (method A), addition of titrant causes either a decrease in voltage where constant current is maintained or an increase in current where constant voltage is maintained, until the end-point is reached. Instruments with automatic end-point detection are commonly used.

Standardisation. To the titration vessel, add *methanol R*, dried if necessary, or the solvent recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce a suitable amount of water in an appropriate form (*water R* or a certified reference material) and carry out the titration, stirring for the necessary time. The water equivalent is not less than 80 per cent of that indicated by the supplier. Standardise the titrant before the first use and at suitable intervals thereafter.

Unless otherwise prescribed, use Method A.

Method A. Introduce into the titration vessel *methanol R*, or the solvent indicated in the monograph or recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce the substance to be examined rapidly and carry out the titration, stirring for the necessary extraction time.

Method B. Introduce into the titration vessel *methanol R*, or the solvent indicated in the monograph or recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce the substance to be examined rapidly and in a suitable state of division. Add an accurately measured volume of the titrant, sufficient to give an excess of about 1 ml or the prescribed volume. Allow to stand protected from light for 1 min or the prescribed time, with stirring. Titrate the excess of reagent using *methanol R* or the prescribed solvent, containing an accurately known quantity of water.

Suitability. The accuracy of the determination with the chosen titrant must be verified for each substance to be examined. The following procedure, given as an example, is suitable for samples containing 2.5-25 mg of water.

The water content of the substance to be examined is determined using the reagent/solvent system chosen. Thereafter, sequential known amounts of *water R* are added in an appropriate form (at least 5 additions) and the cumulative water content determined after each addition. Calculate the percentage recovery (r) at each point using the following expression:

$$r = 100\frac{W_2}{W_1}$$

W_1 = amount of water added, in milligrams;

W_2 = amount of water found, in milligrams.

Calculate the regression line of the cumulative water determined against the water added. Calculate the slope (b), the intercept with the y-axis (a) and the intercept of the extrapolated calibration line with the x-axis (d).

Calculate the percentage mean recovery ($\overline{r}$). Calculate the percentage errors (e_1 and e_2) using the following expressions:

$$e_1 = 100\frac{a - M}{M}$$

$$e_2 = 100\frac{|d| - M}{M}$$

a = the y-axis intercept, in milligrams of water;

d = the x-axis intercept, in milligrams of water;

M = water content of the substance, in milligrams of water.

The reagent/solvent system is considered to be acceptable if:

- $|e_1|$ and $|e_2|$ are not greater than 2.5 per cent;
- b is between 0.975 and 1.025 (deviation ± 2.5 per cent);
- $\overline{r}$ is between 97.5 per cent and 102.5 per cent.

01/2008:20513

2.5.13. ALUMINIUM IN ADSORBED VACCINES

Homogenise the preparation to be examined and transfer a suitable quantity, presumed to contain 5 mg to 6 mg of aluminium, to a 50 ml combustion flask. Add 1 ml of *sulphuric acid R*, 0.1 ml of *nitric acid R* and some glass beads. Heat the solution until thick, white fumes are evolved. If there is charring at this stage add a few more drops of *nitric acid R* and continue boiling until the colour disappears. Allow to cool for a few minutes, carefully add 10 ml of *water R* and boil until a clear solution is obtained. Allow to cool, add 0.05 ml of *methyl orange solution R* and neutralise with *strong sodium hydroxide solution R* (6.5 ml to 7 ml). If a precipitate forms dissolve it by adding, dropwise, sufficient *dilute sulphuric acid R*. Transfer the solution to a 250 ml conical flask, rinsing the combustion flask with 25 ml of *water R*. Add 25.0 ml of *0.02 M sodium edetate*, 10 ml of *acetate buffer solution pH 4.4 R* and a few glass beads and boil gently for 3 min. Add 0.1 ml of *pyridylazonaphthol solution R* and titrate the hot solution with *0.02 M copper sulphate* until the colour changes to purplish-brown. Carry out a blank titration omitting the vaccine.

1 ml of *0.02 M sodium edetate* is equivalent to 0.5396 mg of Al.

01/2008:20514

2.5.14. CALCIUM IN ADSORBED VACCINES

All solutions used for this test must be prepared using water R.

Determine the calcium by atomic emission spectrometry (*2.2.22, Method I*). Homogenise the preparation to be examined. To 1.0 ml add 0.2 ml of *dilute hydrochloric acid R* and dilute to 3.0 ml with *water R*. Measure the absorbance at 620 nm.

01/2008:20515

2.5.15. PHENOL IN IMMUNOSERA AND VACCINES

Homogenise the preparation to be examined. Dilute an appropriate volume with *water R* so as to obtain a solution presumed to contain 15 µg of phenol per millilitre. Prepare a series of reference solutions with *phenol R* containing 5 µg, 10 µg, 15 µg, 20 µg and 30 µg of phenol per millilitre respectively. To 5 ml of the solution to be examined and to 5 ml of each of the reference solutions respectively, add 5 ml of *buffer solution pH 9.0 R*, 5 ml of *aminopyrazolone solution R* and 5 ml of *potassium ferricyanide solution R*. Allow to stand for 10 min and measure the intensity of colour at 546 nm.

Plot the calibration curve and calculate the phenol content of the preparation to be examined.

01/2008:20516

2.5.16. PROTEIN IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Place 1 ml of the solution in a glass tube and add 0.15 ml of a 400 g/l solution of *trichloroacetic acid R*. Shake, allow to stand for 15 min, centrifuge for 10 min at 5000 r/min and discard the supernatant. Add 0.4 ml of *0.1 M sodium hydroxide* to the centrifugation residue.

Reference solutions. Dissolve 0.100 g of *bovine albumin R* in 100 ml of *0.1 M sodium hydroxide* (stock solution containing 1 g of protein per litre). Dilute 1 ml of the stock solution to 20 ml with *0.1 M sodium hydroxide* (working dilution 1: 50 mg of protein per litre). Dilute 1 ml of the stock solution to 4 ml with *0.1 M sodium hydroxide* (working dilution 2: 250 mg of protein per litre). Place in 6 glass tubes 0.10 ml, 0.20 ml and 0.40 ml of working dilution 1 and 0.15 ml, 0.20 ml and 0.25 ml of working dilution 2. Make up the volume in each tube to 0.40 ml using *0.1 M sodium hydroxide*.

Prepare a blank using 0.40 ml of *0.1 M sodium hydroxide*.

Add 2 ml of *cupri-tartaric solution R3* to each tube, shake and allow to stand for 10 min. Add to each tube 0.2 ml of a mixture of equal volumes of *phosphomolybdotungstic reagent R* and *water R*, prepared immediately before use. Stopper the tubes, mix by inverting and allow to stand in the dark for 30 min. The blue colour is stable for 60 min. If necessary, centrifuge to obtain clear solutions.

Measure the absorbance (*2.2.25*) of each solution at 760 nm using the blank as the compensation liquid. Draw a calibration curve from the absorbances of the 6 reference solutions and the corresponding protein contents and read from the curve the content of protein in the test solution.

01/2008:20517

2.5.17. NUCLEIC ACIDS IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*.

Dilute the test solution if necessary to obtain an absorbance value suitable for the instrument used. Measure the absorbance (*2.2.25*) at 260 nm using *water R* as the compensation liquid.

The absorbance of a 1 g/l solution of nucleic acid at 260 nm is 20.

01/2008:20518

2.5.18. PHOSPHORUS IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volume used in the test (1 ml) contains about 6 µg of phosphorus. Transfer 1.0 ml of the solution to a 10 ml ignition tube.

Reference solutions. Dissolve 0.2194 g of *potassium dihydrogen phosphate R* in 500 ml of *water R* to give a solution containing the equivalent of 0.1 mg of phosphorus per millilitre. Dilute 5.0 ml of the solution to 100.0 ml with *water R*. Introduce 0.5 ml, 1.0 ml and 2.0 ml of the dilute solution into 3 ignition tubes.

Prepare a blank solution using 2.0 ml of *water R* in an ignition tube.

To all the tubes add 0.2 ml of *sulphuric acid R* and heat in an oil bath at 120 °C for 1 h and then at 160 °C until white fumes appear (about 1 h). Add 0.1 ml of *perchloric acid R* and heat at 160 °C until the solution is decolorised (about 90 min). Cool and add to each tube 4 ml of *water R* and 4 ml of *ammonium molybdate reagent R*. Heat in a water-bath at 37 °C for 90 min and cool. Adjust the volume to 10.0 ml with *water R*. The blue colour is stable for several hours.

Measure the absorbance (*2.2.25*) of each solution at 820 nm using the blank solution as the compensation liquid. Draw a calibration curve with the absorbances of the 3 reference solutions as a function of the quantity of phosphorus in the solutions and read from the curve the quantity of phosphorus in the test solution.

01/2008:20519

2.5.19. *O*-ACETYL IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 30 µg to 600 µg of acetylcholine chloride (*O*-acetyl). Introduce 0.3 ml, 0.5 ml and 1.0 ml in duplicate into 6 tubes (3 reaction solutions and 3 correction solutions).

Reference solutions. Dissolve 0.150 g of *acetylcholine chloride R* in 10 ml of *water R* (stock solution containing 15 g of acetylcholine chloride per litre). Immediately before use, dilute 1 ml of the stock solution to 50 ml with *water R* (working dilution 1: 300 µg of acetylcholine chloride per millilitre). Immediately before use, dilute 1 ml of the stock solution to 25 ml with *water R* (working dilution 2: 600 µg of acetylcholine chloride per millilitre). Introduce 0.1 ml and 0.4 ml of working dilution 1 in duplicate (reaction and correction solutions) in 4 tubes and 0.6 ml and 1.0 ml of working dilution 2 in duplicate (reaction and correction solutions) in another 4 tubes.

Prepare a blank using 1 ml of *water R*.

Make up the volume in each tube to 1 ml with *water R*. Add 1.0 ml of *4 M hydrochloric acid* to each of the correction tubes and to the blank. Add 2.0 ml of *alkaline hydroxylamine solution R* to each tube. Allow the reaction to proceed for exactly 2 min and add 1.0 ml of *4 M hydrochloric acid* to each of the reaction tubes. Add 1.0 ml of a 100 g/l solution of *ferric chloride R* in *0.1 M hydrochloric acid* to each tube, stopper the tubes and shake vigorously to remove bubbles.

Measure the absorbance (*2.2.25*) of each solution at 540 nm using the blank as the compensation liquid. For each reaction solution, subtract the absorbance of the corresponding correction solution. Draw a calibration curve from the corrected absorbances for the 4 reference solutions and the corresponding content of acetylcholine chloride and read from the curve the content of acetylcholine chloride in the test solution for each volume tested. Calculate the mean of the 3 values.

1 mole of acetylcholine chloride (181.7 g) is equivalent to 1 mole of *O*-acetyl (43.05 g).

01/2008:20520

2.5.20. HEXOSAMINES IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 125 µg to 500 µg of glucosamine (hexosamine). Introduce 1.0 ml of the diluted solution into a graduated tube.

Reference solutions. Dissolve 60 mg of *glucosamine hydrochloride R* in 100 ml of *water R* (stock solution containing 0.500 g of glucosamine per litre). Introduce 0.25 ml, 0.50 ml, 0.75 ml, and 1.0 ml of the working dilution into 4 graduated tubes.

Prepare a blank using 1 ml of *water R*.

Make up the volume in each tube to 1 ml with *water R*. Add 1 ml of a solution of *hydrochloric acid R* (292 g/l) to each tube. Stopper the tubes and place in a water-bath for 1 h. Cool to room temperature. Add to each tube 0.05 ml of a 5 g/l solution of *thymolphthalein R* in *alcohol R*; add a solution of *sodium hydroxide R* (200 g/l) until a blue colour is obtained and then *1 M hydrochloric acid* until the solution is colourless. Dilute the volume in each tube to 10 ml with *water R* (neutralised hydrolysates).

In a second series of 10 ml graduated tubes, place 1 ml of each neutralised hydrolysate. Add 1 ml of acetylacetone reagent (a mixture, prepared immediately before use, of 1 volume of *acetylacetone R* and 50 volumes of a 53 g/l solution of *anhydrous sodium carbonate R*) to each tube. Stopper the tubes and place in a water-bath at 90 °C for 45 min. Cool to room temperature. Add to each tube 2.5 ml of *alcohol R* and 1.0 ml of dimethylaminobenzaldehyde solution (immediately before use dissolve 0.8 g of *dimethylaminobenzaldehyde R* in 15 ml of *alcohol R* and add 15 ml of *hydrochloric acid R*) and dilute the volume in each tube to 10 ml with *alcohol R*. Stopper the tubes, mix by inverting and allow to stand in the dark for 90 min. Measure the absorbance (*2.2.25*) of each solution at 530 nm using the blank as the compensation liquid.

Draw a calibration curve from the absorbances for the 4 reference solutions and the corresponding content of hexosamine and read from the curve the quantity of hexosamine in the test solution.

01/2008:20521

2.5.21. METHYLPENTOSES IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 2 µg to 20 µg of rhamnose (methylpentoses). Introduce 0.25 ml, 0.50 ml and 1.0 ml of the diluted solution into 3 tubes.

Reference solutions. Dissolve 0.100 g of *rhamnose R* in 100 ml of *water R* (stock solution containing 1 g of methylpentose per litre). Immediately before use, dilute 1 ml of the stock solution to 50 ml with *water R* (working dilution: 20 mg of methylpentose per litre). Introduce 0.10 ml, 0.25 ml, 0.50 ml, 0.75 ml and 1.0 ml of the working dilution into 5 tubes.

Prepare a blank using 1 ml of *water R*.

Make up the volume in each tube to 1 ml with *water R*. Place the tubes in iced water and add dropwise and with continuous stirring to each tube 4.5 ml of a cooled mixture of 1 volume of *water R* and 6 volumes of *sulphuric acid R*. Warm the tubes to room temperature and place in a water-bath for a few minutes. Cool to room temperature. Add to each tube 0.10 ml of a 30 g/l solution of *cysteine hydrochloride R*, prepared immediately before use. Shake and allow to stand for 2 h.

Measure the absorbance (*2.2.25*) of each solution at 396 nm and at 430 nm using the blank as compensation liquid. For each solution, calculate the difference between the absorbance measured at 396 nm and that measured at 430 nm. Draw a calibration curve from the absorbance differences for the 5 reference solutions and the corresponding content of methylpentose and read from the curve the quantity of methylpentose in the test solution for each volume tested. Calculate the mean of the 3 values.

01/2008:20522

2.5.22. URONIC ACIDS IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 4 µg to 40 µg of glucuronic acid (uronic acids). Introduce 0.25 ml, 0.50 ml and 1.0 ml of the diluted solution into 3 tubes.

Reference solutions. Dissolve 50 mg of *sodium glucuronate R* in 100 ml of *water R* (stock solution containing 0.4 g of glucuronic acid per litre). Immediately before use, dilute 5 ml of the stock solution to 50 ml with *water R* (working dilution: 40 mg of glucuronic acid per litre). Introduce 0.10 ml, 0.25 ml, 0.50 ml, 0.75 ml, and 1.0 ml of the working dilution into 5 tubes.

Prepare a blank using 1 ml of *water R*.

Make up the volume in each tube to 1 ml with *water R*. Place the tubes in iced water and add dropwise and with continuous stirring to each tube 5.0 ml of *borate solution R*. Stopper the tubes and place in a water-bath for 15 min. Cool to room temperature. Add 0.20 ml of a 1.25 g/l solution of *carbazole R* in *ethanol R* to each tube. Stopper the tubes and place in a water-bath for 15 min. Cool to room temperature. Measure the absorbance (*2.2.25*) of each solution at 530 nm using the blank as the compensation liquid.

Draw a calibration curve from the absorbances for the 5 reference solutions and the corresponding content of glucuronic acid and read from the curve the quantity of glucuronic acid in the test solution for each volume tested. Calculate the mean of the 3 values.

01/2008:20523

2.5.23. SIALIC ACID IN POLYSACCHARIDE VACCINES

Test solution. Transfer quantitatively the contents of one or several containers to a volumetric flask of a suitable volume that will give a solution with a known concentration of about 250 µg per millilitre of polysaccharide and dilute to volume with *water R*. Using a syringe, transfer 4.0 ml of this solution to a 10 ml ultrafiltration cell suitable for the passage of molecules of relative molecular mass less than 50 000. Rinse the syringe twice with *water R* and transfer the rinsings to the ultrafiltration cell. Carry out the ultrafiltration, with constant stirring, under *nitrogen R* at a pressure of about 150 kPa. Refill the cell with *water R* each time the volume of liquid in it has decreased to 1 ml and continue until 200 ml has been filtered and the remaining volume in the cell is about 2 ml. Using a syringe, transfer this residual liquid to a 10 ml volumetric flask. Wash the cell with 3 quantities, each of 2 ml, of *water R*, transfer the washings to the flask and dilute to 10.0 ml with *water R* (test solution). In each of 2 test-tubes place 2.0 ml of the test solution.

Reference solutions. Use the reference solutions prescribed in the monograph.

Prepare 2 series of 3 test-tubes, place in the tubes of each series 0.5 ml, 1.0 ml and 1.5 ml respectively, of the reference solution corresponding to the type of vaccine to be examined and adjust the volume in each tube to 2.0 ml with *water R*.

Prepare blank solutions using 2.0 ml of *water R* in each of 2 test-tubes.

To all the tubes add 5.0 ml of *resorcinol reagent R*. Heat at 105 °C for 15 min, cool in cold water and transfer the tubes to a bath of iced water. To each tube add 5 ml of *isoamyl alcohol R* and mix thoroughly. Place in the bath of iced water for 15 min. Centrifuge the tubes and keep them in the bath of iced water until the examination by absorption spectrophotometry. Measure the absorbance (*2.2.25*) of each supernatant solution at 580 nm and 450 nm using *isoamyl alcohol R* as the compensation liquid. For each wavelength, calculate the absorbance as the mean of the values obtained with 2 identical solutions. Subtract the mean value for the blank solution from the mean values obtained for the other solutions.

Draw a graph showing the difference between the absorbances at 580 nm and 450 nm of the reference solutions as a function of the content of *N*-acetylneuraminic acid and read from the graph the quantity of *N*-acetylneuraminic acid (sialic acid) in the test solution.

2.5.24. CARBON DIOXIDE IN GASES

Carbon dioxide in gases is determined using an infrared analyser (see Figure 2.5.24.-1).

The infrared analyser comprises 2 generators of identical infrared beams. The generators are equipped with reflectors and coils electrically heated to low red heat. One beam crosses a sample cell and the other beam crosses a reference cell. The sample cell receives a stream of the gas to be analysed and the reference cell contains *nitrogen R1*. The 2 chambers of the detector are filled with *carbon dioxide R1* and the radiation is automatically received selectively. The absorption of this radiation produces heat and differential expansion of the gas in the 2 chambers, owing to absorption of some of the emitted radiation by the carbon dioxide in the gas to be examined. The pressure difference between the 2 chambers of the detector causes distension of the metal diaphragm that separates them. This diaphragm is part of a capacitor, whose capacitance varies with the pressure difference, which itself depends on the carbon dioxide content in the gas to be examined. Since the infrared beams are periodically blocked by a rotating chopper, the electric signal is frequency modulated.

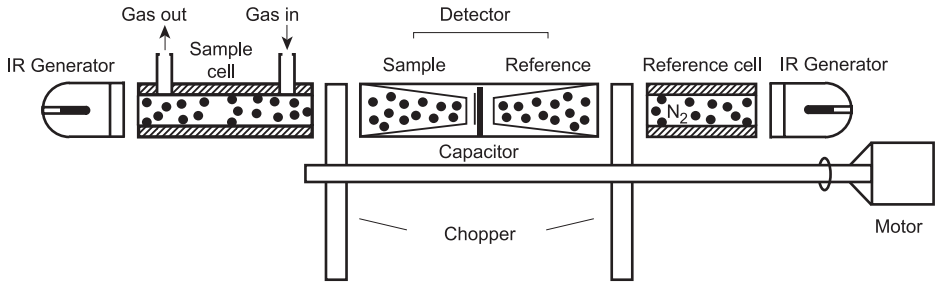

Figure 2.5.24.-1. – *Infrared analyser*

01/2008:20525

2.5.25. CARBON MONOXIDE IN GASES

METHOD I

Apparatus. The apparatus (see Figure 2.5.25.-1) consists of the following parts connected in series:

- a U-tube (U_1) containing *anhydrous silica gel R* impregnated with *chromium trioxide R*,
- a wash bottle (F_1) containing 100 ml of a 400 g/l solution of *potassium hydroxide R*,
- a U-tube (U_2) containing pellets of *potassium hydroxide R*,
- a U-tube (U_3) containing *diphosphorus pentoxide R* dispersed on previously granulated, fused pumice,
- a U-tube (U_4) containing 30 g of *recrystallised iodine pentoxide R* in granules, previously dried at 200 °C and kept at a temperature of 120 °C (*T*) during the test. The iodine pentoxide is packed in the tube in 1 cm columns separated by 1 cm columns of glass wool to give an effective length of 5 cm,
- a reaction tube (F_2) containing 2.0 ml of *potassium iodide solution R* and 0.15 ml of *starch solution R*.

Method. Flush the apparatus with 5.0 litres of *argon R* and, if necessary, discharge the blue colour in the iodide solution by adding the smallest necessary quantity of freshly prepared *0.002 M sodium thiosulphate*. Continue flushing until not more than 0.045 ml of *0.002 M sodium thiosulphate* is required after passage of 5.0 litres of *argon R*. Pass the gas to be examined from the cylinder through the apparatus, using the prescribed volume and the flow rate. Flush the last traces of liberated iodine into the reaction tube by passing through the apparatus 1.0 litre of *argon R*. Titrate the liberated iodine with *0.002 M sodium thiosulphate*. Carry out a blank test, using the prescribed volume of *argon R*. The difference between the volumes of *0.002 M sodium thiosulphate* used in the titrations is not greater than the prescribed limit.

METHOD II

Carbon monoxide in gases may also be determined using an infrared analyser (see Figure 2.5.25.-2).

The infrared analyser comprises 2 generators of identical infrared beams. The generators are equipped with reflectors and coils electrically heated to low red heat. One beam crosses a sample cell and the other beam crosses a reference cell. The sample cell receives a current of the gas to be analysed and the reference cell contains *nitrogen R1*. The 2 chambers of the detector are filled with *carbon monoxide R* and the radiation is automatically received selectively. The absorption of this radiation produces heat and differential expansion of the gas in the two chambers, owing to absorption of some of the emitted radiation by the carbon monoxide in the gas to be examined. The pressure difference between the two chambers of the detector causes distension of the metal diaphragm that separates them. This diaphragm is part of a capacitor, whose capacitance varies with the pressure difference, which itself depends on the carbon monoxide content in the gas to be examined. Since the infrared beams are periodically blocked by a rotating chopper, the electric signal is frequency modulated.

2.5.26. NITROGEN MONOXIDE AND NITROGEN DIOXIDE IN GASES

Nitrogen monoxide and nitrogen dioxide in gases are determined using a chemiluminescence analyser (Figure 2.5.26.-1).

The apparatus consists of the following:

- a device for filtering, checking and controlling the flow of the gas to be examined,
- a converter that reduces nitrogen dioxide to nitrogen monoxide, to determine the combined content of nitrogen monoxide and nitrogen dioxide. The efficiency of the converter has to be verified prior to use,
- a controlled-flow-rate ozone generator; the ozone is produced by high-voltage electric discharges across two electrodes; the ozone generator is supplied with pure oxygen or with dehydrated ambient air and the concentration of ozone obtained must greatly exceed the maximum content of any detectable nitrogen oxides,
- a chamber in which nitrogen monoxide and ozone can react,
- a system for detecting light radiation emitted at a wavelength of 1.2 µm, consisting of a selective optical filter and a photomultiplier tube.

01/2008:20527

2.5.27. OXYGEN IN GASES

Oxygen in gases is determined using a paramagnetic analyser.

The principle of the method is based on the high paramagnetic sensitivity of the oxygen molecule. Oxygen exerts a strong interaction on magnetic fields, which is measured electronically, amplified and converted to a reading of oxygen concentration. The measurement of oxygen concentration is dependent upon the pressure and temperature and, if the analyser is not automatically compensated for variations in temperature and pressure, it must be calibrated immediately prior to use. As the paramagnetic effect of oxygen is linear the instrument must have a suitable range with a readability of 0.1 per cent or better.

Calibration of the instrument. Make the setting in the following manner:

- set the zero by passing *nitrogen R1* through the instrument at a suitable flow rate until a constant reading is obtained. It should be set to zero according to the manufacturer's instructions;
- set the appropriate limit by passing air (20.9 per cent *V/V* O_2) through the instrument at a suitable flow rate until a constant reading is obtained. The limit should be set to 20.9 per cent *V/V* in accordance with the manufacturer's instructions.

Assay. Pass the gas to be examined through the instrument at a constant flow rate until a suitable reading is obtained.

01/2008:20528

2.5.28. WATER IN GASES

Water in gases is determined using an electrolytic hygrometer, described below.

The measuring cell consists of a thin film of diphosphorus pentoxide, between 2 coiled platinum wires which act as electrodes. The water vapour in the gas to be examined is absorbed by the diphosphorus pentoxide, which is transformed to phosphoric acid, an electrical conductor. A continuous voltage applied across the electrodes produces electrolysis of the water and the regeneration of the diphosphorus pentoxide. The resulting electric current, which is proportional to the water content in the gas to be examined, is measured. This system is self-calibrating since it obeys Faraday's law.

Take a sample of the gas to be examined. Allow the gas to stabilise at room temperature. Purge the cell continuously until a stable reading is obtained. Measure the water content in the gas to be examined, making sure that the temperature is constant throughout the device used to introduce the gas into the apparatus.

01/2008:20529

2.5.29. SULPHUR DIOXIDE

Introduce 150 ml of *water R* into the flask (*A*) (see Figure 2.5.29.-1) and pass *carbon dioxide R* through the whole system for 15 min at a rate of 100 ml/min. To 10 ml of *dilute hydrogen peroxide solution R* add 0.15 ml of a 1 g/l solution of *bromophenol blue R* in *alcohol (20 per*

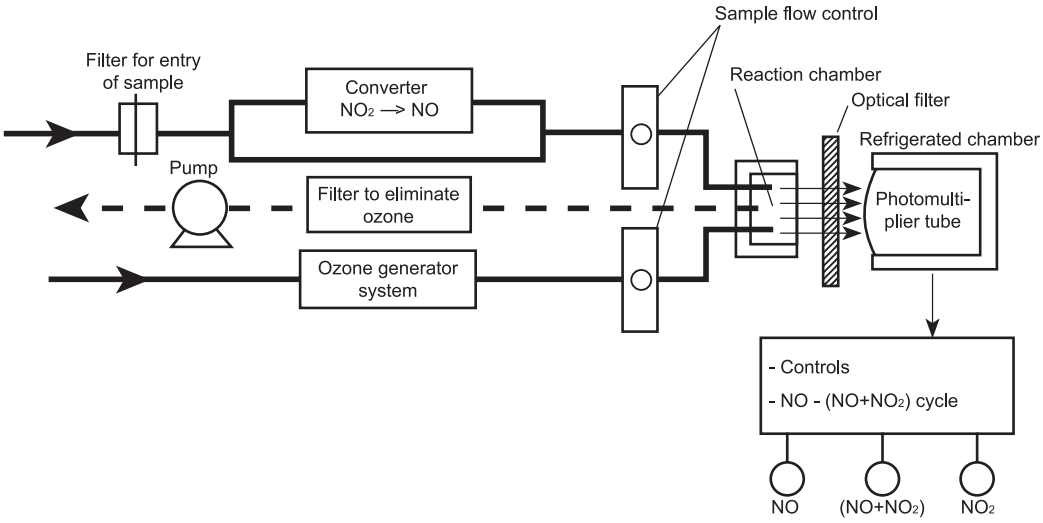

Figure 2.5.26.-1. – *Chemiluminescence analyser*

cent V/V) R. Add *0.1 M sodium hydroxide* until a violet-blue colour is obtained, without exceeding the end-point. Place the solution in the test-tube (*D*). Without interrupting the stream of carbon dioxide, remove the funnel (*B*) and introduce through the opening into the flask (*A*) 25.0 g of the substance to be examined (*m* g) with the aid of 100 ml of *water R*. Add through the funnel 80 ml of *dilute hydrochloric acid R* and boil for 1 h. Open the tap of the funnel and stop the flow of carbon dioxide and also the heating and the cooling water. Transfer the contents of the test-tube with the aid of a little *water R* to a 200 ml wide-necked, conical flask. Heat on a water-bath for 15 min and allow to cool. Add 0.1 ml of a 1 g/l solution of *bromophenol blue R* in *alcohol (20 per cent V/V) R* and titrate with *0.1 M sodium hydroxide* until the colour changes from yellow to violet-blue (V_1 ml). Carry out a blank titration (V_2 ml).

Calculate the content of sulphur dioxide in parts per million from the expression:

$$32\,030 \times (V_1 - V_2) \times \frac{n}{m}$$

n = molarity of the sodium hydroxide solution used as titrant.

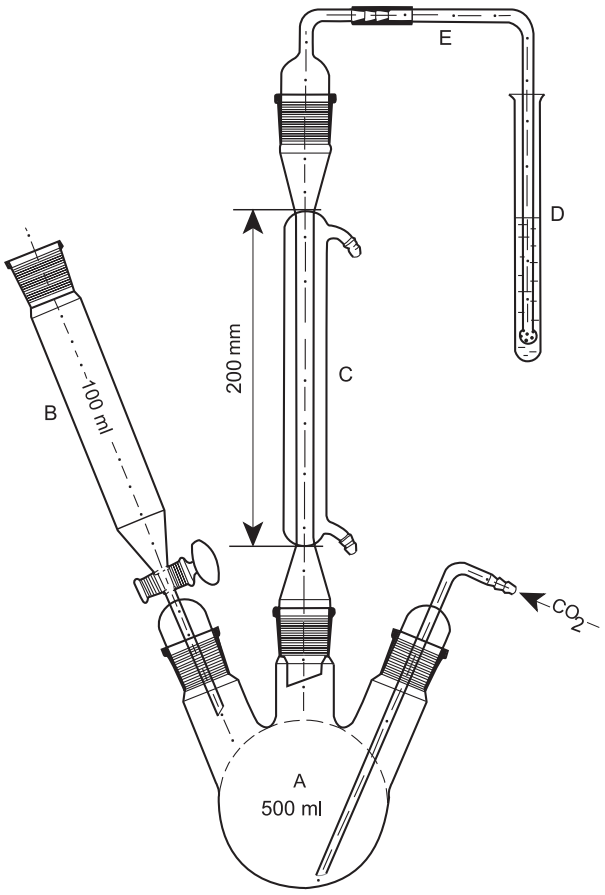

Figure 2.5.29.-1.– *Apparatus for the determination of sulphur dioxide*

01/2008:20530

2.5.30. OXIDISING SUBSTANCES

Transfer 4.0 g to a glass-stoppered, 125 ml conical flask and add 50.0 ml of *water R*. Insert the stopper and swirl for 5 min. Transfer to a glass-stoppered 50 ml centrifuge tube and centrifuge. Transfer 30.0 ml of the clear supernatant liquid to a glass-stoppered 125 ml conical flask. Add 1 ml of *glacial acetic acid R* and 0.5 g to 1.0 g of *potassium iodide R*. Insert the stopper, swirl, and allow to stand for 25 min to 30 min in the dark. Add 1 ml of *starch solution R* and titrate with *0.002 M sodium thiosulphate* until the starch-iodine colour disappears. Carry out a blank determination. Not more than 1.4 ml of *0.002 M sodium thiosulphate* is required (0.002 per cent, calculated as H_2O_2).

1 ml of *0.002 M sodium thiosulphate* is equivalent to 34 µg of oxidising substances, calculated as hydrogen peroxide.

01/2008:20531

2.5.31. RIBOSE IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 2.5 µg to 25 µg of ribose. Introduce 0.20 ml and 0.40 ml of the diluted solution into tubes in triplicate.

Reference solutions. Dissolve 25 mg of *ribose R* in *water R* and dilute to 100.0 ml with the same solvent (stock solution containing 0.25 g/l of ribose). Immediately before use, dilute 1 ml of the stock solution to 10.0 ml with *water R* (working dilution: 25 mg/l of ribose). Introduce 0.10 ml, 0.20 ml, 0.40 ml, 0.60 ml, 0.80 ml and 1.0 ml of the working dilution into 6 tubes.

Prepare a blank using 2 ml of *water R*.

Make up the volume in each tube to 2 ml with *water R*. Shake. Add 2 ml of a 0.5 g/l solution of *ferric chloride R* in *hydrochloric acid R* to each tube. Shake. Add 0.2 ml of a 100 g/l solution of *orcinol R* in *ethanol R*. Place the tubes in a water-bath for 20 min. Cool in iced water. Measure the absorbance (*2.2.25*) of each solution at 670 nm using the blank as the compensation liquid. Draw a calibration curve from the absorbance readings for the 6 reference solutions and the corresponding content of ribose and read from the curve the quantity of ribose in the test solution for each volume tested. Calculate the mean of the 3 values.

01/2008:20532

2.5.32. WATER: MICRO DETERMINATION

PRINCIPLE

The coulometric titration of water is based upon the quantitative reaction of water with sulphur dioxide and iodine in an anhydrous medium in the presence of a base with sufficient buffering capacity. In contrast to the volumetric method described under (*2.5.12*), iodine is produced electrochemically in the reaction cell by oxidation of iodide. The iodine produced at the anode reacts immediately with the water and the sulphur dioxide contained in the reaction cell. The amount of water in the substance is directly proportional to the quantity of electricity up until the titration end-point. When all of the water in the cell has been consumed, the end-point is reached and thus an excess of iodine appears. 1 mole of iodine corresponds to 1 mole of water, a quantity of electricity of 10.71 C corresponds to 1 mg of water.

Moisture is eliminated from the system by pre-electrolysis. Individual determinations can be carried out successively in the same reagent solution, under the following conditions:

– each component of the test mixture is compatible with the other components,
– no other reactions take place,
– the volume and the water capacity of the electrolyte reagent are sufficient.

Coulometric titration is restricted to the quantitative determination of small amounts of water, a range of 10 µg up to 10 mg of water is recommended.

Accuracy and precision of the method are predominantly governed by the extent to which atmospheric moisture is excluded from the system. Control of the system must be monitored by measuring the amount of baseline drift.

APPARATUS

The apparatus consists of a reaction cell, electrodes and magnetic stirrer. The reaction cell consists of a large anode compartment and a smaller cathode compartment. Depending on the design of the electrode, both compartments can be separated by a diaphragm. Each compartment contains a platinum electrode. Liquid or solubilised samples are introduced through a septum, using a syringe. Alternatively, an evaporation technique may be used in which the sample is heated in a tube (oven) and the water is evaporated and carried into the cell by means of a stream of dry inert gas. The introduction of solid samples into the cell should in general be avoided. However, if it has to be done it is effected through a sealable port; appropriate precautions must be taken to avoid the introduction of moisture from air, such as working in a glove box in an atmosphere of dry inert gas. The analytical procedure is controlled by a suitable electronic device, which also displays the results.

METHOD

Fill the compartments of the reaction cell with *electrolyte reagent for the micro determination of water R* according to the manufacturer's instructions and perform the coulometric titration to a stable end-point. Introduce the prescribed amount of the substance to be examined into the reaction cell, stir for 30 s, if not otherwise indicated in the monograph, and titrate again to a stable end-point. In case an oven is used, the prescribed sample amount is introduced into the tube and heated. After evaporation of the water from the sample into the titration cell, the titration is started. Read the value from the instrument's output and calculate if necessary the percentage or amount of water that is present in the substance. When appropriate to the type of sample and the sample preparation, perform a blank titration.

VERIFICATION OF THE ACCURACY

Between two successive sample titrations, introduce an accurately weighed amount of water in the same order of magnitude as the amount of water in the sample, either as *water R* or in the form of *standard solution for the micro determination of water R*, and perform the coulometric titration. The recovery rate is within the range from 97.5 per cent to 102.5 per cent for an addition of 1000 µg of H_2O and in the range from 90.0 per cent to 110.0 per cent for the addition of 100 µg of H_2O.

corrected 6.0

2.5.33. TOTAL PROTEIN

Many of the assay methods described in this chapter can be performed using kits from commercial sources.

METHOD 1

Protein in solution absorbs ultraviolet light at a wavelength of 280 nm, due to the presence of aromatic amino acids, mainly tyrosine and tryptophan, in the protein structure. This property can be used for assay purposes. If the buffer used to dissolve the protein has a high absorbance relative to that of water, an interfering substance is present. This interference may be obviated by using the buffer as compensation liquid but if the interfering substance produces a high absorbance, the results may nevertheless be compromised. At low concentrations, protein adsorbed onto the cell may significantly reduce the content in solution. This can be prevented by preparing samples at higher concentration or by using a non-ionic detergent in the preparation.

Test solution. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a protein concentration between 0.2 mg/ml and 2 mg/ml.

Reference solution. Prepare a solution of a suitable reference substance for the protein to be determined, in the same buffer and at the same protein concentration as the test solution.

Procedure. Keep the test solution, the reference solution and the compensation liquid at the same temperature during the performance of this test. Determine the absorbances (*2.2.25*) of the test solution and the reference solution in quartz cells at 280 nm, using the prescribed buffer as the compensation liquid. The response must be linear in the range of protein concentrations to be assayed to obtain accurate results.

Light scattering. The accuracy of the determination of protein can be diminished by the scattering of light by the test sample. If the proteins in solution exist as particles comparable in size to the wavelength of the measuring light (250 nm to 300 nm), scattering of the light beam results in an apparent increase in absorbance of the test sample. To calculate the absorbance at 280 nm due to light scattering, determine the absorbances of the test solution at wavelengths of 320 nm, 325 nm, 330 nm, 335 nm, 340 nm, 345 nm and 350 nm. Plot the logarithm of the observed absorbance against the logarithm of the wavelength and determine the standard curve best fitting the plotted points by linear regression. Extrapolate the curve to determine the logarithm of the absorbance at 280 nm. The antilogarithm of this value is the absorbance attributed to light scattering. Correct the observed values by subtracting the absorbance attributed to light scattering from the total absorbance at 280 nm to obtain the absorbance value of the protein in solution. Filtration with a 0.2 µm filter that does not adsorb protein or clarification by centrifugation may be performed to reduce the effect of light scattering, especially if the solution is noticeably turbid.

Calculations. Use corrected values for the calculations. Calculate the concentration of protein in the test solution (C_U) from the following equation:

$$C_U = C_S \, (A_U / A_S)$$

where C_S is the concentration of protein in the reference solution and A_U and A_S are the corrected absorbances of the test solution and the reference solution, respectively.

METHOD 2

This method (commonly referred to as the Lowry assay) is based on the reduction by protein of the phosphomolybdotungstic mixed acid chromogen in the phosphomolybdotungstic reagent, which results in an absorbance maximum at 750 nm. The phosphomolybdotungstic reagent reacts primarily with

tyrosine residues in the protein. Colour development reaches a maximum in 20 min to 30 min at room temperature, after which there is a gradual loss of colour. Because the method is sensitive to interfering substances, a procedure for precipitation of the protein from the test sample may be used. Most interfering substances cause a lower colour yield; however, some detergents cause a slight increase in colour. A high salt concentration may cause a precipitate to form. Because different protein species may give different colour response intensities, the reference substance and test protein must be the same. Where separation of interfering substances from the protein in the test sample is necessary, proceed as directed below for interfering substances prior to preparation of the test solution. The effect of interfering substances may be minimised by dilution, provided the concentration of the test protein remains sufficient for accurate measurement.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the standard curve. A suitable buffer will produce a solution of pH 10.0 to 10.5.

Reference solutions. Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 5 µg/ml and 100 µg/ml.

Blank. Use the buffer used to prepare the test solution and the reference solutions.

Copper sulphate reagent. Dissolve 100 mg of *copper sulphate R* and 0.2 g of *sodium tartrate R* in *distilled water R* and dilute to 50 ml with the same solvent. Dissolve 10 g of *anhydrous sodium carbonate R* in *distilled water R* and dilute to 50 ml with the same solvent. Slowly pour the sodium carbonate solution into the copper sulphate solution with mixing. Use within 24 h.

Alkaline copper reagent. Mix 1 volume of copper sulphate reagent, 2 volumes of a 50 g/l solution of *sodium dodecyl sulphate R* and 1 volume of a 32 g/l solution of *sodium hydroxide R*. Store at room temperature and use within 2 weeks.

Diluted phosphomolybdotungstic reagent. Mix 5 ml of *phosphomolybdotungstic reagent R* with 55 ml of *distilled water R*. Store in an amber bottle, at room temperature.

Procedure. To 1.0 ml of each reference solution, of the test solution and of the blank, add 1.0 ml of alkaline copper reagent and mix. Allow to stand for 10 min. Add 0.5 ml of the diluted phosphomolybdotungstic reagent, mix and allow to stand at room temperature for 30 min. Determine the absorbances (*2.2.25*) of the solutions at 750 nm, using the solution from the blank as compensation liquid.

Calculations. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against the protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

Interfering substances. In the following procedure, deoxycholate-trichloroacetic acid is added to a test sample to remove interfering substances by precipitation of proteins before determination; this technique can also be used to concentrate proteins from a dilute solution.

Add 0.1 ml of a 1.5 g/l solution of *sodium deoxycholate R* to 1 ml of a solution of the substance to be examined. Mix using a vortex mixer and allow to stand at room temperature for 10 min. Add 0.1 ml of a 720 g/l solution of *trichloroacetic acid R* and mix using a vortex mixer. Centrifuge at 3000 *g* for 30 min, decant the liquid and remove any residual liquid with a pipette. Redissolve the protein pellet in 1 ml of alkaline copper reagent.

METHOD 3

This method (commonly referred to as the Bradford assay) is based on the absorption shift from 470 nm to 595 nm observed when the acid blue 90 dye binds to protein. The acid blue 90 dye binds most readily to arginine and lysine residues in the protein which can lead to variation in the response of the assay to different proteins. The protein used as reference substance must therefore be the same as the protein to be determined. There are relatively few interfering substances, but it is preferable to avoid detergents and ampholytes in the test sample. Highly alkaline samples may interfere with the acidic reagent.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the standard curve.

Reference solutions. Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 0.1 mg/ml and 1 mg/ml.

Blank. Use the buffer used to prepare the test solution and the reference solutions.

Acid blue 90 reagent. Dissolve 0.10 g of *acid blue 90 R* in 50 ml of *alcohol R*. Add 100 ml of *phosphoric acid R*, dilute to 1000 ml with *distilled water R* and mix. Filter the solution and store in an amber bottle at room temperature. Slow precipitation of the dye occurs during storage. Filter the reagent before using.

Procedure. Add 5 ml of acid blue 90 reagent to 0.100 ml of each reference solution, of the test solution and of the blank. Mix by inversion. Avoid foaming, which will lead to poor reproducibility. Determine the absorbances (*2.2.25*) of the standard solutions and of the test solution at 595 nm, using the blank as compensation liquid. Do not use quartz (silica) spectrophotometer cells because the dye binds to this material.

Calculations. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

METHOD 4

This method (commonly referred to as the bicinchoninic acid or BCA assay) is based on reduction of the cupric (Cu^{2+}) ion to cuprous (Cu^{1+}) ion by protein. The bicinchoninic acid reagent is used to detect the cuprous ion. Few substances interfere with the reaction. When interfering substances are present their effect may be minimised by dilution, provided that the concentration of the protein to be determined remains sufficient for accurate measurement. Alternatively, the protein precipitation procedure given in Method 2 may be used to remove interfering substances. Because different protein species may give different colour response intensities, the reference protein and protein to be determined must be the same.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the concentrations of the reference solutions.

Reference solutions. Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 10 µg/ml and 1200 µg/ml.

Blank. Use the buffer used to prepare the test solution and the reference solutions.

BCA reagent. Dissolve 10 g of *disodium bicinchoninate R*, 20 g of *sodium carbonate monohydrate R*, 1.6 g of *sodium tartrate R*, 4 g of *sodium hydroxide R*, and 9.5 g of *sodium hydrogen carbonate R* in *distilled water R*. Adjust, if necessary, to pH 11.25 with a solution of *sodium hydroxide R* or a solution of *sodium hydrogen carbonate R*. Dilute to 1000 ml with *distilled water R* and mix.

Copper-BCA reagent. Mix 1 ml of a 40 g/l solution of *copper sulphate R* and 50 ml of BCA reagent.

Procedure. Mix 0.1 ml of each reference solution, of the test solution and of the blank with 2 ml of the copper-BCA reagent. Incubate the solutions at 37 °C for 30 min, note the time and allow the mixtures to cool to room temperature. Within 60 min of the end of incubation, determine the absorbances (*2.2.25*) of the reference solutions and of the test solution in quartz cells at 562 nm, using the blank as compensation liquid. After the solutions have cooled to room temperature, the colour intensity continues to increase gradually.

Calculations. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

METHOD 5

This method (commonly referred to as the biuret assay) is based on the interaction of cupric (Cu^{2+}) ion with protein in alkaline solution and resultant development of absorbance at 545 nm. This test shows minimal difference between equivalent IgG and albumin samples. Addition of the sodium hydroxide and the biuret reagent as a combined reagent, insufficient mixing after the addition of the sodium hydroxide, or an extended time between the addition of the sodium hydroxide solution and the addition of the biuret reagent will give IgG samples a higher response than albumin samples. The trichloroacetic acid method used to minimise the effects of interfering substances also can be used to determine the protein content in test samples at concentrations below 500 µg/ml.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in a 9 g/l solution of *sodium chloride R* to obtain a solution having a concentration within the range of the concentrations of the reference solutions.

Reference solutions. Dissolve the reference substance for the protein to be determined in a 9 g/l solution of *sodium chloride R*. Dilute portions of this solution with a 9 g/l solution of *sodium chloride R* to obtain not fewer than three reference solutions having protein concentrations evenly spaced over a suitable range situated between 0.5 mg/ml and 10 mg/ml.

Blank. Use a 9 g/l solution of *sodium chloride R*.

Biuret reagent. Dissolve 3.46 g of *copper sulphate R* in 10 ml of hot *distilled water R*, and allow to cool (Solution A). Dissolve 34.6 g of *sodium citrate R* and 20.0 g of *anhydrous sodium carbonate R* in 80 ml of hot *distilled water R*, and allow to cool (Solution B). Mix solutions A and B and dilute to 200 ml with *distilled water R*. Use within 6 months. Do not use the reagent if it develops turbidity or contains any precipitate.

Procedure. To one volume of the test solution add an equal volume of a 60 g/l solution of *sodium hydroxide R* and mix. Immediately add biuret reagent equivalent to 0.4 volumes of the test solution and mix rapidly. Allow to stand at a temperature between 15 °C and 25 °C for not less than 15 min. Within 90 min of addition of the biuret reagent, determine the absorbances (*2.2.25*) of the reference solutions and of the test solution at the maximum at 545 nm, using the blank as compensation liquid. Any solution that develops turbidity or a precipitate is not acceptable for calculation of protein concentration.

Calculations. The relationship of absorbance to protein concentration is approximately linear within the indicated range of protein concentrations for the reference solutions. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. Calculate the correlation coefficient for the standard curve. A suitable system is one that yields a line having a correlation coefficient not less than 0.99. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

Interfering substances. To minimise the effect of interfering substances, the protein can be precipitated from the test sample as follows: add 0.1 volumes of a 500 g/l solution of *trichloroacetic acid R* to 1 volume of a solution of the test sample, withdraw the supernatant layer and dissolve the precipitate in a small volume of *0.5 M sodium hydroxide*. Use the solution obtained to prepare the test solution.

METHOD 6

This fluorimetric method is based on the derivatisation of the protein with *o*-phthalaldehyde, which reacts with the primary amines of the protein (*N*-terminal amino acid and the ϵ-amino group of lysine residues). The sensitivity of the assay can be increased by hydrolysing the protein before adding *o*-phthalaldehyde. Hydrolysis makes the α-amino group of the constituent amino acids available for reaction with the phthalaldehyde reagent. The method requires very small quantities of the protein. Primary amines, such as tris(hydroxymethyl)aminomethane and amino acid

buffers, react with phthalaldehyde and must be avoided or removed. Ammonia at high concentrations reacts with phthalaldehyde. The fluorescence obtained when amine reacts with phthalaldehyde can be unstable. The use of automated procedures to standardise this procedure may improve the accuracy and precision of the test.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in a 9 g/l solution of *sodium chloride R* to obtain a solution having a concentration within the range of the concentrations of the reference solutions. Adjust the solution to pH 8 to 10.5 before addition of the phthalaldehyde reagent.

Reference solutions. Dissolve the reference substance for the protein to be determined in a 9 g/l solution of *sodium chloride R*. Dilute portions of this solution with a 9 g/l solution of *sodium chloride R* to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 10 µg/ml and 200 µg/ml. Adjust the solutions to pH 8 to 10.5 before addition of the phthalaldehyde reagent.

Blank solution. Use a 9 g/l solution of *sodium chloride R*.

Borate buffer solution. Dissolve 61.83 g of *boric acid R* in *distilled water R* and adjust to pH 10.4 with a solution of *potassium hydroxide R*. Dilute to 1000 ml with *distilled water R* and mix.

Phthalaldehyde stock solution. Dissolve 1.20 g of *phthalaldehyde R* in 1.5 ml of *methanol R*, add 100 ml of borate buffer solution and mix. Add 0.6 ml of a 300 g/l solution of *macrogol 23 lauryl ether R* and mix. Store at room temperature and use within 3 weeks.

Phthalaldehyde reagent. To 5 ml of phthalaldehyde stock solution add 15 µl of *2-mercaptoethanol R*. Prepare at least 30 min before use. Use within 24 h.

Procedure. Mix 10 µl of the test solution and of each of the reference solutions with 0.1 ml of phthalaldehyde reagent and allow to stand at room temperature for 15 min. Add 3 ml of *0.5 M sodium hydroxide* and mix. Determine the fluorescent intensities (*2.2.21*) of solutions from the reference solutions and from the test solution at an excitation wavelength of 340 nm and an emission wavelength between 440 and 455 nm. Measure the fluorescent intensity of a given sample only once, since irradiation decreases the fluorescence intensity.

Calculations. The relationship of fluorescence to protein concentration is linear. Plot the fluorescent intensities of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the fluorescent intensity of the test solution, determine the concentration of protein in the test solution.

METHOD 7

This method is based on nitrogen analysis as a means of protein determination. Interference caused by the presence of other nitrogen-containing substances in the test sample can affect the determination of protein by this method. Nitrogen analysis techniques destroy the test sample during the analysis but are not limited to protein presentation in an aqueous environment.

Procedure A. Proceed as prescribed for the determination of nitrogen by sulphuric acid digestion (*2.5.9*) or use commercial instrumentation for Kjeldahl nitrogen assay.

Procedure B. Commercial instrumentation is available for nitrogen analysis. Most nitrogen analysis instruments use pyrolysis (i.e. combustion of the sample in oxygen at temperatures approaching 1000 °C), which produces nitric oxide (NO) and other oxides of nitrogen (NO_x) from the nitrogen present in the substance to be examined. Some instruments convert the nitric oxides to nitrogen gas, which is quantified using a thermal-conductivity detector. Other instruments mix nitric oxide (NO) with ozone (O_3) to produce excited nitrogen dioxide (NO_2^*), which emits light when it decays and can be quantified with a chemiluminescence detector. A protein reference material that is relatively pure and is similar in composition to the test proteins is used to optimise the injection and pyrolysis parameters and to evaluate consistency in the analysis.

Calculations. The protein concentration is calculated by dividing the nitrogen content of the sample by the known nitrogen content of the protein. The known nitrogen content of the protein can be determined from the chemical composition of the protein or by comparison with a suitable reference substance.

01/2008:20534

2.5.34. ACETIC ACID IN SYNTHETIC PEPTIDES

Examine by liquid chromatography (*2.2.29*).

Test solution. Prepare as described in the monograph. The concentration of peptide in the solution may be adapted, depending on the expected amount of acetic acid in the sample.

Reference solution. Prepare a 0.10 g/l solution of *glacial acetic acid R* in a mixture of 5 volumes of mobile phase B and 95 volumes of mobile phase A.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),

– as mobile phase at a flow rate of 1.2 ml/min:

Mobile phase A. Dilute 0.7 ml of *phosphoric acid R* to 1000 ml with *water R*; adjust the pH to 3.0 with *strong sodium hydroxide solution R*,

Mobile phase B. *Methanol R2*,

Time (min)	Mobile phase A (per cent *V/V*)	Mobile phase B (per cent *V/V*)
0 - 5	95	5
5 - 10	95 → 50	5 → 50
10 - 20	50	50
20 - 22	50 → 95	50 → 5
22 - 30	95	5

– as detector a spectrophotometer set at 210 nm.

Inject 10 µl of the reference solution and 10 µl of the test solution. In the chromatograms obtained, the peak corresponding to acetic acid has a retention time of 3-4 min. The baseline presents a steep rise after the start of the linear gradient, which corresponds to the elution of the peptide from the column. Determine the content of acetic acid in the peptide.

2.5.35. NITROUS OXIDE IN GASES

Nitrous oxide in gases is determined using an infrared analyser (see Figure 2.5.35.-1).

The infrared analyser comprises 2 generators of identical infrared beams. The generators are equipped with reflectors and coils electrically heated to low red heat. One beam crosses a sample cell and the other beam crosses a reference cell. The sample cell receives a stream of the gas to be examined and the reference cell contains *nitrogen R1*. The 2 chambers of the detector are filled with *nitrous oxide R* and the radiation is automatically received selectively. The absorption of this radiation produces heat and differential expansion of the gas in the 2 chambers, owing to absorption of some of the emitted radiation by the nitrous oxide in the gas to be examined. The pressure difference between the 2 chambers of the detector causes distension of the metal diaphragm that separates them. This diaphragm is part of a capacitor, whose capacitance varies with the pressure difference, which itself depends on the nitrous oxide content in the gas to be examined. Since the infrared beams are periodically blocked by a rotating chopper, the electric signal is frequency modulated.

01/2008:20536

2.5.36. ANISIDINE VALUE

The anisidine value is defined as 100 times the optical density measured in a 1 cm cell of a solution containing 1 g of the substance to be examined in 100 ml of a mixture of solvents and reagents according to the following method.

Carry out the operations as rapidly as possible, avoiding exposure to actinic light.

Test solution (a). Dissolve 0.500 g of the substance to be examined in *trimethylpentane R* and dilute to 25.0 ml with the same solvent.

Test solution (b). To 5.0 ml of test solution (a) add 1.0 ml of a 2.5 g/l solution of *p-anisidine R* in *glacial acetic acid R*, shake and store protected from light.

Reference solution. To 5.0 ml of *trimethylpentane R* add 1.0 ml of a 2.5 g/l solution of *p-anisidine R* in *glacial acetic acid R*, shake and store protected from light.

Measure the absorbance (*2.2.25*) of test solution (a) at the maximum at 350 nm using *trimethylpentane R* as the compensation liquid. Measure the absorbance of test solution (b) at 350 nm exactly 10 min after its preparation, using the reference solution as the compensation liquid.

Calculate the anisidine value from the expression:

$$\frac{25 \times (1.2A_1 - A_2)}{m}$$

A_1 = absorbance of test solution (b) at 350 nm,

A_2 = absorbance of test solution (a) at 350 nm,

m = mass of the substance to be examined in test solution (a), in grams.

2.6. BIOLOGICAL TESTS

01/2008:20601

2.6.1. STERILITY

The test is applied to substances, preparations or articles which, according to the Pharmacopoeia, are required to be sterile. However, a satisfactory result only indicates that no contaminating micro-organism has been found in the sample examined in the conditions of the test. Guidance for using the test for sterility is given at the end of this text.

PRECAUTIONS AGAINST MICROBIAL CONTAMINATION

The test for sterility is carried out under aseptic conditions. In order to achieve such conditions, the test environment has to be adapted to the way in which the sterility test is performed. The precautions taken to avoid contamination are such that they do not affect any micro-organisms which are to be revealed in the test. The working conditions in which the tests are performed are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls (such as those indicated in the appropriate European Community Directives and associated guidance documents on GMP).

CULTURE MEDIA AND INCUBATION TEMPERATURES

Media for the test may be prepared as described below, or equivalent commercial media may be used provided that they comply with the growth promotion test.

The following culture media have been found to be suitable for the test for sterility. Fluid thioglycollate medium is primarily intended for the culture of anaerobic bacteria; however, it will also detect aerobic bacteria. Soya-bean casein digest medium is suitable for the culture of both fungi and aerobic bacteria.

Other media may be used provided that they pass the growth promotion and the validation tests.

Fluid thioglycollate medium

L-Cystine	0.5 g
Agar, granulated (moisture content not in excess of 15 per cent)	0.75 g
Sodium chloride	2.5 g
Glucose monohydrate/anhydrous	5.5 g/5.0 g
Yeast extract (water-soluble)	5.0 g
Pancreatic digest of casein	15.0 g
Sodium thioglycollate or	0.5 g
Thioglycollic acid	0.3 ml
Resazurin sodium solution (1 g/l of resazurin sodium), freshly prepared	1.0 ml
Water R	1000 ml

pH of the medium after sterilisation 7.1 ± 0.2

Mix the L-cystine, agar, sodium chloride, glucose, water-soluble yeast extract and pancreatic digest of casein with the *water R* and heat until solution is effected. Dissolve the sodium thioglycollate or thioglycollic acid in the solution and, if necessary, add *1 M sodium hydroxide* so that, after sterilisation, the solution will have a pH of 7.1 ± 0.2. If filtration is necessary, heat the solution again without boiling and filter while hot through moistened filter paper. Add the resazurin sodium solution, mix and place the medium in suitable vessels which provide a ratio of surface to depth of medium such that not more than the upper half of the medium has undergone a colour change indicative of oxygen uptake at the end of the incubation period. Sterilise using a validated process. If the medium is stored, store at 2-25 °C in a sterile, airtight container. If more than the upper third of the medium has acquired a pink colour, the medium may be restored once by heating the containers in a water-bath or in free-flowing steam until the pink colour disappears and cooling quickly, taking care to prevent the introduction of non-sterile air into the container. Do not use the medium for a longer storage period than has been validated.

Fluid thioglycollate medium is to be incubated at 30-35 °C.

Soya-bean casein digest medium

Pancreatic digest of casein	17.0 g
Papaic digest of soya-bean meal	3.0 g
Sodium chloride	5.0 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate/anhydrous	2.5 g/2.3 g
Water R	1000 ml

pH of the medium after sterilisation 7.3 ± 0.2

Dissolve the solids in *water R*, warming slightly to effect solution. Cool the solution to room temperature. Add *1 M sodium hydroxide*, if necessary, so that after sterilisation the medium will have a pH of 7.3 ± 0.2. Filter, if necessary, to clarify, distribute into suitable vessels and sterilise using a validated process. Store at 2-25 °C in a sterile well-closed container, unless it is intended for immediate use. Do not use the medium for a longer storage period than has been validated.

Soya-bean casein digest medium is to be incubated at 20-25 °C.

The media used comply with the following tests, carried out before or in parallel with the test on the product to be examined.

Sterility. Incubate portions of the media for 14 days. No growth of micro-organisms occurs.

Growth promotion test of aerobes, anaerobes and fungi. Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from the ingredients. Suitable strains of micro-organisms are indicated in Table 2.6.1.-1.

Inoculate portions of fluid thioglycollate medium with a small number (not more than 100 CFU) of the following micro-organisms, using a separate portion of medium for each of the following species of micro-organism: *Clostridium sporogenes, Pseudomonas aeruginosa, Staphylococcus aureus.* Inoculate portions of soya-bean casein digest medium with a small number (not more than 100 CFU) of the following micro-organisms, using a separate portion of medium for each of the following species of micro-organism: *Aspergillus niger, Bacillus subtilis, Candida albicans.* Incubate for not more than 3 days in the case of bacteria and not more than 5 days in the case of fungi.

Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

The media are suitable if a clearly visible growth of the micro-organisms occurs.

VALIDATION TEST

Carry out a test as described below under Test for sterility of the product to be examined using exactly the same methods except for the following modifications.

Membrane filtration. After transferring the contents of the container or containers to be tested to the membrane add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the final portion of sterile diluent used to rinse the filter.

Direct inoculation. After transferring the contents of the container or containers to be tested (for catgut and other surgical sutures for veterinary use: strands) to the culture medium add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the medium.

In both cases use the same micro-organisms as those described above under Growth promotion test of aerobes, anaerobes and fungi. Perform a growth promotion test as a positive control. Incubate all the containers containing medium for not more than 5 days.

If clearly visible growth of micro-organisms is obtained after the incubation, visually comparable to that in the control vessel without product, either the product possesses no antimicrobial activity under the conditions of the test or such activity has been satisfactorily eliminated. The test for sterility may then be carried out without further modification.

If clearly visible growth is not obtained in the presence of the product to be tested, visually comparable to that in the control vessels without product, the product possesses antimicrobial activity that has not been satisfactorily eliminated under the conditions of the test. Modify the conditions in order to eliminate the antimicrobial activity and repeat the validation test.

This validation is performed:

a) when the test for sterility has to be carried out on a new product,

b) whenever there is a change in the experimental conditions of the test.

The validation may be performed simultaneously with the test for sterility of the product to be examined.

TEST FOR STERILITY OF THE PRODUCT TO BE EXAMINED

The test may be carried out using the technique of membrane filtration or by direct inoculation of the culture media with the product to be examined. Appropriate negative controls are included. The technique of membrane filtration is used whenever the nature of the product permits, that is, for filterable aqueous preparations, for alcoholic or oily preparations and for preparations miscible with or soluble in aqueous or oily solvents provided these solvents do not have an antimicrobial effect in the conditions of the test.

Membrane filtration. Use membrane filters having a nominal pore size not greater than 0.45 µm whose effectiveness to retain micro-organisms has been established. Cellulose nitrate filters, for example, are used for aqueous, oily and weakly alcoholic solutions and cellulose acetate filters, for example, for strongly alcoholic solutions. Specially adapted filters may be needed for certain products, e.g. for antibiotics.

The technique described below assumes that membranes about 50 mm in diameter will be used. If filters of a different diameter are used the volumes of the dilutions and the washings should be adjusted accordingly. The filtration apparatus and membrane are sterilised by appropriate means. The apparatus is designed so that the solution to be examined can be introduced and filtered under aseptic conditions; it permits the aseptic removal of the membrane for transfer to the medium or it is suitable for carrying out the incubation after adding the medium to the apparatus itself.

Aqueous solutions. If appropriate, transfer a small quantity of a suitable, sterile diluent such as a 1 g/l neutral solution of meat or casein peptone pH 7.1 ± 0.2 onto the membrane in the apparatus and filter. The diluent may contain suitable neutralising substances and/or appropriate inactivating substances for example in the case of antibiotics.

Transfer the contents of the container or containers to be tested to the membrane or membranes, if necessary after diluting to the volume used in the validation test with the chosen sterile diluent but in any case using not less than the quantities of the product to be examined prescribed in Table 2.6.1.-2. Filter immediately. If the product has antimicrobial properties, wash the membrane not less than 3 times by filtering through it each time the volume of the chosen sterile diluent used in the validation test. Do not exceed a washing cycle of 5 times 200 ml, even if during validation it has been demonstrated that such a cycle does not fully eliminate the antimicrobial activity. Transfer the whole membrane to the culture medium or cut it aseptically into 2 equal parts and transfer one half to each of 2 suitable media. Use the same volume of each medium as in the validation test. Alternatively, transfer the medium onto the membrane in the apparatus. Incubate the media for not less than 14 days.

Soluble solids. Use for each medium not less than the quantity prescribed in Table 2.6.1.-2 of the product dissolved in a suitable solvent such as a 1 g/l neutral solution of meat or casein peptone and proceed with the test as described above for aqueous solutions using a membrane appropriate to the chosen solvent.

Oils and oily solutions. Use for each medium not less than the quantity of the product prescribed in Table 2.6.1.-2. Oils and oily solutions of sufficiently low viscosity may be filtered without dilution through a dry membrane. Viscous oils may be diluted as necessary with a suitable sterile diluent such as

Table 2.6.1.-1 – *Strains of the test micro-organisms suitable for use in the Growth Promotion Test and the Validation Test*

Aerobic bacteria	
Staphylococcus aureus	ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518
Bacillus subtilis	ATCC 6633, CIP 52.62, NCIMB 8054
Pseudomonas aeruginosa	ATCC 9027, NCIMB 8626, CIP 82.118
Anaerobic bacterium	
Clostridium sporogenes	ATCC 19404, CIP 79.3, NCTC 532 *or* ATCC 11437
Fungi	
Candida albicans	ATCC 10231, IP 48.72, NCPF 3179
Aspergillus niger	ATCC 16404, IP 1431.83, IMI 149007

Table 2.6.1.-2 – *Minimum quantity to be used for each medium*

Quantity per container	Minimum quantity to be used for each medium unless otherwise justified and authorised
Liquids	
– less than 1 ml	The whole contents of each container
– 1-40 ml	Half the contents of each container but not less than 1 ml
– greater than 40 ml and not greater than 100 ml	20 ml
– greater than 100 ml	10 per cent of the contents of the container but not less than 20 ml
Antibiotic liquids	1 ml
Other preparations soluble in water or in isopropyl myristate	The whole contents of each container to provide not less than 200 mg
Insoluble preparations, creams and ointments to be suspended or emulsified	The whole contents of each container to provide not less than 200 mg
Solids	
– less than 50 mg	The whole contents of each container
– 50 mg or more but less than 300 mg	Half the contents of each container but not less than 50 mg
– 300 mg to 5 g	150 mg
– greater than 5 g	500 mg
Catgut and other surgical sutures for veterinary use	3 sections of a strand (each 30 cm long)

isopropyl myristate shown not to have antimicrobial activity in the conditions of the test. Allow the oil to penetrate the membrane by its own weight then filter, applying the pressure or suction gradually. Wash the membrane at least 3 times by filtering through it each time about 100 ml of a suitable sterile solution such as 1 g/l neutral meat or casein peptone containing a suitable emulsifying agent at a concentration shown to be appropriate in the validation of the test, for example polysorbate 80 at a concentration of 10 g/l. Transfer the membrane or membranes to the culture medium or media or vice versa as described above for aqueous solutions, and incubate at the same temperatures and for the same times.

Ointments and creams. Use for each medium not less than the quantities of the product prescribed in Table 2.6.1.-2. Ointments in a fatty base and emulsions of the water-in-oil type may be diluted to 1 per cent in isopropyl myristate as described above, by heating, if necessary, to not more than 40 °C. In exceptional cases it may be necessary to heat to not more than 44 °C. Filter as rapidly as possible and proceed as described above for oils and oily solutions.

Direct inoculation of the culture medium. Transfer the quantity of the preparation to be examined prescribed in Table 2.6.1.-2 directly into the culture medium so that the volume of the product is not more than 10 per cent of the volume of the medium, unless otherwise prescribed.

If the product to be examined has antimicrobial activity, carry out the test after neutralising this with a suitable neutralising substance or by dilution in a sufficient quantity of culture medium. When it is necessary to use a large volume of the product it may be preferable to use a concentrated culture medium prepared in such a way that it takes account of the subsequent dilution. Where appropriate, the concentrated medium may be added directly to the product in its container.

Oily liquids. Use media to which have been added a suitable emulsifying agent at a concentration shown to be appropriate in the validation of the test, for example polysorbate 80 at a concentration of 10 g/l.

Ointments and creams. Prepare by diluting to about 1 in 10 by emulsifying with the chosen emulsifying agent in a suitable sterile diluent such as a 1 g/l neutral solution of meat or casein peptone. Transfer the diluted product to a medium not containing an emulsifying agent.

Incubate the inoculated media for not less than 14 days. Observe the cultures several times during the incubation period. Shake cultures containing oily products gently each day. However when thioglycollate medium or other similar medium is used for the detection of anaerobic micro-organisms keep shaking or mixing to a minimum in order to maintain anaerobic conditions.

Catgut and other surgical sutures for veterinary use. Use for each medium not less than the quantities of the product prescribed in Table 2.6.1.-2. Open the sealed package using aseptic precautions and remove 3 sections of the strand for each culture medium. Carry out the test on 3 sections, each 30 cm long, cut off from the beginning, the centre and the end of the strand. Use whole strands from freshly opened cassette packs. Transfer each section of the strand to the selected medium. Use sufficient medium to cover adequately the material to be tested (20 ml to 150 ml).

OBSERVATION AND INTERPRETATION OF RESULTS

At intervals during the incubation period and at its conclusion, examine the media for macroscopic evidence of microbial growth. If the material being tested renders the medium turbid so that the presence or absence of microbial growth cannot be readily determined by visual examination, 14 days after the beginning of incubation transfer portions (each not less than 1 ml) of the medium to fresh vessels of the same medium and then incubate the original and transfer vessels for not less than 4 days.

If no evidence of microbial growth is found, the product to be examined complies with the test for sterility. If evidence of microbial growth is found the product to be examined does not comply with the test for sterility, unless it can be clearly demonstrated that the test was invalid for causes unrelated to the product to be examined. The test may be considered invalid only if one or more of the following conditions are fulfilled:

a) the data of the microbiological monitoring of the sterility testing facility show a fault,

b) a review of the testing procedure used during the test in question reveals a fault,

c) microbial growth is found in the negative controls,

d) after determination of the identity of the micro-organisms isolated from the test, the growth of this species or these species may be ascribed unequivocally to faults with respect to the material and/or the technique used in conducting the sterility test procedure.

If the test is declared to be invalid it is repeated with the same number of units as in the original test.

If no evidence of microbial growth is found in the repeat test the product examined complies with the test for sterility. If microbial growth is found in the repeat test the product examined does not comply with the test for sterility.

APPLICATION OF THE TEST TO PARENTERAL PREPARATIONS, OPHTHALMIC AND OTHER NON-INJECTABLE PREPARATIONS REQUIRED TO COMPLY WITH THE TEST FOR STERILITY

When using the technique of membrane filtration, use, whenever possible, the whole contents of the container, but not less than the quantities indicated in Table 2.6.1.-2, diluting where necessary to about 100 ml with a suitable sterile solution, such as 1 g/l neutral meat or casein peptone.

When using the technique of direct inoculation of media, use the quantities shown in Table 2.6.1.-2, unless otherwise justified and authorised. The tests for bacterial and fungal sterility are carried out on the same sample of the product to be examined. When the volume or the quantity in a single container is insufficient to carry out the tests, the contents of 2 or more containers are used to inoculate the different media.

GUIDELINES FOR USING THE TEST FOR STERILITY

The purpose of the test for sterility, as that of all pharmacopoeial tests, is to provide an independent control analyst with the means of verifying that a particular material meets the requirements of the European Pharmacopoeia. A manufacturer is neither obliged to carry out such tests nor precluded from using modifications of, or alternatives to, the stated method, provided he is satisfied that, if tested by the official method, the material in question would comply with the requirements of the European Pharmacopoeia.

Precautions against microbial contamination. Aseptic conditions for performance of the test can be achieved using, for example, a class A laminar-air-flow cabinet located within a class B clean-room, or an isolator.

Guidance to manufacturers. The level of assurance provided by a satisfactory result of a test for sterility (the absence of contaminated units in the sample) as applied to the quality of the batch is a function of the homogeneity of the batch, the conditions of manufacture and the efficiency of the adopted sampling plan. Hence for the purpose of this text a batch is defined as a homogeneous collection of sealed containers prepared in such a manner that the risk of contamination is the same for each of the units contained therein.

In the case of terminally sterilised products, physical proofs, biologically based and automatically documented, showing correct treatment throughout the batch during sterilisation are of greater assurance than the sterility test. The circumstances in which parametric release may be considered appropriate are described under Methods of preparation of sterile products (*5.1.1*). The method of media-fill runs may be used to evaluate the process of aseptic production. Apart from that the sterility test is the only analytical method available for products prepared under aseptic conditions and furthermore it is, in all cases, the only analytical method available to the authorities who have to examine a specimen of a product for sterility.

The probability of detecting micro-organisms by the test for sterility increases with their number present in the sample tested and varies according to the readiness of growth of micro-organism present. The probability of detecting very low levels of contamination even when it is homogenous throughout the batch is very low. The interpretation of the results of the test for sterility rests on the assumption that the contents of every container in the batch, had they been tested, would have given the same result. Since it is manifest that every container cannot be tested, an appropriate sampling plan should be adopted. In the case of aseptic production, it is recommended to include samples filled at the beginning and at the end of the batch and after significant intervention.

Table 2.6.1.-3. — *Minimum number of items to be tested*

Number of items in the batch	Minimum number of items to be tested for each medium, unless otherwise justified and authorised*
Parenteral preparations	
— Not more than 100 containers	10 per cent or 4 containers, whichever is the greater
— More than 100 but not more than 500 containers	10 containers
— More than 500 containers	2 per cent or 20 containers, whichever is less
Ophthalmic and other non-injectable preparations	
— Not more than 200 containers	5 per cent or 2 containers, whichever is the greater
— More than 200 containers	10 containers
— If the product is presented in the form of single-dose containers, apply the scheme shown above for preparations for parenteral use	
Catgut and other surgical sutures for veterinary use	2 per cent or 5 packages whichever is the greater, up to a maximum total of 20 packages
Bulk solid products	
— Up to 4 containers	Each container
— More than 4 containers but not more than 50 containers	20 per cent or 4 containers, whichever is the greater
— More than 50 containers	2 per cent or 10 containers, whichever is the greater
Pharmacy bulk packages of antibiotics (greater than 5 g)	6 containers
*If the contents of one container are enough to inoculate the two media, this column gives the number of containers needed for both the media together.	

Guidance on the minimum number of items recommended to be tested in relation to the size of the batch is given in Table 2.6.1.-3. The application of the recommendations must have regard to the volume of preparation per container, to the validation of the sterilisation method and to any other special considerations concerning the intended sterility of the product.

Observation and interpretation of results. Conventional microbiological/biochemical techniques are generally satisfactory for identification of micro-organisms recovered from a sterility test. However, if a manufacturer wishes to use condition (d) as the sole criterion for invalidating a sterility test, it may be necessary to employ sensitive typing techniques to demonstrate that a micro-organism isolated from the product test is identical to a micro-organism isolated from the test materials and/or the testing environment. While routine microbiological/biochemical identification techniques can demonstrate that 2 isolates are not identical, these methods may not be sufficiently sensitive or reliable enough to provide unequivocal evidence that two isolates are from the same source. More sensitive tests, for example, molecular typing with RNA/DNA homology, may be necessary to determine that micro-organisms are clonally related and have a common origin.

01/2008:20602

2.6.2. MYCOBACTERIA

If the sample to be examined may be contaminated by micro-organisms other than mycobacteria, treat it with a suitable decontamination solution, such as acetylcysteine-sodium hydroxide solution or sodium laurilsulfate solution.

Inoculate 0.2 ml of the sample in triplicate onto each of 2 suitable solid media (Löwenstein-Jensen medium and Middlebrook 7H10 medium are considered suitable). Inoculate 0.5 ml in triplicate into a suitable liquid medium. Incubate all media at 37 °C for 56 days.

Establish the fertility of the media in the presence of the preparation to be examined by inoculation of a suitable strain of a *Mycobacterium* sp. such as BCG and if necessary use a suitable neutralising substance.

If contaminating micro-organisms develop during the first 8 days of incubation, repeat the test and carry out at the same time a bacteriological sterility test.

If at the end of the incubation time no growth of mycobacteria occurs in any of the test media, the preparation complies with the test.

01/2008:20607

2.6.7. MYCOPLASMAS

Where the test for mycoplasmas is prescribed for a master cell bank, for a working cell bank, for a virus seed lot or for control cells, both the culture method and the indicator cell culture method are used. Where the test for mycoplasmas is prescribed for a virus harvest, for a bulk vaccine or for the final lot (batch), the culture method is used. The indicator cell culture method may also be used, where necessary, for screening of media.

Nucleic acid amplification techniques (NAT) may be used as an alternative to one or both of the other methods after suitable validation.

CULTURE METHOD

CHOICE OF CULTURE MEDIA

The test is carried out using a sufficient number of both solid and liquid media to ensure growth in the chosen incubation conditions of small numbers of mycoplasmas that may be present in the product to be examined. Liquid media must contain phenol red. The range of media chosen is shown to have satisfactory nutritive properties for at least the micro-organisms shown below. The nutritive properties of each new batch of medium are verified for the appropriate micro-organisms in the list. When testing for mycoplasmas in the product to be examined, at least 1 of the following species will be included as a positive control:

- *Acholeplasma laidlawii* (vaccines for human and veterinary use where an antibiotic has been used during production);
- *Mycoplasma gallisepticum* (where avian material has been used during production or where the vaccine is intended for use in poultry);
- *Mycoplasma hyorhinis* (non-avian veterinary vaccines);
- *Mycoplasma orale* (vaccines for human and veterinary use);
- *Mycoplasma pneumoniae* (vaccines for human use) or other suitable species of D-glucose fermenter such as *Mycoplasma fermentans*;
- *Mycoplasma synoviae* (where avian material has been used during production or where the vaccine is intended for use in poultry).

The test strains are field isolates having undergone a limited number of subcultures (not more than 15), and are stored frozen or freeze-dried. After cloning, the strains are identified as being of the required species by comparison with type cultures, for example:

A. laidlawii	NCTC 10116	CIP 75.27	ATCC 23206
M. gallisepticum	NCTC 10115	CIP 104967	ATCC 19610
M. fermentans	NCTC 10117	CIP 105680	ATCC 19989
M. hyorhinis	NCTC 10130	CIP 104968	ATCC 17981
M. orale	NCTC 10112	CIP 104969	ATCC 23714
M. pneumoniae	NCTC 10119	CIP 103766	ATCC 15531
M. synoviae	NCTC 10124	CIP 104970	ATCC 25204

Acholeplasma laidlawii BRP, Mycoplasma fermentans BRP, Mycoplasma hyorhinis BRP, Mycoplasma orale BRP and *Mycoplasma synoviae BRP* are suitable for use as low-passage reference strains.

INCUBATION CONDITIONS

Incubate liquid media in tightly stoppered containers at 35-38 °C. Incubate solid media in microaerophilic conditions (nitrogen containing 5-10 per cent of carbon dioxide and sufficient humidity to prevent desiccation of the agar surface) at 35-38 °C.

NUTRITIVE PROPERTIES

Carry out the test for nutritive properties for each new batch of medium. Inoculate the chosen media with the appropriate test micro-organisms; use not more than 100 CFU (colony-forming units) per 60 mm diameter plate containing 9 ml of solid medium and per 100 ml container of liquid medium; use a separate plate and container for each species of micro-organism. Incubate the media and make subcultures from 0.2 ml of liquid medium to solid medium at the specified intervals (see below under Test for mycoplasmas in the product to be examined). The solid medium complies with the test if adequate growth is found for each test

micro-organism (growth obtained does not differ by a factor greater than 5 from the value calculated with respect to the inoculum). The liquid medium complies with the test if growth on agar plates subcultured from the broth is found for at least 1 subculture for each test micro-organism.

INHIBITORY SUBSTANCES

The test for inhibitory substances is carried out once for a given product and is repeated whenever there is a change in production method that may affect the detection of mycoplasmas.

To demonstrate absence of inhibitory substances, carry out the test for nutritive properties in the presence and absence of the product to be examined. If growth of a test micro-organism occurs more than 1 subculture sooner in the absence of the product to be examined than in its presence, or if plates directly inoculated with the product to be examined have fewer than 1/5 of the number of colonies of those inoculated without the product to be examined, inhibitory substances are present and they must be neutralised or their effect otherwise countered, for example by passage in substrates not containing inhibitors or dilution in a larger volume of medium before the test. If dilution is used, larger medium volumes may be used or the inoculum volume may be divided among several 100 ml flasks. The effectiveness of the neutralisation or other process is checked by repeating the test for inhibitory substances after neutralisation.

TEST FOR MYCOPLASMAS IN THE PRODUCT TO BE EXAMINED

Inoculate 10 ml of the product to be examined per 100 ml of each liquid medium. If it has been found that a significant pH change occurs upon the addition of the product to be examined, the liquid medium is restored to its original pH value by the addition of a solution of either sodium hydroxide or hydrochloric acid. Inoculate 0.2 ml of the product to be examined on each plate of each solid medium. Incubate liquid media for 20-21 days. Incubate solid media for not less than 14 days, except those corresponding to the 20-21 day subculture, which are incubated for 7 days. At the same time incubate an uninoculated 100 ml portion of each liquid medium and agar plates, as a negative control. On days 2-4 after inoculation, subculture each liquid medium by inoculating 0.2 ml on at least 1 plate of each solid medium. Repeat the procedure between the 6^{th} and 8^{th} days, again between the 13^{th} and 15^{th} days and again between the 19^{th} and 21^{st} days of the test. Observe the liquid media every 2 or 3 days and if a colour change occurs, subculture. If a liquid medium shows bacterial or fungal contamination, the test is invalid. The test is valid if at least 1 plate per medium and per inoculation day can be read. Include in the test positive controls prepared by inoculation of not more than 100 CFU of at least 1 test micro-organism on agar medium or into broth medium. Where the test for mycoplasmas is carried out regularly and where possible, it is recommended to use the test micro-organisms in regular rotation. The test micro-organisms used are those listed under Choice of culture media.

INTERPRETATION OF RESULTS

At the end of the prescribed incubation period, examine all inoculated solid media microscopically for the presence of mycoplasma colonies. The product complies with the test if growth of typical mycoplasma colonies has not occurred. The product does not comply with the test if growth of typical mycoplasma colonies has occurred on any of the solid media. The test is invalid if 1 or more of the positive controls do not show growth of mycoplasmas on at least 1 subculture plate. The test is invalid if 1 or more of the negative controls show growth of mycoplasmas. If suspect colonies are observed, a suitable validated method may be used to determine whether they are due to mycoplasmas.

The following section is published for information.

RECOMMENDED MEDIA FOR THE CULTURE METHOD

The following media are recommended. Other media may be used, provided that their ability to sustain the growth of mycoplasmas has been demonstrated on each batch in the presence and absence of the product to be examined.

HAYFLICK MEDIA (RECOMMENDED FOR THE GENERAL DETECTION OF MYCOPLASMAS)

Liquid medium

Beef heart infusion broth (1)	90.0 ml
Horse serum (unheated)	20.0 ml
Yeast extract (250 g/l)	10.0 ml
Phenol red (0.6 g/l solution)	5.0 ml
Penicillin (20 000 IU/ml)	0.25 ml
Deoxyribonucleic acid (2 g/l solution)	1.2 ml

Adjust to pH 7.8.

Solid medium

Prepare as described above replacing beef heart infusion broth by beef heart infusion agar containing 15 g/l of agar.

FREY MEDIA (RECOMMENDED FOR THE DETECTION OF M. SYNOVIAE)

Liquid medium

Beef heart infusion broth (1)	90.0 ml
Essential vitamins (2)	0.025 ml
Glucose monohydrate (500 g/l solution)	2.0 ml
Swine serum (inactivated at 56 °C for 30 min)	12.0 ml
β-Nicotinamide adenine dinucleotide (10 g/l solution)	1.0 ml
Cysteine hydrochloride (10 g/l solution)	1.0 ml
Phenol red (0.6 g/l solution)	5.0 ml
Penicillin (20 000 IU/ml)	0.25 ml

Mix the solutions of β-nicotinamide adenine dinucleotide and cysteine hydrochloride and after 10 min add to the other ingredients. Adjust to pH 7.8.

Solid medium

Beef heart infusion broth (1)	90.0 ml
Agar, purified (3)	1.4 g

Adjust to pH 7.8, sterilise by autoclaving then add:

Essential vitamins (2)	0.025 ml
Glucose monohydrate (500 g/l solution)	2.0 ml
Swine serum (unheated)	12.0 ml
β-Nicotinamide adenine dinucleotide (10 g/l solution)	1.0 ml
Cysteine hydrochloride (10 g/l solution)	1.0 ml
Phenol red (0.6 g/l solution)	5.0 ml
Penicillin (20 000 IU/ml)	0.25 ml

FRIIS MEDIA (RECOMMENDED FOR THE DETECTION OF NON-AVIAN MYCOPLASMAS)

Liquid medium

Hanks' balanced salt solution (modified) (4)	800 ml
Distilled water	67 ml
Brain heart infusion (5)	135 ml
PPLO Broth (6)	248 ml
Yeast extract (170 g/l)	60 ml
Bacitracin	250 mg
Meticillin	250 mg
Phenol red (5 g/l)	4.5 ml
Horse serum	165 ml
Swine serum	165 ml

Adjust to pH 7.40-7.45.

Solid medium

Hanks' balanced salt solution (modified) (4)	200 ml
DEAE-dextran	200 mg
Agar, purified (3)	15.65 g

Mix well and sterilise by autoclaving. Cool to 100 °C. Add to 1740 ml of liquid medium as described above.

(1) *Beef heart infusion broth*

Beef heart (for preparation of the infusion)	500 g
Peptone	10 g
Sodium chloride	5 g
Distilled water	to 1000 ml

Sterilise by autoclaving.

(2) *Essential vitamins*

Biotin	100 mg
Calcium pantothenate	100 mg
Choline chloride	100 mg
Folic acid	100 mg
i-Inositol	200 mg
Nicotinamide	100 mg
Pyridoxal hydrochloride	100 mg
Riboflavine	10 mg
Thiamine hydrochloride	100 mg
Distilled water	to 1000 ml

(3) *Agar, purified*

A highly refined agar for use in microbiology and immunology, prepared by an ion-exchange procedure that results in a product having superior purity, clarity and gel strength. It contains about:

Water	12.2 per cent
Ash	1.5 per cent
Acid-insoluble ash	0.2 per cent
Chlorine	0
Phosphate (calculated as P_2O_5)	0.3 per cent
Total nitrogen	0.3 per cent
Copper	8 ppm
Iron	170 ppm
Calcium	0.28 per cent
Magnesium	0.32 per cent

(4) *Hanks' balanced salt solution (modified)*

Sodium chloride	6.4 g
Potassium chloride	0.32 g
Magnesium sulphate heptahydrate	0.08 g
Magnesium chloride hexahydrate	0.08 g
Calcium chloride, anhydrous	0.112 g
Disodium hydrogen phosphate dihydrate	0.0596 g
Potassium dihydrogen phosphate, anhydrous	0.048 g
Distilled water	to 800 ml

(5) *Brain heart infusion*

Calf-brain infusion	200 g
Beef-heart infusion	250 g
Proteose peptone	10 g
Glucose monohydrate	2 g
Sodium chloride	5 g
Disodium hydrogen phosphate, anhydrous	2.5 g
Distilled water	to 1000 ml

(6) *PPLO broth*

Beef-heart infusion	50 g
Peptone	10 g
Sodium chloride	5 g
Distilled water	to 1000 ml

INDICATOR CELL CULTURE METHOD

Cell cultures are stained with a fluorescent dye that binds to DNA. Mycoplasmas are detected by their characteristic particulate or filamentous pattern of fluorescence on the cell surface and, if contamination is heavy, in surrounding areas. Mitochondria in the cytoplasm may be stained but are readily distinguished from mycoplasmas.

If for viral suspensions the interpretation of results is affected by marked cytopathic effects, the virus may be neutralised using a specific antiserum that has no inhibitory effects on mycoplasmas or a cell culture substrate that does not allow growth of the virus may be used. To demonstrate the absence of inhibitory effects of serum, carry out the positive control tests in the presence and absence of the antiserum.

VERIFICATION OF THE SUBSTRATE

Use Vero cells or another cell culture (for example, the production cell line) that is equivalent in effectiveness for detecting mycoplasmas. Test the effectiveness of the cells to be used by applying the procedure shown below and inoculating not more than 100 CFU or CFU-like micro-organisms of suitable reference strains of *M. hyorhinis* and *M. orale*. The following strains have been found to be suitable:

M. hyorhinis			ATCC 29052
M. orale	NCTC 10112	CIP 104969	ATCC 23714

The cells are suitable if both reference strains are detected.

The indicator cells must be subcultured without an antibiotic before use in the test.

TEST METHOD

1. Seed the indicator cell culture at a suitable density (for example, 2×10^4 to 2×10^5 cells/ml, 4×10^3 to 2.5×10^4 cells/cm^2) that will yield confluence after 3 days of growth. Inoculate 1 ml of the product to be examined into the cell culture vessel and incubate at 35-38 °C.

2. After at least 3 days of incubation, when the cells have grown to confluence, make a subculture on cover slips in suitable containers or on some other surface (for example, chambered slides) suitable for the test procedure. Seed the cells at low density so that they reach 50 per cent confluence after 3-5 days of incubation. Complete confluence impairs visualisation of mycoplasmas after staining and must be avoided.

3. Remove the medium and rinse the indicator cells with *phosphate buffered saline pH 7.4 R*, then add a suitable fixing solution (a freshly prepared mixture of 1 volume of *glacial acetic acid R* and 3 volumes of *methanol R* is suitable when *bisbenzimide R* is used for staining).

4. Remove the fixing solution and wash the cells with sterile *water R*. Dry the slides completely if they are to be stained more than 1 h later (particular care is needed for staining of slides after drying owing to artefacts that may be produced).

5. Add a suitable DNA stain and allow to stand for a suitable time (*bisbenzimide working solution R* and a standing time of 10 min are suitable).

6. Remove the stain and rinse the monolayer with *water R*.

7. Mount each coverslip, where applicable (a mixture of equal volumes of *glycerol R* and *phosphate-citrate buffer solution pH 5.5 R* is suitable for mounting). Examine by fluorescence (for bisbenzimide stain a 330 nm/380 nm excitation filter and an LP 440 nm barrier filter are suitable) at 400 × magnification or greater.

8. Compare the microscopic appearance of the test cultures with that of the negative and positive controls, examining for extranuclear fluorescence. Mycoplasmas produce pinpoints or filaments over the indicator cell cytoplasm. They may also produce pinpoints and filaments in the intercellular spaces. Multiple microscopic fields are examined according to the protocol established during validation.

INTERPRETATION OF RESULTS

The product to be examined complies with the test if fluorescence typical of mycoplasmas is not present. The test is invalid if the positive controls do not show fluorescence typical of mycoplasmas. The test is invalid if the negative controls show fluorescence typical of mycoplasmas.

NUCLEIC ACID AMPLIFICATION TECHNIQUES (NAT)

NAT (*2.6.21*) may be used for detection of mycoplasmas by amplification of nucleic acids extracted from a test sample with specific primers that reveal the presence of the target nucleic acid. NAT indicate the presence of a particular nucleic acid sequence and not necessarily the presence of viable mycoplasmas. A number of different techniques are available. This general chapter does not prescribe a particular method for the test. The procedure applied must be validated as described, taking account of the guidelines presented at the end of this section. Where a commercial kit is used, certain elements of the validation may be carried out by the manufacturer and information provided to the user but it must be remembered that full information on the primers may not be available and that production of the kit may be modified or discontinued.

NAT are applied where prescribed in a monograph. They may also be used instead of the culture method and the indicator cell culture method after suitable validation.

Direct NAT can be applied in the presence of cytotoxic material and where a rapid method is needed.

Cell-culture enrichment followed by NAT: the test sample and a suitable cell substrate (as described under the indicator cell-culture method) are cultured together for a suitable period; the nucleic acids are then extracted from cells and supernatant and used for detection by NAT.

VALIDATION

Reference standards are required at various stages during validation and for use as controls during routine application of the test. The reference standards may be mycoplasmas or nucleic acids.

For validation of the limit of detection, the following species represent an optimal selection in terms of the frequency of occurrence as contaminants and phylogenetic relationships:

- *A. laidlawii*;
- *M. fermentans*;
- *M. hyorhinis* (where cell-culture enrichment is used, a fastidious strain such as ATCC 29052 is included);
- *M. orale*;
- *M. pneumoniae* or *M. gallisepticum*;
- *M. synoviae* (where there is use of or exposure to avian material during production);
- *Mycoplasma arginini;*
- *Spiroplasma citri* (where there is use of or exposure to insect or plant material during production).

Demonstration of specificity requires the use of a suitable range of bacterial species other than mycoplasmas. Bacterial genera with close phylogenetic relation to mycoplasmas are most appropriate for this validation; these include *Clostridium, Lactobacillus* and *Streptococcus*.

Comparability studies for use of NAT as an alternative method. For each mycoplasma test species:

- as an alternative to the culture method: the NAT test system must be shown to detect 10 CFU/ml;
- as an alternative to the indicator cell culture method: the NAT test system must be shown to detect 100 CFU/ml;

or an equivalent limit of detection in terms of the number of copies of mycoplasma nucleic acid in the test sample (using suitable reference standards of mycoplasma nucleic acid).

CONTROLS

Internal controls. Internal controls are necessary for routine verification of absence of inhibition. The internal control may contain the primer binding-site, or some other suitable sequence may be used. It is preferably added to the test material before isolating the nucleic acid and therefore acts as an overall control (extraction, reverse transcription, amplification, detection).

External controls. The external positive control contains a defined number of target-sequence copies or CFUs from 1 or more suitable species of mycoplasma chosen from those used during validation of the test conditions. 1 of the positive controls is set close to the positive cut-off point to demonstrate that the expected sensitivity is achieved. The external negative control contains no target sequence but does not necessarily represent the same matrix as the test article.

INTERPRETATION OF RESULTS

The primers used may also amplify non-mycoplasmal bacterial nucleic acid, leading to false positive results. Procedures are established at the time of validation for dealing with confirmation of positive results, where necessary.

The following section is published for information.

Validation of nucleic acid amplification techniques (nat) for the detection of mycoplasmas: guidelines

1. *SCOPE*

Nucleic acid amplification techniques (NAT) are either qualitative or quantitative tests for the presence of nucleic acid. For the detection of mycoplasma contamination of various samples such as vaccines and cell substrates, qualitative tests are adequate and may be considered to be limit tests.

These guidelines describe methods to validate qualitative nucleic acid amplification analytical procedures for assessing mycoplasma contamination. They may also be applicable for real-time NAT used as limit tests for the control of contaminants.

The 2 characteristics regarded as the most important for validation of the analytical procedure are the specificity and the detection limit. In addition, the robustness of the analytical procedure should be evaluated.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part or all of the analytical procedure, documented validation points already covered by the kit manufacturer can replace validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. detection limit, robustness, cross-detection of other classes of bacteria).

NAT may be used as:

- a complementary test (for example, for cytotoxic viral suspensions) or for in-process control purposes;
- an alternative method to replace an official method (indicator cell culture method or culture method).

These guidelines will thus separate these 2 objectives by presenting first a guideline for the validation of the NAT themselves, and second, a guideline for a comparability study between NAT and official methods.

2. *GUIDELINE FOR MYCOPLASMA NAT VALIDATION*

3 parameters should be evaluated: specificity, detection limit and robustness.

2-1. **Specificity**. Specificity is the ability to unequivocally assess target nucleic acid in the presence of components that may be expected to be present.

The specificity of NAT is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and detection steps).

The ability of the NAT to detect a large panel of mycoplasma species will depend on the choice of primers, probes and method parameters. This ability should be demonstrated using characterised reference panels (e.g. reference strains provided by the EDQM). Since NAT systems are usually based on a mix of primers, the theoretical analysis of primers and probes by comparison with databases is not recommended, because interpretation of the results may be quite complex and may not reflect the experimental results.

Moreover, as it is likely that the primers will detect other bacterial species, the potential cross-detection should be documented in the validation study. Bacterial genera such as gram-positive bacteria with close phylogenetic relation to mycoplasmas are most appropriate for this validation; these include *Clostridium*, *Lactobacillus* and *Streptococcus*. However, this is not an exhaustive list and species to be tested will depend on the theoretical ability (based on primers/probes sequences) of the NAT system to detect such other species.

Based on the results from this validation of the specificity, if a gap in the specificity of the method is identified (such as detection of non-mycoplasmal bacterial nucleic acid), an appropriate strategy must be proposed in the validation study to allow interpretation of positive results on a routine basis. For example, a second test may be performed using an alternative method without this specificity gap or using an official method.

2-2. **Detection limit**. The detection limit of an individual analytical procedure is the lowest amount of target nucleic acid in a sample that can be detected but not necessarily quantitated as an exact value.

For establishment of the detection limit, a positive cut-off point should be determined for the nucleic acid amplification analytical procedure. The positive cut-off point (as defined in general chapter *2.6.21*) is the minimum number of target sequence copies per volume of sample that can be detected in 95 per cent of test runs. This positive cut-off point is influenced by the distribution of mycoplasmal genomes in the individual samples being tested and by factors such as enzyme efficiency, and can result in different 95 per cent cut-off values for individual analytical test runs.

To determine the positive cut-off point, a dilution series of characterised and calibrated (either in CFUs or nucleic acid copies) in-house working strains or EDQM standards should be tested on different days to examine variation between test runs.

For validation of the limit of detection, the following species represent an optimal selection in terms of the frequency of occurrence as contaminants and phylogenetic relationships:

- *A. laidlawii*;
- *M. fermentans*;
- *M. hyorhinis*;
- *M. pneumoniae* or *M. gallisepticum*;
- *M. synoviae* (where there is use of or exposure to avian material during production);
- *M. arginini*;
- *S. citri* (where there is use of or exposure to insect or plant material during production).

For each strain, at least 3 independent 10-fold dilution series should be tested, with a sufficient number of replicates at each dilution to give a total number of 24 test results for each dilution, to enable a statistical analysis of the results.

For example, a laboratory may test 3 dilution series on different days with 8 replicates for each dilution, 4 dilution series on different days with 6 replicates for each dilution, or 6 dilution series on different days with 4 replicates for each dilution. In order to keep the number of dilutions at a manageable level, a preliminary test should be performed to obtain a preliminary value for the positive cut-off point (i.e. the highest dilution giving a positive signal). The range of dilutions can then be chosen around the predetermined preliminary cut-off point. The concentration of mycoplasmas (CFUs or copies) that can be detected in 95 per cent of test runs can then be calculated using an appropriate statistical evaluation.

These results may also serve to evaluate the variability of the analytical procedure.

2-3. **Robustness**. The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters, and provides an indication of its reliability during normal usage.

The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. However, the robustness of the method can be demonstrated during its development when small variations in the concentrations of reagents (e.g. $MgCl_2$, primers or deoxyribonucleotides) are tested. Modifications of extraction kits or extraction procedures as well as different thermal cycler types may also be evaluated.

Finally, robustness of the method can be evaluated through collaborative studies.

3. *GUIDELINE FOR COMPARABILITY STUDY*

NAT may be used instead of official methods (indicator cell culture method and/or culture method). In this case a comparability study should be carried out. This comparability study should include mainly a comparison of the respective detection limits of the alternative method and official methods. However, specificity (mycoplasma panel detected, putative false positive results) should also be considered.

For the detection limit, acceptability criteria are defined as follows:

– if the alternative method is proposed to replace the culture method, the NAT system must be shown to detect 10 CFU/ml for each mycoplasma test species described in paragraph 2-2;
– if the alternative method is proposed to replace the indicator cell culture method, the NAT system must be shown to detect 100 CFU/ml for each mycoplasma test species described in paragraph 2-2.

For both cases, suitable standards calibrated for the number of nucleic acid copies and the number of CFUs may be used for establishing that these acceptability criteria are reached. The relation between CFUs and nucleic acid copies for the reference preparations should be previously established to compare the performance of the alternative NAT method with the performance of the official methods.

1 of the following 2 strategies can be used to perform this comparability study:

– perform the NAT alternative method in parallel with the official method(s) to evaluate simultaneously the detection limit of both methods using the same samples of calibrated strains;
– compare the performance of the NAT alternative method using previously obtained data from official method validation. In this case, calibration of standards used for both validations as well as their stabilities should be documented carefully.

Comparability study reports should describe all the validation elements described in section 2 (specificity, limit of detection and variability, as well as robustness) in order to assess all the advantages and/or disadvantages of the alternative NAT method compared to official methods.

01/2008:20608

2.6.8. PYROGENS

The test consists of measuring the rise in body temperature evoked in rabbits by the intravenous injection of a sterile solution of the substance to be examined.

Selection of animals. Use healthy, adult rabbits of either sex weighing not less than 1.5 kg, fed a complete and balanced diet not containing antibiotics, and not showing loss of body mass during the week preceding the test. A rabbit is not be used in a pyrogen test:

a) if it has been used in a negative pyrogen test in the preceding 3 days, or

b) if it has been used in the preceding 3 weeks in a pyrogen test in which the substance under examination failed to pass the test.

Animals' quarters. Keep the rabbits individually in a quiet area with a uniform appropriate temperature. Withhold food from the rabbits overnight and until the test is completed; withhold water during the test. Carry out the test in a quiet room where there is no risk of disturbance exciting the animals and in which the room temperature is within 3 °C of that of the rabbits' living quarters, or in which the rabbits have been kept for at least 18 h before the test.

Materials. Glassware, syringes and needles. Thoroughly wash all glassware, syringes and needles with water for injections and heat in a hot-air oven at 250 °C for 30 min or at 200 °C for 1 h.

Retaining boxes. The retaining boxes for rabbits whose temperature is being measured by an electrical device are made in such a way that the animals are retained only by loosely fitting neck-stocks; the rest of the body remains relatively free so that the rabbits may sit in a normal position. They are not restrained by straps or other similar methods which may harm the animal. The animals are put into the boxes not less than 1 h before the first record of the temperature and remain in them throughout the test.

Thermometers. Use a thermometer or electrical device which indicates the temperature with a precision of 0.1 °C and insert into the rectum of the rabbit to a depth of about 5 cm. The depth of insertion is constant for any one rabbit in any one test. When an electrical device is used it may be left in position throughout the test.

Preliminary test. After selection of the animals, one to three days before testing the product to be examined, treat those animals that have not been used during the previous 2 weeks by intravenous injection of 10 ml per kilogram of body mass of a pyrogen-free 9 g/l solution of *sodium chloride R* warmed to about 38.5 °C. Record the temperatures of the animals, beginning at least 90 min before injection and continuing for 3 h after the injection of the solution. Any animal showing a temperature variation greater than 0.6 °C is not used in the main test.

Main test. Carry out the test using a group of three rabbits.

Preparation and injection of the product. Warm the liquid to be examined to approximately 38.5 °C before the injection. The product to be examined may be dissolved in, or diluted with, a pyrogen-free 9 g/l solution of *sodium chloride R* or another prescribed liquid. Inject the solution slowly into the marginal vein of the ear of each rabbit over a period not exceeding 4 min, unless otherwise prescribed in the monograph. The amount of the product to be injected varies according to the product to be examined and is prescribed in the monograph. The volume injected is not less than 0.5 ml per kilogram and not more than 10 ml per kilogram of body mass.

Determination of the initial and maximum temperatures. The "initial temperature" of each rabbit is the mean of two temperature readings recorded for that rabbit at an interval of 30 min in the 40 min immediately preceding the injection of the product to be examined. The "maximum temperature" of each rabbit is the highest temperature recorded for that rabbit in the 3 h after the injection. Record

the temperature of each rabbit at intervals of not more than 30 min, beginning at least 90 min before the injection of the product to be examined and continuing 3 h after the injection. The difference between the maximum temperature and the initial temperature of each rabbit is taken to be its response. When this difference is negative, the result is counted as a zero response.

Rabbits showing a temperature variation greater than 0.2 °C between two successive readings in the determination of the initial temperature are withdrawn from the test. In any one test, only rabbits having initial temperatures which do not differ from one another by more than 1 °C are used. All rabbits having an initial temperature higher than 39.8 °C or less than 38.0 °C are withdrawn from the test.

Interpretation of results. Having carried out the test first on a group of three rabbits, repeat if necessary on further groups of three rabbits to a total of four groups, depending on the results obtained. If the summed response of the first group does not exceed the figure given in the second column of the Table 2.6.8.-1, the substance passes the test. If the summed response exceeds the figure given in the second column of the table but does not exceed the figure given in the third column of the table, repeat the test as indicated above. If the summed response exceeds the figure given in the third column of the table, the product fails the test.

Table 2.6.8.-1

Number of rabbits	Product passes if summed response does not exceed	Product fails if summed response exceeds
3	1.15 °C	2.65 °C
6	2.80 °C	4.30 °C
9	4.45 °C	5.95 °C
12	6.60 °C	6.60 °C

Rabbits used in a test for pyrogens where the mean rise in the rabbits' temperature has exceeded 1.2 °C are permanently excluded.

01/2008:20609

2.6.9. ABNORMAL TOXICITY

GENERAL TEST

Inject intravenously into each of 5 healthy mice, weighing 17 g to 24 g, the quantity of the substance to be examined prescribed in the monograph, dissolved in 0.5 ml of *water for injections R* or of a 9 g/l sterile solution of *sodium chloride R*. Inject the solution over a period of 15 s to 30 s, unless otherwise prescribed.

The substance passes the test if none of the mice die within 24 h or within such time as is specified in the individual monograph. If more than one animal dies the preparation fails the test. If one of the animals dies, repeat the test. The substance passes the test if none of the animals in the 2nd group die within the time interval specified.

IMMUNOSERA AND VACCINES FOR HUMAN USE

Unless otherwise prescribed, inject intraperitoneally 1 human dose but not more than 1.0 ml into each of 5 healthy mice, weighing 17 g to 24 g. The human dose is that stated on the label of the preparation to be examined or on the accompanying leaflet. Observe the animals for 7 days.

The preparation passes the test if none of the animals shows signs of ill health. If more than one animal dies, the preparation fails the test. If one of the animals dies or shows signs of ill health, repeat the test. The preparation passes the test if none of the animals in the 2nd group die or shows signs of ill health in the time interval specified.

The test must also be carried out on 2 healthy guinea-pigs weighing 250 g to 400 g. Inject intraperitoneally into each animal 1 human dose but not more than 5.0 ml. The human dose is that stated on the label of the preparation to be examined or on the accompanying leaflet. Observe the animals for 7 days.

The preparation passes the test if none of the animals shows signs of ill health. If more than one animal dies the preparation fails the test. If one of the animals dies or shows signs of ill health, repeat the test. The preparation passes the test if none of the animals in the 2nd group die or shows signs of ill health in the time interval specified.

01/2008:20610

2.6.10. HISTAMINE

Euthanise a guinea-pig weighing 250 g to 350 g that has been deprived of food for the preceding 24 h. Remove a portion of the distal small intestine 2 cm in length and empty the isolated part by rinsing carefully with solution B described below using a syringe. Attach a fine thread to each end and make a small transverse incision in the middle of the piece of intestine. Place it in an organ bath with a capacity of 10 ml to 20 ml, containing solution B maintained at a constant temperature (34 °C to 36 °C) and pass through the solution a current of a mixture of 95 parts of oxygen and 5 parts of carbon dioxide. Attach one of the threads near to the bottom of the organ bath. Attach the other thread to an isotonic myograph and record the contractions of the organ on a kymograph or other suitable means of giving a permanent record. If a lever is used, its length is such that the movements of the organ are amplified about 20 times. The tension on the intestine should be about 9.8 mN (1 g) and it should be adjusted to the sensitivity of the organ. Flush out the organ bath with solution B. Allow it to stand for 10 min. Flush 2 or 3 times more with solution B. Stimulate a series of contractions by the addition of measured volumes between 0.2 ml and 0.5 ml of a solution of *histamine dihydrochloride R* having a strength which produces reproducible submaximal responses. This dose is termed the "high dose". Flush the organ bath (preferably by overflow without emptying the bath) 3 times with solution B before each addition of histamine. The successive additions should be made at regular intervals allowing a complete relaxation between additions (about 2 min). Add equal volumes of a weaker dilution of *histamine dihydrochloride R* which produces reproducible responses approximately half as great as the "high dose". This dose is termed the "low dose". Continue the regular additions of "high" and "low" doses of histamine solution as indicated above, and alternate each addition with an equal volume of a dilution of the solution to be examined, adjusting the dilution so that the contraction of the intestine, if any, is smaller than that due to the "high dose" of histamine. Determine whether the contraction, if any, is reproducible and that the responses to the "high" and "low" doses of histamine are unchanged. Calculate the activity of the substance to be examined in terms of its equivalent in micrograms of histamine base from the dilution determined as above.

The quantity so determined does not exceed the quantity prescribed in the monograph.

If the solution to be examined does not produce a contraction, prepare a fresh solution adding a quantity of histamine corresponding to the maximum tolerated in the

monograph and note whether the contractions produced by the preparation with the added histamine correspond to the amount of histamine added. If this is not the case, or if the contractions caused by the substance to be examined are not reproducible or if subsequent responses to "high" and "low" doses of histamine are diminished, the results of the tests are invalid and the test for depressor substances (*2.6.11*) must be carried out.

Solution A

Sodium chloride	160.0 g
Potassium chloride	4.0 g
Calcium chloride, anhydrous	2.0 g
Magnesium chloride, anhydrous	1.0 g
Disodium hydrogen phosphate dodecahydrate	0.10 g
Water for injections R sufficient to produce	1000 ml

Solution B

Solution A	50.0 ml
Atropine sulphate	0.5 mg
Sodium hydrogen carbonate	1.0 g
Glucose monohydrate	0.5 g
Water for injections R sufficient to produce	1000 ml

Solution B should be freshly prepared and used within 24 h.

01/2008:20611

2.6.11. DEPRESSOR SUBSTANCES

Carry out the test on a cat weighing not less than 2 kg and anaesthetised with chloralose or with a barbiturate that allows the maintenance of uniform blood pressure. Protect the animal from loss of body heat and maintain it so that the rectal temperature remains within physiological limits. Introduce a cannula into the trachea. Insert a cannula filled with a heparinised 9 g/l solution of sodium chloride into the common carotid artery and connect it to a device capable of giving a continuous record of the blood pressure. Insert into the femoral vein another cannula, filled with a heparinised 9 g/l solution of sodium chloride, through which can be injected the solutions of histamine and of the substance to be examined. Determine the sensitivity of the animal to histamine by injecting intravenously at regular intervals, doses of *histamine solution R* corresponding to 0.1 µg and 0.15 µg of histamine base per kilogram of body mass. Repeat the lower dose at least 3 times. Administer the second and subsequent injections not less than 1 min after the blood pressure has returned to the level it was at immediately before the previous injection. The animal is used for the test only if a readily discernible decrease in blood pressure that is constant for the lower dose is obtained and if the higher dose causes greater responses. Dissolve the substance to be examined in sufficient of a 9 g/l solution of sodium chloride or other prescribed solvent, to give the prescribed concentration. Inject intravenously per kilogram of body mass 1.0 ml of *histamine solution R*, followed by 2 successive injections of the prescribed amount of the solution to be examined and, finally, 1.0 ml of *histamine solution R*. The second, third and fourth injections are given not less than 1 min after the blood pressure has returned to the level it was at immediately before the preceding injection. Repeat this series of injections twice and conclude the test by giving 1.5 ml of *histamine solution R* per kilogram of body mass.

If the response to 1.5 ml of *histamine solution R* per kilogram of body mass is not greater than that to 1.0 ml the test is invalid. The substance to be examined fails the test if the mean of the series of responses to the substance is greater than the mean of the responses to 1.0 ml of *histamine solution R* per kilogram of body mass or if any one dose of the substance causes a greater depressor response than the concluding dose of the histamine solution. The test animal must not be used in another test for depressor substances if the second criterion applies or if the response to the high dose of histamine given after the administration of the substance to be examined is less than the mean response to the low doses of histamine previously injected.

01/2008:20612

2.6.12. MICROBIOLOGICAL EXAMINATION OF NON-STERILE PRODUCTS: TOTAL VIABLE AEROBIC COUNT

This general chapter presents 2 sets of tests. The 1st set gives the reference methods for determining compliance with monographs. Reference to this chapter in a monograph therefore implies compliance with the 1st set of tests, unless use of the 2nd set of tests has been authorised. The tests in the 2nd set also constitute official methods of the European Pharmacopoeia and may be referred to as such, notably in applications for marketing authorisation. It is intended to replace the 1st set by the 2nd set once the monographs concerned have been revised. The 2nd set presents tests developed in co-operation with the Japanese Pharmacopoeia and the United States Pharmacopeia to achieve harmonised requirements.

A. METHOD OF THE EUROPEAN PHARMACOPOEIA

The tests described hereafter will allow quantitative enumeration of mesophilic bacteria and fungi that may grow under aerobic conditions.

The tests are designed primarily to determine whether or not a substance that is the subject of a monograph in the Pharmacopoeia complies with the microbiological requirements specified in the monograph in question. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below. The tests may also be used for the test for *Efficacy of antimicrobial preservation* (*5.1.3*) as described in the Pharmacopoeia. They may furthermore be used for monitoring raw material quality and may be used in association with guidelines on microbiological quality (*5.1.4*). When used for such purposes, for example by a manufacturer for raw materials and/or finished product monitoring or for process validation, the conduct of the tests including the number of samples to be taken and the interpretation of the results are matters for agreement between the manufacturer and the competent authority.

Carry out the determination under conditions designed to avoid accidental contamination of the product to be examined. The precautions taken to avoid contamination must be such that they do not affect any micro-organisms that are revealed in the test. If the product to be examined has antimicrobial activity, this must be adequately neutralised. If inactivators are used for this purpose, their efficacy and non-toxicity versus micro-organisms are demonstrated.

Determine the total viable aerobic count by the membrane filtration method or the plate-count method, as prescribed in the monograph.

The Most Probable Number (MPN) method is reserved for bacterial counts when no other method is available. The choice of a method may be based on factors such as the nature of the product and the expected number of micro-organisms. Any method that is chosen must be properly validated.

When used in conjunction with chapter *5.1.3* or *5.1.4*, the pour-plate method, the surface-spread method and the membrane filtration method may be used.

PREPARATION OF THE SAMPLE

Sampling plan. Sampling of the product must follow a well-defined sampling plan. The sampling plan will be dependent on factors such as batch size, health hazard associated with unacceptably highly contaminated products, the characteristics of the product and the expected level of contamination. Unless otherwise prescribed, use sample(s) of 10 g or 10 ml of the substance or preparation to be examined, taken with the precautions referred to above. Select the sample(s) at random from the bulk material or from the available containers of the preparation. If necessary, to obtain the required quantity, mix the contents of a sufficient number of containers to provide each sample, depending on the nature of the substance or preparation to be examined.

An example of a sampling plan applicable to products where homogeneity with respect to the distribution of micro-organisms may be a problem, is the three-class sampling plan. In this case five samples from each batch are drawn and investigated separately. The three recognised classes are:

(i) acceptable samples, i.e. samples containing less than m CFU (colony-forming units) per gram or millilitre, where m is the limit specified in the relevant monograph;

(ii) marginal samples, i.e. with more than m CFU but less than $10m$ CFU per gram or millilitre;

(iii) defective samples, i.e. containing more than $10m$ CFU per gram or millilitre.

Water-soluble products. Dissolve or dilute 10 g or 10 ml of the product to be examined in buffered sodium chloride-peptone solution pH 7.0 or in another suitable liquid. In general a one in ten dilution is prepared. However, the characteristics of the product or the required sensitivity may necessitate the use of other ratios. If the product is known to have antimicrobial activity, an inactivating agent may be added to the diluent. If necessary, adjust the pH to about pH 7 and prepare further serial tenfold dilutions using the same diluent.

Non-fatty products insoluble in water. Suspend 10 g or 10 ml of the product to be examined in buffered sodium chloride-peptone solution pH 7.0 or in another suitable liquid. In general a one in ten suspension is prepared, but the characteristics of some products may necessitate the use of larger volumes. A suitable surface-active agent such as 1 g/l of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If the product is known to have antimicrobial activity, an inactivating agent may be added to the diluent. If necessary, adjust to about pH 7 and prepare further serial tenfold dilutions using the same diluent.

Fatty products. Homogenise 10 g or 10 ml of the product to be examined with not more than half its weight of sterile polysorbate 80 or another suitable sterile surface-active agent, heated if necessary to not more than 40 °C, or in exceptional cases to not more than 45 °C. Mix carefully and if necessary maintain the temperature in a water-bath or in an incubator. Add sufficient pre-warmed buffered sodium chloride-peptone solution pH 7.0 to make a one in ten dilution of the original product. Mix carefully whilst maintaining the temperature for the shortest time necessary for the formation of an emulsion and in any case for not more than 30 min. Further serial tenfold dilutions may be prepared using buffered sodium chloride-peptone solution pH 7.0 containing a suitable concentration of sterile polysorbate 80 or another sterile surface-active agent.

Transdermal patches. Remove the protective cover sheets ('release liners') of ten patches of the transdermal preparation using sterile forceps, and place them, the adhesive side upwards, on sterile glass or plastic trays. Cover the adhesive surface with sterile gauze (or a woven-filter type monofilament polymer grid), if necessary, and transfer the ten patches to a minimum volume of 500 ml of buffered sodium chloride-peptone solution pH 7.0 containing suitable inactivators such as polysorbate 80 and/or lecithin. Shake the preparation vigorously for at least 30 min (preparation A). Prepare another ten patches in the same way, place them in a minimum volume of 500 ml of broth medium D and shake vigorously for at least 30 min (preparation B).

EXAMINATION OF THE SAMPLE

Membrane filtration. Use membrane filters having a nominal pore size not greater than 0.45 µm and whose effectiveness to retain bacteria has been established. The type of filter material is chosen such that the bacteria-retaining efficiency is not affected by the components of the sample to be investigated. Cellulose nitrate filters, for example, may be used for aqueous, oily and weakly alcoholic solutions, and cellulose acetate filters, for example, for strongly alcoholic solutions. The filtration apparatus is designed to allow the transfer of the filter to the culture medium.

Transfer a suitable amount of the sample prepared as described in the section Preparation of the sample (preferably representing 1 g of the product, or less if large numbers of colony-forming units are expected) to each of 2 membrane filters and filter immediately. Wash each filter with 3 quantities, each of about 100 ml of a suitable liquid such as buffered sodium chloride-peptone solution pH 7.0. To this solution, surface-active agents such as polysorbate 80, or inactivators of antimicrobial agents may be added. If validated, less than 3 washes may be applied. Transfer one of the membrane filters, intended primarily for the enumeration of bacteria, to the surface of a suitable agar medium, such as medium B and the other, intended primarily for the enumeration of fungi, to the surface of a suitable agar medium, such as medium C. Incubate the plate of agar medium B at 30-35 °C, and the plate of agar medium C at 20-25 °C, for 5 days, unless a reliable count is obtained in a shorter time. Select plates with the highest number below 100 colonies and calculate the number of colony-forming units per gram or millilitre of product.

When examining transdermal patches, filter 50 ml of preparation A separately through each of 2 sterile filter membranes. Transfer one membrane to agar medium B for total aerobic microbial count, and the other membrane to agar medium C for the count of fungi.

Plate-count methods

a. Pour-plate method. Using Petri dishes 9 cm in diameter, add to each dish 1 ml of the sample prepared as described in the section Preparation of the sample and 15-20 ml of a liquefied agar medium suitable for the cultivation of bacteria (such as medium B), or 15-20 ml of a liquefied agar medium suitable for the cultivation of fungi (such as medium C) at not more than 45 °C. If larger Petri dishes are used the amount of agar is increased accordingly. Prepare for each medium at least 2 Petri dishes for each level of dilution. Incubate the plates at 30-35 °C (20-25 °C for fungi) for 5 days, unless a reliable count is obtained in a shorter time.

Select the plates corresponding to 1 dilution and showing the highest number of colonies less than 300 (100 for fungi). Take the arithmetic average of the counts and calculate the number of colony-forming units per gram or millilitre.

b. Surface-spread method. Using Petri dishes 9 cm in diameter, add 15-20 ml of a liquefied agar medium suitable for the cultivation of bacteria (such as medium B) or a liquefied agar medium suitable for the cultivation of fungi (such as medium C) at about 45 °C to each Petri dish and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example in a laminar-air-flow cabinet or an incubator. Spread a measured volume of not less than 0.1 ml of the sample prepared as described in the section Preparation of the sample over the surface of the medium. Use at least 2 Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of colony-forming units proceed as described for the pour-plate method.

Most-probable-number method

Table 2.6.12.-1. – *Most-probable-number values of bacteria*

3 tubes at each level of dilution							
Number of positive tubes			MPN per gram	Category*		95 per cent confidence limits	
0.1 g	0.01 g	0.001 g		1	2		
0	0	0	< 3			–	–
0	1	0	3		x	< 1	17
1	0	0	3	x		1	21
1	0	1	7		x	2	27
1	1	0	7	x		2	28
1	2	0	11		x	4	35
2	0	0	9	x		2	38
2	0	1	14		x	5	48
2	1	0	15	x		5	50
2	1	1	20		x	8	61
2	2	0	21	x		8	63
3	0	0	23	x		7	129
3	0	1	38	x		10	180
3	1	0	43	x		20	210
3	1	1	75	x		20	280
3	2	0	93	x		30	390
3	2	1	150	x		50	510
3	2	2	210		x	80	640
3	3	0	240	x		100	1400
3	3	1	460	x		200	2400
3	3	2	1100	x		300	4800
3	3	3	> 1100			–	–

* Category 1: Normal results, obtained in 95 per cent of the cases.

* Category 2: Less likely results, obtained in only 4 per cent of cases. These are not to be used for important decisions. Results that are even less likely than those of category 2 are not mentioned and are always unacceptable.

The precision and accuracy of the most-probable-number method (MPN) is less than that of the membrane filtration method or the plate-count methods. Unreliable results are obtained particularly for the enumeration of moulds. For these reasons the MPN method is reserved for the enumeration of bacteria in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least 3 subsequent tenfold dilutions of the product as described in the section Preparation of the sample. From each level of dilution, 3 aliquots of 1 g or 1 ml are used to inoculate 3 tubes with 9-10 ml of a suitable liquid medium (such as broth medium A). If necessary, a surface-active agent such as polysorbate 80 or an inactivator of antimicrobial agents may be added to the medium. Thus, if 3 levels of dilution are prepared, 9 tubes are inoculated. Incubate all tubes for 5 days at 30-35 °C. Record for each level of dilution the number of tubes showing microbial growth. If the reading of the results is difficult or uncertain owing to the nature of the product to be examined, subculture in the same broth, or on a suitable agar medium (such as agar medium B), for 18-24 h at the same temperature and use these results. Determine the most probable number of bacteria per gram or millilitre of the product to be examined from Table 2.6.12.-1.

EFFECTIVENESS OF CULTURE MEDIA AND VALIDITY OF THE COUNTING METHOD

Grow the bacterial test strains separately in containers containing a suitable liquid medium (such as broth medium A) at 30-35 °C for 18-24 h. Grow the fungal test strains separately on a suitable agar medium (such as medium C without antibiotics) at 20-25 °C for 48 h for *Candida albicans* and at 20-25 °C for 7 days for *Aspergillus niger*.

Staphylococcus aureus	such as ATCC 6538 (NCIMB 9518, CIP 4.83)
Escherichia coli	such as ATCC 8739 (NCIMB 8545, CIP 53.126)
Bacillus subtilis	such as ATCC 6633 (NCIMB 8054, CIP 52.62)
Candida albicans	such as ATCC 10231 (NCPF 3179, IP 48.72)
Aspergillus niger	such as ATCC 16404 (IMI 149007, IP 1431.83)

Use buffered sodium chloride-peptone solution pH 7.0 to make reference suspensions containing about 100 colony-forming units per millilitre. Use the suspension of each of the micro-organisms separately as a control of the counting methods, in the presence and absence of the product to be examined. When testing the membrane filtration method or the plate-count method, a count of any of the test organisms differing by not more than a factor of 5 from the calculated value from the inoculum is to be obtained. When testing the most-probable-number method the calculated value from the inoculum is to be within the 95 per cent confidence limits of the results obtained. To test the sterility of the medium and of the diluent and the aseptic performance of the test, carry out the method using sterile sodium chloride-peptone solution pH 7.0 as the test preparation. There must be no growth of micro-organisms.

INTERPRETATION OF THE RESULTS

The bacterial count will be considered to be equal to the average number of colony-forming units found on agar medium B. The fungal count will be considered to be equal to the average number of colony-forming units on agar medium C. The total viable aerobic count is the sum of the bacterial count and the fungal count as described above. If there is evidence that the same types of micro-organisms grow on both media this may be corrected. If the count is carried out by the most-probable-number method the calculated value is the bacterial count.

When a limit is prescribed in a monograph it is interpreted as follows:

10^2 micro-organisms: maximum acceptable limit: 5×10^2;

10^3 micro-organisms: maximum acceptable limit: 5×10^3; and so forth.

If a sampling plan such as the three-class sampling plan, for example, is used, proceed as follows.

Calculate the total viable aerobic count separately for each of the five samples. The substance or preparation passes the test if the following conditions are fulfilled:

(i) none of the individual total viable aerobic counts exceeds the prescribed limit by a factor of 10 or more (i.e. no 'unacceptable samples');

(ii) not more than 2 of the individual total viable aerobic counts are between the prescribed limit and 10 times this limit (i.e. no more than 2 'marginal samples').

The solutions and culture mediums recommended are described in the general chapter *2.6.13*.

B. HARMONISED METHOD: MICROBIOLOGICAL EXAMINATION OF NON-STERILE PRODUCTS: MICROBIAL ENUMERATION TESTS

1. INTRODUCTION

The tests described hereafter will allow quantitative enumeration of mesophilic bacteria and fungi that may grow under aerobic conditions.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

The methods are not applicable to products containing viable micro-organisms as active ingredients.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2. GENERAL PROCEDURES

Carry out the determination under conditions designed to avoid extrinsic microbial contamination of the product to be examined. The precautions taken to avoid contamination must be such that they do not affect any micro-organisms that are to be revealed in the test.

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralised. If inactivators are used for this purpose, their efficacy and their absence of toxicity for micro-organisms must be demonstrated.

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated.

3. ENUMERATION METHODS

Use the membrane filtration method or the plate-count methods, as prescribed. The most-probable-number (MPN) method is generally the least accurate method for microbial counts, however, for certain product groups with a very low bioburden, it may be the most appropriate method.

The choice of method is based on factors such as the nature of the product and the required limit of micro-organisms. The chosen method must allow testing of a sufficient sample size to judge compliance with the specification. The suitability of the method chosen must be established.

4. GROWTH PROMOTION TEST AND SUITABILITY OF THE COUNTING METHOD

4-1. *GENERAL CONSIDERATIONS*

The ability of the test to detect micro-organisms in the presence of product to be tested must be established.

Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

4-2. *PREPARATION OF TEST STRAINS*

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot. Grow each of the bacterial and fungal test strains separately as described in Table 2.6.12.-2.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions; to suspend *A. niger* spores, 0.05 per cent of polysorbate 80 may be added to the buffer. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *A. niger* or *B. subtilis*, a stable spore suspension is prepared and then an appropriate volume of the spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period of time.

4-3. *NEGATIVE CONTROL*

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms.

4-4. *GROWTH PROMOTION OF THE MEDIA*

Test each batch of ready-prepared medium and each batch of medium, prepared either from dehydrated medium or from the ingredients described.

Inoculate portions/plates of casein soya bean digest broth and casein soya bean digest agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.12.-2, using a separate portion/plate of medium for each. Inoculate plates of Sabouraud-dextrose agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.12.-2, using a separate plate of medium for each. Incubate in the conditions described in Table 2.6.12.-2.

For solid media, growth obtained must not differ by a factor greater than 2 from the calculated value for a standardised inoculum. For a freshly prepared inoculum, growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs. Liquid media are suitable if clearly visible growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

4-5. *SUITABILITY OF THE COUNTING METHOD IN THE PRESENCE OF PRODUCT*

4-5-1. **Preparation of the sample**. The method for sample preparation depends upon the physical characteristics of the product to be tested. If none of the procedures described below can be demonstrated to be satisfactory, an alternative procedure must be developed.

Water-soluble products. Dissolve or dilute (usually a 1 in 10 dilution is prepared) the product to be examined in buffered sodium chloride-peptone solution pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.

Table 2.6.12.-2. – *Preparation and use of test micro-organisms*

Micro-organism	Preparation of test strain	Growth promotion		Suitability of counting method in the presence of the product	
		Total aerobic microbial count	Total yeasts and moulds count	Total aerobic microbial count	Total yeasts and moulds count
Staphylococcus aureus such as: ATCC 6538 NCIMB 9518 CIP 4.83 NBRC 13276	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Pseudomonas aeruginosa such as: ATCC 9027 NCIMB 8626 CIP 82.118 NBRC 13275	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Bacillus subtilis such as: ATCC 6633 NCIMB 8054 CIP 52.62 NBRC 3134	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Candida albicans such as: ATCC 10231 NCPF 3179 IP 48.72 NBRC 1594	Sabouraud-dextrose agar or Sabouraud-dextrose broth 20-25 °C 2-3 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days	Sabouraud-dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days MPN: not applicable	Sabouraud-dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days
Aspergillus niger such as: ATCC 16404 IMI 149007 IP 1431.83 NBRC 9455	Sabouraud-dextrose agar or potato-dextrose agar 20-25 °C 5-7 days, or until good sporulation is achieved	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days	Sabouraud-dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days MPN: not applicable	Sabouraud-dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days

Non-fatty products insoluble in water. Suspend the product to be examined (usually a 1 in 10 dilution is prepared) in buffered sodium chloride-peptone solution pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. A surface-active agent such as 1 g/l of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.

Fatty products. Dissolve in isopropyl myristate, sterilised by filtration or mix the product to be examined with the minimum necessary quantity of sterile polysorbate 80 or another non-inhibitory sterile surface-active agent, heated if necessary to not more than 40 °C, or in exceptional cases to not more than 45 °C. Mix carefully and if necessary maintain the temperature in a water-bath. Add sufficient of the pre-warmed chosen diluent to make a 1 in 10 dilution of the original product. Mix carefully whilst maintaining the temperature for the shortest time necessary for the formation of an emulsion. Further serial tenfold dilutions may be prepared using the chosen diluent containing a suitable concentration of sterile polysorbate 80 or another non-inhibitory sterile surface-active agent.

Fluids or solids in aerosol form. Aseptically transfer the product into a membrane filter apparatus or a sterile container for further sampling. Use either the total contents or a defined number of metered doses from each of the containers tested.

Transdermal patches. Remove the protective cover sheets ('release liners') of the transdermal patches and place them, adhesive side upwards, on sterile glass or plastic trays. Cover the adhesive surface with a sterile porous material, for example sterile gauze, to prevent the patches from sticking together, and transfer the patches to a suitable volume of the chosen diluent containing inactivators such as polysorbate 80 and/or lecithin. Shake the preparation vigorously for at least 30 min.

4-5-2. **Inoculation and dilution.** Add to the sample prepared as described above (4-5-1) and to a control (with no test material included) a sufficient volume of the microbial suspension to obtain an inoculum of not more than 100 CFU. The volume of the suspension of the inoculum should not exceed 1 per cent of the volume of diluted product.

To demonstrate acceptable microbial recovery from the product, the lowest possible dilution factor of the prepared sample must be used for the test. Where this is not possible due to antimicrobial activity or poor solubility, further appropriate protocols must be developed. If inhibition of growth by the sample cannot otherwise be avoided, the aliquot of the microbial suspension may be added after neutralisation, dilution or filtration.

4-5-3. **Neutralisation/removal of antimicrobial activity.** The number of micro-organisms recovered from the prepared sample diluted as described in 4-5-2 and incubated following the procedure described in 4-5-4, is compared to the number of micro-organisms recovered from the control preparation.

If growth is inhibited (reduction by a factor greater than 2), then modify the procedure for the particular enumeration test to ensure the validity of the results. Modification of the procedure may include, for example, (1) an increase in the

volume of the diluent or culture medium, (2) incorporation of specific or general neutralising agents into the diluent, (3) membrane filtration, or (4) a combination of the above measures.

Neutralising agents. Neutralising agents may be used to neutralise the activity of antimicrobial agents (Table 2.6.12.-3). They may be added to the chosen diluent or the medium preferably before sterilisation. If used, their efficacy and their absence of toxicity for micro-organisms must be demonstrated by carrying out a blank with neutraliser and without product.

Table 2.6.12.-3. – *Common neutralising agents for interfering substances*

Interfering substance	Potential neutralising method
Glutaraldehyde, mercurials	Sodium hydrogensulphite (sodium bisulphite)
Phenolics, alcohol, aldehydes, sorbate	Dilution
Aldehydes	Glycine
Quaternary Ammonium Compounds (QACs), parahydroxybenzoates (parabens), bis-biguanides	Lecithin
QACs, iodine, parabens	Polysorbate
Mercurials	Thioglycollate
Mercurials, halogens, aldehydes	Thiosulphate
EDTA (edetate)	Mg^{2+} or Ca^{2+} ions

If no suitable neutralising method can be found, it can be assumed that the failure to isolate the inoculated organism is attributable to the microbicidal activity of the product. This information serves to indicate that the product is not likely to be contaminated with the given species of the micro-organism. However, it is possible that the product only inhibits some of the micro-organisms specified herein, but does not inhibit others not included amongst the test strains or for which the latter are not representative. Then, perform the test with the highest dilution factor compatible with microbial growth and the specific acceptance criterion.

4-5-4. **Recovery of micro-organism in the presence of product**. For each of the micro-organisms listed, separate tests are performed. Only micro-organisms of the added test strain are counted.

4-5-4-1. *Membrane filtration.* Use membrane filters having a nominal pore size not greater than 0.45 µm. The type of filter material is chosen such that the bacteria-retaining efficiency is not affected by the components of the sample to be investigated. For each of the micro-organisms listed, one membrane filter is used.

Transfer a suitable amount of the sample prepared as described under 4-5-1 to 4-5-3 (preferably representing 1 g of the product, or less if large numbers of CFU are expected) to the membrane filter, filter immediately and rinse the membrane filter with an appropriate volume of diluent.

For the determination of total aerobic microbial count (TAMC), transfer the membrane filter to the surface of casein soya bean digest agar. For the determination of total combined yeasts/moulds count (TYMC), transfer the membrane to the surface of Sabouraud-dextrose agar. Incubate the plates as indicated in Table 2.6.12.-2. Perform the counting.

4-5-4-2. *Plate-count methods.* Perform plate-count methods at least in duplicate for each medium and use the mean count of the result.

4-5-4-2-1. Pour-plate method.

For Petri dishes 9 cm in diameter, add to the dish 1 ml of the sample prepared as described under 4-5-1 to 4-5-3 and 15-20 ml of casein soya bean digest agar or Sabouraud-dextrose agar, both media being at not more than 45 °C. If larger Petri dishes are used, the amount of agar medium is increased accordingly. For each of the micro-organisms listed in Table 2.6.12.-2, at least 2 Petri dishes are used. Incubate the plates as indicated in Table 2.6.12.-2. Take the arithmetic mean of the counts per medium and calculate the number of CFU in the original inoculum.

4-5-4-2-2. Surface-spread method.

For Petri dishes 9 cm in diameter, add 15-20 ml of casein soya bean digest agar or Sabouraud-dextrose agar at about 45 °C to each Petri dish and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example in a laminar-air-flow cabinet or an incubator. For each of the micro-organisms listed in Table 2.6.12.-2, at least 2 Petri dishes are used. Spread a measured volume of not less than 0.1 ml of the sample prepared as described under 4-5-1 to 4-5-3 over the surface of the medium. Incubate and count as prescribed under 4-5-4-2-1.

4-5-4-3. *Most-probable-number (MPN) method.* The precision and accuracy of the MPN method is less than that of the membrane filtration method or the plate-count method. Unreliable results are obtained particularly for the enumeration of moulds. For these reasons the MPN method is reserved for the enumeration of TAMC in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least 3 serial tenfold dilutions of the product as described under 4-5-1 to 4-5-3. From each level of dilution, 3 aliquots of 1 g or 1 ml are used to inoculate 3 tubes with 9-10 ml of casein soya bean digest broth. If necessary, a surface-active agent such as polysorbate 80 or an inactivator of antimicrobial agents may be added to the medium. Thus, if 3 levels of dilution are prepared, 9 tubes are inoculated.

Incubate all tubes at 30-35 °C for not more than 3 days. If reading of the results is difficult or uncertain owing to the nature of the product to be examined, subculture in the same broth, or in casein soya bean digest agar, for 1-2 days at the same temperature and use these results. Determine the most probable number of micro-organisms per gram or millilitre of the product to be examined from Table 2.6.12.-4.

4-6. *RESULTS AND INTERPRETATION*

When verifying the suitability of the membrane filtration method or the plate-count method, a mean count of any of the test organisms not differing by a factor greater than 2 from the value of the control defined in 4-5-2 in the absence of the product must be obtained. When verifying the suitability of the MPN method the calculated value from the inoculum must be within 95 per cent confidence limits of the results obtained with the control.

If the above criteria cannot be met for one or more of the organisms tested with any of the described methods, the method and test conditions that come closest to the criteria are used to test the product.

5. TESTING OF PRODUCTS

5-1. *AMOUNT USED FOR THE TEST*

Unless otherwise prescribed, use 10 g or 10 ml of the product to be examined taken with the precautions referred to above. For fluids or solids in aerosol form, sample 10 containers. For transdermal patches, sample 10 patches.

The amount to be tested may be reduced for active substances that will be formulated in the following conditions: the amount per dosage unit (e.g. tablet, capsule, injection) is less than or equal to 1 mg or the amount per gram or millilitre (for preparations not presented in dose units) is less than 1 mg. In these cases, the amount to be tested is not less than the amount present in 10 dosage units or 10 g or 10 ml of the product.

For materials used as active substances where sample quantity is limited or batch size is extremely small (i.e. less than 1000 ml or 1000 g), the amount tested shall be 1 per cent of the batch unless a lesser amount is prescribed or justified and authorised.

For products where the total number of entities in a batch is less than 200 (e.g. samples used in clinical trials), the sample size may be reduced to 2 units, or 1 unit if the size is less than 100.

Select the sample(s) at random from the bulk material or from the available containers of the preparation. To obtain the required quantity, mix the contents of a sufficient number of containers to provide the sample.

5-2. *EXAMINATION OF THE PRODUCT*

5-2-1. **Membrane filtration**

Use a filtration apparatus designed to allow the transfer of the filter to the medium. Prepare the sample using a method that has been shown suitable as described in section 4 and transfer the appropriate amount to each of 2 membrane filters and filter immediately. Wash each filter following the procedure shown to be suitable.

For the determination of TAMC, transfer one of the membrane filters to the surface of casein soya bean digest agar. For the determination of TYMC, transfer the other membrane to the surface of Sabouraud-dextrose agar. Incubate the plate of casein soya bean digest agar at 30-35 °C for 3-5 days and the plate of Sabouraud-dextrose agar at 20-25 °C for 5-7 days. Calculate the number of CFU per gram or per millilitre of product.

When examining transdermal patches, filter 10 per cent of the volume of the preparation described under 4-5-1 separately through each of 2 sterile filter membranes. Transfer one membrane to casein soya bean digest agar for TAMC and the other membrane to Sabouraud-dextrose agar for TYMC.

5-2-2. **Plate-count methods**

5-2-2-1. Pour-plate method.

Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare for each medium at least 2 Petri dishes for each level of dilution. Incubate the plates of casein soya bean digest agar at 30-35 °C for 3-5 days and the plates of Sabouraud-dextrose agar at 20-25 °C for 5-7 days. Select the plates corresponding to a given dilution and showing the highest number of colonies less than 250 for TAMC and 50 for TYMC. Take the arithmetic mean per culture medium of the counts and calculate the number of CFU per gram or per millilitre of product.

Table 2.6.12.-4. – *Most-probable-number values of micro-organisms*

Observed combinations of numbers of tubes showing growth in each set			MPN per grams or per millilitre of product	95 per cent confidence limits

3	3	1	460	90-1980
3	3	2	1100	200-4000
3	3	3	> 1100	

5-2-2-2. Surface-spread method.

Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare at least 2 Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of CFU proceed as described for the pour-plate method.

5-2-3. **Most-probable-number method**

Prepare and dilute the sample using a method that has been shown to be suitable as described in section 4. Incubate all tubes at 30-35 °C for 3-5 days. Subculture if necessary, using the procedure shown to be suitable. Record for each level of dilution the number of tubes showing microbial growth. Determine the most probable number of micro-organisms per gram or millilitre of the product to be examined from Table 2.6.12.-4.

5-3. *INTERPRETATION OF THE RESULTS*

The total aerobic microbial count (TAMC) is considered to be equal to the number of CFU found using casein soya bean digest agar; if colonies of fungi are detected on this medium, they are counted as part of the TAMC. The total combined yeasts/mould count (TYMC) is considered to be equal to the number of CFU found using Sabouraud-dextrose agar; if colonies of bacteria are detected on this medium, they are counted as part of the TYMC. When the TYMC is expected to exceed the acceptance criterion due to the bacterial growth, Sabouraud-dextrose agar containing antibiotics may be used. If the count is carried out by the MPN method the calculated value is the TAMC.

When an acceptance criterion for microbiological quality is prescribed it is interpreted as follows:

– 10^1 CFU: maximum acceptable count = 20;
– 10^2 CFU: maximum acceptable count = 200;
– 10^3 CFU: maximum acceptable count = 2000, and so forth.

The recommended solutions and media are described in general chapter *2.6.13* (under section B, Harmonised method).

01/2008:20613 corrected 6.0

2.6.13. MICROBIOLOGICAL EXAMINATION OF NON-STERILE PRODUCTS: TEST FOR SPECIFIED MICRO-ORGANISMS

This general chapter presents 2 sets of tests. The 1st set gives the reference methods for determining compliance with monographs. Reference to this chapter in a monograph therefore implies compliance with the 1st set of tests, unless use of the 2nd set of tests has been authorised. The tests in the 2nd set also constitute official methods of the European Pharmacopoeia and may be referred to as such, notably in applications for marketing authorisation. It is intended to replace the 1st set by the 2nd set once the monographs concerned have been revised. The 2nd set presents tests developed in co-operation with the Japanese Pharmacopoeia and the United States Pharmacopeia to achieve harmonised requirements.

A. METHOD OF THE EUROPEAN PHARMACOPOEIA

In this general method the use of certain selective media is proposed. A feature common to all selective media is that sub-lethally injured organisms are not detected. As sub-lethally injured organisms are relevant for the quality of the product, a resuscitation must be included in examination procedures that rely on selective media.

If the product to be examined has antimicrobial activity, this must be adequately neutralised.

Enterobacteria and certain other gram-negative bacteria

Although the test has been designed to detect bacteria belonging to the family of Enterobacteriaceae, it is recognised that other types of organisms (e.g. *Aeromonas, Pseudomonas*) may be recovered.

Detection of bacteria. Prepare the product to be examined as described in the general method *2.6.12*, but using broth medium D in place of buffered sodium chloride-peptone solution pH 7.0, homogenise and incubate at 35-37 °C for a time sufficient to revive the bacteria but not sufficient to encourage multiplication of the organisms (usually 2 h but not more than 5 h). Shake the container, transfer the quantity of the contents (homogenate A) corresponding to 1 g or 1 ml of the product to 100 ml of enrichment medium E and incubate at 35-37 °C for 18-48 h. Subculture on plates of agar medium F. Incubate at 35-37 °C for 18-24 h. The product passes the test if there is no growth of colonies of gram-negative bacteria on any plate.

Quantitative evaluation. Inoculate suitable quantities of enrichment broth medium E with homogenate A and/or dilutions of it containing respectively 0.1 g, 0.01 g and 0.001 g (or 0.1 ml, 0.01 ml and 0.001 ml) of the product to be examined. Incubate at 35-37 °C for 24-48 h. Subculture each of the cultures on a plate of agar medium F to obtain selective isolation. Incubate at 35-37 °C for 18-24 h. Growth of well-developed colonies, generally red or reddish, of gram-negative bacteria constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result. Determine from Table 2.6.13.-1 the probable number of bacteria.

Table 2.6.13.-1

Results for each quantity of product			Probable number of bacteria per gram of product
0.1 g or 0.1 ml	0.01 g or 0.01 ml	0.001 g or 0.001 ml	
+	+	+	More than 10^3
+	+	–	Less than 10^3 and more than 10^2
+	–	–	Less than 10^2 and more than 10
–	–	–	Less than 10

When testing transdermal patches, filter 50 ml of preparation B as described in the general method *2.6.12* through a sterile filter membrane, place the membrane in 100 ml of enrichment broth medium E and incubate at 35-37 °C for 18-24 h. After incubation, spread on agar medium F for the detection of Enterobacteria and other gram-negative micro-organisms.

Escherichia coli

Prepare the product to be examined as described in the general method *2.6.12* and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate 100 ml of broth medium A, homogenise and incubate at 35-37 °C for 18-48 h. Shake the container, transfer 1 ml to 100 ml of broth medium G and incubate at 43-45 °C for 18-24 h. Subculture on plates of agar medium H at 35-37 °C for 18-72 h. Growth of red, non-mucoid colonies of gram-negative rods indicates the possible presence of *E. coli*. This is confirmed by suitable biochemical tests, such as indole production. The

product passes the test if such colonies are not seen or if the confirmatory biochemical tests are negative.

Salmonella

Prepare the product to be examined as described in the general method *2.6.12*, but using broth medium A in place of buffered sodium chloride-peptone solution pH 7.0, homogenise and incubate at 35-37 °C for 18-24 h. Transfer 1 ml of the enrichment culture to 10 ml of broth medium I and incubate at 41-43 °C for 18-24 h. Subculture on at least 2 different agar media chosen from among agar medium J, agar medium K and agar medium L. Incubate at 35-37 °C for 18-72 h. The probable presence of salmonellae is indicated by the growth of cultures having the following appearance:

– agar medium J: well-developed, colourless colonies;

– agar medium K: well-developed, red colonies, with or without black centres;

– agar medium L: small, transparent, colourless or pink or opaque-white colonies, often surrounded by a pink or red zone.

Transfer separately a few of the suspect colonies to agar medium M in tubes, using surface and deep inoculation. The presence of salmonellae is provisionally confirmed if in the deep inoculation but not in the surface culture there is a change of colour from red to yellow and usually a formation of gas, with or without production of hydrogen sulphide in the agar. Precise confirmation may be carried out by appropriate biochemical and serological tests. The product passes the test if colonies of the type described do not appear or if the confirmatory biochemical and serological tests are negative.

Pseudomonas aeruginosa

Prepare the product to be examined as described in the general method *2.6.12* and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate 100 ml of broth medium A, homogenise and incubate at 35-37 °C for 18-48 h. Subculture on a plate of agar medium N and incubate at 35-37 °C for 18-72 h. If no growth of micro-organisms is detected, the product passes the test. If growth of gram-negative rods occurs, transfer some material of morphologically different, isolated colonies to broth medium A and incubate at 41-43 °C for 18-24 h. The product passes the test if no growth occurs at 41-43 °C.

When testing transdermal patches, filter 50 ml of preparation A as described in the general method *2.6.12* through a sterile filter membrane and place in 100 ml of broth medium A and incubate at 35-37 °C for 18-48 h. After incubation, spread on agar medium N.

Staphylococcus aureus

Prepare the product to be examined as described in the general method *2.6.12* and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate 100 ml of broth medium A, homogenise and incubate at 35-37 °C for 18-48 h. Subculture on a plate of agar medium O and incubate at 35-37 °C for 18-72 h. Black colonies of gram-positive cocci surrounded by a clear zone indicate the presence of *S. aureus*. Confirmation may be effected by suitable biochemical tests such as the coagulase test and the deoxyribonuclease test. The product passes the test if colonies of the type described do not appear on agar medium O or if the confirmatory biochemical tests are negative.

When testing transdermal patches, filter 50 ml of preparation A as described in the general method *2.6.12* through a sterile filter membrane and place in 100 ml of broth medium A and incubate at 35-37 °C for 18-48 h. After incubation, spread on agar medium O.

Nutritive and selective properties of the media and validity of the test

The tests described hereafter must be performed at least on each lot of dehydrated media.

Proceed as follows. Grow the following test strains separately, in tubes containing suitable media such as those indicated, at 30-35 °C for 18-24 h:

Staphylococcus aureus	such as ATCC 6538 (NCIMB 9518, CIP 4.83): broth medium A;
Pseudomonas aeruginosa	such as ATCC 9027 (NCIMB 8626, CIP 82.118): broth medium A;
Escherichia coli	such as ATCC 8739 (NCIMB 8545, CIP 53.126): broth medium A;
Salmonella typhimurium	no strain number is recommended (a salmonella not pathogenic for man, such as *Salmonella abony* (NCTC 6017, CIP 80.39), may also be used): broth medium A.

Dilute portions of each of the cultures using buffered sodium chloride-peptone solution pH 7.0 to make test suspensions containing about 1000 viable micro-organisms per millilitre. Mix equal volumes of each suspension and use 0.4 ml (approximately 100 micro-organisms of each strain) as an inoculum in tests for *S. aureus, P. aeruginosa, E. coli* and *Salmonella* in the presence and in the absence of the product to be examined. A positive result for the respective micro-organisms must be obtained.

Clostridia

The tests described below are intended for distinct purposes. The first method is intended for products where exclusion of pathogenic clostridia is essential and it is necessary to test for their absence. The products generally have a low total count. The second method is a semi-quantitative test for *Clostridium perfringens* and is intended for products where the level of this species is a criterion of quality.

1. *Test for Clostridia*

Prepare the product to be examined as described in the general method *2.6.12*. Take 2 equal portions corresponding to 1 g or 1 ml of the product to be examined. Heat 1 portion to 80 °C for 10 min and cool rapidly. Do not heat the other portion. Transfer 10 ml of each of the homogenised portions to 2 containers (38 mm × 200 mm, or other suitable containers) containing 100 ml of medium P. Incubate under anaerobic conditions at 35-37 °C for 48 h. After incubation, make subcultures from each tube on medium Q to which gentamicin has been added and incubate under anaerobic conditions at 35-37 °C for 48 h. If no growth of micro-organisms is detected, the product passes the test.

Where growth occurs, subculture each distinct colony form on culture medium Q, without gentamicin, and incubate in both aerobic and anaerobic conditions. The occurrence of only anaerobic growth of gram-positive bacilli (with or without endospores) giving a negative catalase reaction indicates the presence of *Clostridium* spp. Compare, if necessary, colony morphology on the 2 plates and apply the catalase test to eliminate aerobic and facultatively anaerobic *Bacillus* spp. that give a positive catalase reaction. This test may be applied to discrete colonies on agar, or indirectly following transfer to a glass slide, by application of a drop of *dilute hydrogen peroxide solution R*. The formation of gas bubbles indicates a positive catalase reaction.

2. *Count of Clostridium perfringens*

Prepare the product to be examined as described in the general method *2.6.12*, and prepare 1:100 and 1:1000 dilutions in buffered sodium chloride-peptone solution pH 7.0. Determine the most probable number of bacteria as described under total viable aerobic count *2.6.12*, using culture medium R in tubes or other suitable containers with a small Durham tube. Mix with minimum shaking and

incubate at 45.5-46.5 °C for 24-48 h. The containers showing a blackening due to iron sulphide and abundant formation of gas in the Durham tube (at least 1/10 of the volume) indicate the presence of *Cl. perfringens*. Estimate the most probable number of *Cl. perfringens* by means of Table 2.6.13.-2.

Controls

Use the following test strains:

For method 1: *Clostridium sporogenes*, e.g. ATCC 19404 (NCTC 532) or CIP 79.3;

For method 2: *Clostridium perfringens*, e.g. ATCC 13124 (NCIMB 6125, NCTC 8237, CIP 103 409).

If necessary, combine with *Cl. sporogenes* to check selectivity and anaerobic conditions.

Table 2.6.13.-2 – *Most-probable-number (MPN) values of bacteria*

3 tubes at each level of dilution							
Number of positive tubes			MPN per gram	Category*		95 per cent confidence limits	
0.1 g	0.01 g	0.001 g		1	2		
0	0	0	< 3			–	–
0	1	0	3		x	< 1	17
1	0	0	3	x		1	21
1	0	1	7		x	2	27
1	1	0	7	x		2	28
1	2	0	11		x	4	35
2	0	0	9	x		2	38
2	0	1	14		x	5	48
2	1	0	15	x		5	50
2	1	1	20		x	8	61
2	2	0	21	x		8	63
3	0	0	23	x		7	129
3	0	1	38	x		10	180
3	1	0	43	x		20	210
3	1	1	75	x		20	280

3	2	1	150	x		50	510
3	2	2	210		x	80	640
3	3	0	240	x		100	1400
3	3	1	460	x		200	2400
3	3	2	1100	x		300	4800
3	3	3	> 1100			–	–

* Category 1: normal results, obtained in 95 per cent of cases.

Category 2: less likely results, obtained in only 4 per cent of cases. These are not to be used for important decisions. Results that are even less likely than those of category 2 are not mentioned and are always unacceptable.

The following section is published for information.

RECOMMENDED SOLUTION AND CULTURE MEDIA

The following solution and culture media have been found to be satisfactory for the purposes for which they are prescribed in the test for microbial contamination in the Pharmacopoeia. Other media may be used if they have similar nutritive and selective properties for the micro-organisms to be tested for.

Buffered sodium chloride-peptone solution pH 7.0

Potassium dihydrogen phosphate	3.6 g
Disodium hydrogen phosphate dihydrate	7.2 g, equivalent to 0.067 M phosphate
Sodium chloride	4.3 g
Peptone (meat or casein)	1.0 g
Purified water	1000 ml

To this solution surface-active agents or inactivators of antimicrobial agents may be added, such as:

Polysorbate 80	1-10 g/l

Sterilise by heating in an autoclave at 121 °C for 15 min.

Broth medium A (Casein soya bean digest broth)

Pancreatic digest of casein	17.0 g
Papaic digest of soya bean	3.0 g
Sodium chloride	5.0 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate	2.5 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min.

Agar medium B (Casein soya bean digest agar)

Pancreatic digest of casein	15.0 g
Papaic digest of soya bean	5.0 g
Sodium chloride	5.0 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min.

Agar medium C (Sabouraud-glucose agar with antibiotics)

Peptones (meat and casein)	10.0 g
Glucose monohydrate	40.0 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 5.6 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min. Immediately before use, add 0.10 g of benzylpenicillin sodium and 0.10 g of tetracycline per litre of medium as sterile solutions or, alternatively, add 50 mg of chloramphenicol per litre of medium before sterilisation.

Broth medium D (Lactose monohydrate broth)

Beef extract	3.0 g
Pancreatic digest of gelatin	5.0 g
Lactose monohydrate	5.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 6.9 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min and cool immediately.

Enrichment broth medium E (Enterobacteria enrichment broth-Mossel)

Pancreatic digest of gelatin	10.0 g
Glucose monohydrate	5.0 g
Dehydrated ox bile	20.0 g

Potassium dihydrogen phosphate	2.0 g
Disodium hydrogen phosphate dihydrate	8.0 g
Brilliant green	15 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.2 ± 0.2. Heat at 100 °C for 30 min and cool immediately.

Agar medium F (Crystal violet, neutral red, bile agar with glucose)

Yeast extract	3.0 g
Pancreatic digest of gelatin	7.0 g
Bile salts	1.5 g
Lactose monohydrate	10.0 g
Sodium chloride	5.0 g
Glucose monohydrate	10.0 g
Agar	15.0 g
Neutral red	30 mg
Crystal violet	2 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.4 ± 0.2. Heat to boiling; do not heat in an autoclave.

Broth medium G (MacConkey broth)

Pancreatic digest of gelatin	20.0 g
Lactose monohydrate	10.0 g
Dehydrated ox bile	5.0 g
Bromocresol purple	10 mg
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min.

Agar medium H (MacConkey agar)

Pancreatic digest of gelatin	17.0 g
Peptones (meat and casein)	3.0 g
Lactose monohydrate	10.0 g
Sodium chloride	5.0 g
Bile salts	1.5 g
Agar	13.5 g
Neutral red	30.0 mg
Crystal violet	1 mg
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.1 ± 0.2. Boil for 1 min with constant shaking then sterilise by heating in an autoclave at 121 °C for 15 min.

Broth medium I (Tetrathionate bile brilliant green broth)

Peptone	8.6 g
Ox bile, dried	8.0 g
Sodium chloride	6.4 g
Calcium carbonate	20.0 g
Potassium tetrathionate	20.0 g
Brilliant green	70 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.0 ± 0.2. Heat just to boiling. Do not re-heat.

Agar medium J (Deoxycholate citrate agar)

Beef extract	10.0 g
Meat peptone	10.0 g
Lactose monohydrate	10.0 g
Sodium citrate	20.0 g
Ferric citrate	1.0 g
Sodium deoxycholate	5.0 g
Agar	13.5 g
Neutral red	20 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.3 ± 0.2. Heat gently to boiling and boil for 1 min, cool to 50 °C and pour into Petri dishes. Do not heat in an autoclave.

Agar medium K (Xylose, lysine, deoxycholate agar)

Xylose	3.5 g
L-Lysine	5.0 g
Lactose monohydrate	7.5 g
Sucrose	7.5 g
Sodium chloride	5.0 g
Yeast extract	3.0 g
Phenol red	80 mg
Agar	13.5 g
Sodium deoxycholate	2.5 g
Sodium thiosulphate	6.8 g
Ferric ammonium citrate	0.8 g
Purified water	1000 ml

Adjust the pH so that after heating it is 7.4 ± 0.2. Heat just to boiling, cool to 50 °C and pour into Petri dishes. Do not heat in an autoclave.

Agar medium L (Brilliant green, phenol red, lactose monohydrate, sucrose agar)

Peptones (meat and casein)	10.0 g
Yeast extract	3.0 g
Sodium chloride	5.0 g
Lactose monohydrate	10.0 g
Sucrose	10.0 g
Agar	20.0 g
Phenol red	80 mg
Brilliant green	12.5 mg
Purified water	1000 ml

Heat to boiling for 1 min. Adjust the pH so that after sterilisation it is 6.9 ± 0.2. Immediately before use, sterilise by heating in an autoclave at 121 °C for 15 min, cool to 50 °C and pour into Petri dishes.

Agar medium M (Triple sugar, iron agar)

Beef extract	3.0 g
Yeast extract	3.0 g
Peptones (casein and beef)	20.0 g
Sodium chloride	5.0 g
Lactose monohydrate	10.0 g
Sucrose	10.0 g

Glucose monohydrate	1.0 g
Ferric ammonium citrate	0.3 g
Sodium thiosulphate	0.3 g
Phenol red	25 mg
Agar	12.0 g
Purified water	1000 ml

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.4 ± 0.2. Fill into tubes to 1/3 of their height, sterilise by heating in an autoclave at 121 °C for 15 min and allow to cool in a position that gives a deep portion and a sloping surface.

Agar medium N (Cetrimide agar)

Pancreatic digest of gelatin	20.0 g
Magnesium chloride	1.4 g
Dipotassium sulphate	10.0 g
Cetrimide	0.3 g
Agar	13.6 g
Purified water	1000 ml
Glycerol	10.0 ml

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.2 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min.

Agar medium O (Baird-Parker agar)

Pancreatic digest of casein	10.0 g
Beef extract	5.0 g
Yeast extract	1.0 g
Lithium chloride	5.0 g
Agar	20.0 g
Glycine	12.0 g
Sodium pyruvate	10.0 g
Purified water	950 ml

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 6.8 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min, cool to 45-50 °C and add 10 ml of a sterile 10 g/l solution of potassium tellurite and 50 ml of egg-yolk emulsion.

Medium P (Reinforced medium for clostridia)

Beef extract	10.0 g
Peptone	10.0 g
Yeast extract	3.0 g
Soluble starch	1.0 g
Glucose monohydrate	5.0 g
Cysteine hydrochloride	0.5 g
Sodium chloride	5.0 g
Sodium acetate	3.0 g
Agar	0.5 g
Purified water	1000 ml

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is about 6.8. Sterilise by heating in an autoclave at 121 °C for 15 min.

Medium Q (Columbia agar)

Pancreatic digest of casein	10.0 g
Meat peptic digest	5.0 g
Heart pancreatic digest	3.0 g
Yeast extract	5.0 g
Maize starch	1.0 g
Sodium chloride	5.0 g
Agar, according to gelling power	10.0-15.0 g
Purified water	1000 ml

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is 7.3 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min. Allow to cool to 45-50 °C; add, where necessary, gentamicin sulphate corresponding to 20 mg of gentamicin base and pour into Petri dishes.

Medium R (Lactose monohydrate sulphite medium)

Pancreatic digest of casein	5.0 g
Yeast extract	2.5 g
Sodium chloride	2.5 g
Lactose monohydrate	10.0 g
Cysteine hydrochloride	0.3 g
Purified water	1000 ml

Dissolve, adjust to pH 7.1 ± 0.1 and fill to 8 ml in 16 mm × 160 mm tubes containing a small Durham tube. Sterilise by heating in an autoclave at 121 °C for 15 min and store at 4 °C.

Before use, heat the medium for 5 min in a water-bath and cool. Add to each tube 0.5 ml of a 12 g/l solution of *sodium metabisulphite R* and 0.5 ml of a 10 g/l solution of ferric ammonium citrate, both solutions being freshly prepared and filtered through membranes (pore size: 0.45 µm).

Agar medium S (R2A)

Yeast extract	0.5 g
Proteose peptone	0.5 g
Casein hydrolysate	0.5 g
Glucose	0.5 g
Starch	0.5 g
Dipotassium hydrogen phosphate	0.3 g
Magnesium sulphate, anhydrous	0.024 g
Sodium pyruvate	0.3 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.2 ± 0.2. Sterilise by heating in an autoclave at 121 °C for 15 min.

NEUTRALISING AGENTS

Neutralising agents may be used to neutralise the activity of antimicrobial agents. They may be added to buffered sodium chloride-peptone solution pH 7.0, preferably before sterilisation. If utilised, their efficacy and non-toxicity towards micro-organisms are demonstrated.

A typical neutralising fluid has the following composition:

Polysorbate 80	30 g
Lecithin (egg)	3 g
Histidine hydrochloride	1 g

Peptone (meat or casein)	1 g
Sodium chloride	4.3 g
Potassium dihydrogen phosphate	3.6 g
Disodium hydrogen phosphate dihydrate	7.2 g
Purified water	1000 ml

Sterilise by heating in an autoclave at 121 °C for 15 min.

If the solution has insufficient neutralising capacity the concentration of polysorbate 80 or lecithin may be increased. Alternatively, the neutralisers mentioned in Table 2.6.13.-3 may be added.

Table 2.6.13.-3. – *Inactivators for antimicrobial agents to be added to buffered sodium chloride-peptone solution pH 7.0*

Type of antimicrobial agent	Inactivator	Concentration	Comment
Phenolics	Sodium laurilsulfate Polysorbate 80 and lecithin Egg yolk	4 g/l 30 g/l and 3 g/l 5 ml/l - 50 ml/l	Add after sterilisation of buffered sodium chloride-peptone solution pH 7.0
Organo-mercurials	Sodium thioglycolate	0.5 g/l - 5 g/l	
Halogens	Sodium thiosulphate	5 g/l	
Quaternary ammonium compounds	Egg yolk	5 ml/l - 50 ml/l	Add after sterilisation of buffered sodium chloride-peptone solution pH 7.0

B. HARMONISED METHOD

1. INTRODUCTION

The tests described hereafter will allow determination of the absence or limited occurrence of specified micro-organisms that may be detected under the conditions described.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2. GENERAL PROCEDURES

The preparation of samples is carried out as described in general chapter *2.6.12* (under section B, Harmonised method).

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralised as described in general chapter *2.6.12* (under section B, Harmonised method).

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated as described in general chapter *2.6.12* (under section B, Harmonised method).

3. GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA AND SUITABILITY OF THE TEST

The ability of the test to detect micro-organisms in the presence of the product to be tested must be established. Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

3-1. *PREPARATION OF TEST STRAINS*

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

3-1-1. **Aerobic micro-organisms**. Grow each of the bacterial test strains separately in casein soya bean digest broth or on casein soya bean digest agar at 30-35 °C for 18-24 h. Grow the test strain for *Candida albicans* separately on Sabouraud-dextrose agar or in Sabouraud-dextrose broth at 20-25 °C for 2-3 days.

– *Staphylococcus aureus* such as ATCC 6538, NCIMB 9518, CIP 4.83 or NBRC 13276;
– *Pseudomonas aeruginosa* such as ATCC 9027, NCIMB 8626, CIP 82.118 or NBRC 13275;
– *Escherichia coli* such as ATCC 8739, NCIMB 8545, CIP 53.126 or NBRC 3972;
– *Salmonella enterica* ssp. *enterica* serotype typhimurium, such as ATCC 14028 or, as an alternative, *Salmonella enterica* ssp. *enterica* serotype abony such as NBRC 100797, NCTC 6017 or CIP 80.39;
– *Candida albicans* such as ATCC 10231, NCPF 3179, IP 48.72 or NBRC 1594.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C.

3-1-2. **Clostridia**. Use *Clostridium sporogenes* such as ATCC 11437 (NBRC 14293, NCIMB 12343, CIP 100651) or ATCC 19404 (NCTC 532 or CIP 79.03) or NBRC 14293. Grow the clostridial test strain under anaerobic conditions in reinforced medium for clostridia at 30-35 °C for 24-48 h. As an alternative to preparing and then diluting down a fresh suspension of vegetative cells of *Cl. sporogenes*, a stable spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period.

3-2. *NEGATIVE CONTROL*

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms.

3-3. *GROWTH PROMOTION AND INHIBITORY PROPERTIES OF THE MEDIA*

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients.
Verify suitable properties of relevant media as described in Table 2.6.13.-4.

Test for growth promoting properties, liquid media: inoculate a portion of the appropriate medium with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Clearly visible growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Table 2.6.13.-4 – *Growth promoting, inhibitory and indicative properties of media*

	Medium	Property	Test strains
Test for bile-tolerant gram-negative bacteria	Enterobacteria enrichment broth-Mossel	Growth promoting	*E. coli* *P. aeruginosa*
		Inhibitory	*S. aureus*
	Violet red bile glucose agar	Growth promoting + indicative	*E. coli* *P. aeruginosa*
Test for *Escherichia coli*	MacConkey broth	Growth promoting	*E. coli*
		Inhibitory	*S. aureus*
	MacConkey agar	Growth promoting + indicative	*E. coli*
Test for *Salmonella*	Rappaport Vassiliadis *Salmonella* enrichment broth	Growth promoting	*Salmonella enterica* ssp. *enterica* serotype typhimurium or *Salmonella enterica* ssp. *enterica* serotype abony
		Inhibitory	*S. aureus*
	Xylose, lysine, deoxycholate agar	Growth promoting + indicative	*Salmonella enterica* ssp. *enterica* serotype typhimurium or *Salmonella enterica* ssp. *enterica* serotype abony
		Indicative	*E. coli*
Test for *Pseudomonas aeruginosa*	Cetrimide agar	Growth promoting	*P. aeruginosa*
		Inhibitory	*E. coli*
Test for *Staphylococcus aureus*	Mannitol salt agar	Growth promoting + indicative	*S. aureus*
		Inhibitory	*E. coli*
Test for clostridia	Reinforced medium for clostridia	Growth promoting	*Cl. sporogenes*
	Columbia agar	Growth promoting	*Cl. sporogenes*
Test for *Candida albicans*	Sabouraud dextrose broth	Growth promoting	*C. albicans*
	Sabouraud dextrose agar	Growth promoting + indicative	*C. albicans*

Test for growth promoting properties, solid media: perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Test for inhibitory properties, liquid or solid media: inoculate the appropriate medium with at least 100 CFU of the appropriate micro-organism. Incubate at the specified temperature for not less than the longest period of time specified in the test. No growth of the test micro-organism occurs.

Test for indicative properties: perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium.

3-4. *SUITABILITY OF THE TEST METHOD*

For each product to be tested, perform the sample preparation as described in the relevant paragraph in section 4. Add each test strain at the time of mixing, in the prescribed growth medium. Inoculate the test strains individually. Use a number of micro-organisms equivalent to not more than 100 CFU in the inoculated test preparation. Perform the test as described in the relevant paragraph in section 4 using the shortest incubation period prescribed.

The specified micro-organisms must be detected with the indication reactions as described in section 4.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see 4-5-3 of general chapter *2.6.12* (under section B, Harmonised method)).

If for a given product the antimicrobial activity with respect to a micro-organism for which testing is prescribed cannot be neutralised, then it is to be assumed that the inhibited micro-organism will not be present in the product.

4. TESTING OF PRODUCTS

4-1. *BILE-TOLERANT GRAM-NEGATIVE BACTERIA*

4-1-1. **Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12* (under section B, Harmonised method), but using casein soya bean digest broth as the chosen diluent, mix and incubate at 20-25 °C for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the organisms (usually 2 h but not more than 5 h).

4-1-2. **Test for absence**. Unless otherwise prescribed, use the volume corresponding to 1 g of the product, as prepared in 4-1-1, to inoculate enterobacteria enrichment broth-Mossel. Incubate at 30-35 °C for 24-48 h. Subculture on plates of violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

The product complies with the test if there is no growth of colonies.

4-1-3. **Quantitative test**

4-1-3-1. *Selection and subculture*. Inoculate suitable quantities of enterobacteria enrichment broth-Mossel with the preparation as described under 4-1-1 and/or dilutions of it containing respectively 0.1 g, 0.01 g and 0.001 g (or 0.1 ml, 0.01 ml and 0.001 ml) of the product to be examined. Incubate at 30-35 °C for 24-48 h. Subculture each of the cultures on a plate of violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

4-1-3-2. *Interpretation*. Growth of colonies constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result. Determine from Table 2.6.13.-5 the probable number of bacteria.

Table 2.6.13.-5 – *Interpretation of results*

Results for each quantity of product			Probable number of bacteria per gram or millilitre of product
0.1 g or 0.1 ml	0.01 g or 0.01 ml	0.001 g or 0.001 ml	
+	+	+	$> 10^3$
+	+	−	$< 10^3$ and $> 10^2$
+	−	−	$< 10^2$ and > 10
−	−	−	< 10

4-2. *ESCHERICHIA COLI*

4-2-1. **Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12* (under section B, Harmonised method), and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

4-2-2. **Selection and subculture**. Shake the container, transfer 1 ml of casein soya bean digest broth to 100 ml of MacConkey broth and incubate at 42-44 °C for 24-48 h. Subculture on a plate of MacConkey agar at 30-35 °C for 18-72 h.

4-2-3. **Interpretation**. Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

The product complies with the test if no colonies are present or if the identification tests are negative.

4-3. *SALMONELLA*

4-3-1. **Sample preparation and pre-incubation**. Prepare the product to be examined as described in general chapter *2.6.12* (under section B, Harmonised method), and use the quantity corresponding to not less than 10 g or 10 ml to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

4-3-2. **Selection and subculture**. Transfer 0.1 ml of casein soya bean digest broth to 10 ml of Rappaport Vassiliadis *Salmonella* enrichment broth and incubate at 30-35 °C for 18-24 h. Subculture on plates of xylose, lysine, deoxycholate agar. Incubate at 30-35 °C for 18-48 h.

4-3-3. **Interpretation**. The possible presence of *Salmonella* is indicated by the growth of well-developed, red colonies, with or without black centres. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-4. *PSEUDOMONAS AERUGINOSA*

4-4-1. **Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12* (under section B, Harmonised method), and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. When testing transdermal patches, filter the volume of sample corresponding to 1 patch of the preparation described in general chapter *2.6.12* (4-5-1, under section B, Harmonised method) through a sterile filter membrane and place in 100 ml of casein soya bean digest broth. Incubate at 30-35 °C for 18-24 h.

4-4-2. **Selection and subculture**. Subculture on a plate of cetrimide agar and incubate at 30-35 °C for 18-72 h.

4-4-3. **Interpretation**. Growth of colonies indicates the possible presence of *P. aeruginosa*. This is confirmed by identification tests.

The product complies with the test if colonies are not present or if the confirmatory identification tests are negative.

4-5. *STAPHYLOCOCCUS AUREUS*

4-5-1. **Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12* (under section B, Harmonised method), and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. When testing transdermal patches, filter the volume of sample corresponding to 1 patch of the preparation described in general chapter *2.6.12* (4-5-1, under section B, Harmonised method) through a sterile filter membrane and place in 100 ml of casein soya bean digest broth. Incubate at 30-35 °C for 18-24 h.

4-5-2. **Selection and subculture**. Subculture on a plate of mannitol salt agar and incubate at 30-35 °C for 18-72 h.

4-5-3. **Interpretation**. The possible presence of *S. aureus* is indicated by the growth of yellow/white colonies surrounded by a yellow zone. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-6. *CLOSTRIDIA*

4-6-1. **Sample preparation and heat treatment**. Prepare the product to be examined as described in general chapter *2.6.12* (under section B, Harmonised method). Take 2 equal portions corresponding to not less than 1 g or 1 ml of the product to be examined. Heat 1 portion at 80 °C for 10 min and cool rapidly. Do not heat the other portion.

4-6-2. **Selection and subculture**. Transfer 10 ml of each of the mixed portions to 2 containers (38 mm × 200 mm, or other suitable containers) containing 100 ml of reinforced medium for clostridia. Incubate under anaerobic conditions at 30-35 °C for 48 h. After incubation, make subcultures from each tube on Columbia agar and incubate under anaerobic conditions at 30-35 °C for 48 h.

4-6-3. **Interpretation**. The occurrence of anaerobic growth of rods (with or without endospores) giving a negative catalase reaction indicates the presence of clostridia.

If no anaerobic growth of micro-organisms is detected on Columbia agar or the catalase test is positive, the product complies with the test.

4-7. *CANDIDA ALBICANS*

4-7-1. **Sample preparation and pre-incubation**. Prepare the product to be examined as described in general chapter *2.6.12* (under section B, Harmonised method), and use 10 ml or the quantity corresponding to not less than 1 g or 1 ml to inoculate 100 ml of Sabouraud-dextrose broth and mix. Incubate at 30-35 °C for 3-5 days.

4-7-2. **Selection and subculture**. Subculture on a plate of Sabouraud-dextrose agar and incubate at 30-35 °C for 24-48 h.

4-7-3. **Interpretation**. Growth of white colonies may indicate the presence of *C. albicans*. This is confirmed by identification tests.

The product complies with the test if such colonies are not present or if the confirmatory identification tests are negative.

The following section is given for information.

5. RECOMMENDED SOLUTIONS AND CULTURE MEDIA

The following solutions and culture media have been found to be satisfactory for the purposes for which they are prescribed in the test for microbial contamination in the Pharmacopoeia. Other media may be used if they have similar growth promoting and inhibitory properties.

Stock buffer solution. Place 34 g of potassium dihydrogen phosphate in a 1000 ml volumetric flask, dissolve in 500 ml of purified water, adjust to pH 7.2 ± 0.2 with sodium hydroxide, dilute to 1000.0 ml with purified water and mix. Dispense into containers and sterilise. Store at 2-8 °C.

Phosphate buffer solution pH 7.2. Prepare a mixture of stock buffer solution and purified water (1:800 *V/V*) and sterilise.

Buffered sodium chloride-peptone solution pH 7.0

Potassium dihydrogen phosphate	3.6 g
Disodium hydrogen phosphate dihydrate	7.2 g, equivalent to 0.067 M phosphate
Sodium chloride	4.3 g
Peptone (meat or casein)	1.0 g
Purified water	1000 ml

Sterilise in an autoclave using a validated cycle.

Casein soya bean digest broth

Pancreatic digest of casein	17.0 g
Papaic digest of soya bean	3.0 g
Sodium chloride	5.0 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate	2.5 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Casein soya bean digest agar

Pancreatic digest of casein	15.0 g
Papaic digest of soya bean	5.0 g
Sodium chloride	5.0 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Sabouraud-dextrose agar

Dextrose	40.0 g
Mixture of peptic digest of animal tissue and pancreatic digest of casein (1:1)	10.0 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Potato dextrose agar

Infusion from potatoes	200 g
Dextrose	20.0 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Sabouraud-dextrose broth

Dextrose	20.0 g
Mixture of peptic digest of animal tissue and pancreatic digest of casein (1:1)	10.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Enterobacteria enrichment broth-Mossel

Pancreatic digest of gelatin	10.0 g
Glucose monohydrate	5.0 g
Dehydrated ox bile	20.0 g
Potassium dihydrogen phosphate	2.0 g
Disodium hydrogen phosphate dihydrate	8.0 g
Brilliant green	15 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.2 ± 0.2 at 25 °C. Heat at 100 °C for 30 min and cool immediately.

Violet red bile glucose agar

Yeast extract	3.0 g
Pancreatic digest of gelatin	7.0 g
Bile salts	1.5 g
Sodium chloride	5.0 g
Glucose monohydrate	10.0 g
Agar	15.0 g
Neutral red	30 mg
Crystal violet	2 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.4 ± 0.2 at 25 °C. Heat to boiling; do not heat in an autoclave.

MacConkey broth

Pancreatic digest of gelatin	20.0 g
Lactose monohydrate	10.0 g
Dehydrated ox bile	5.0 g
Bromocresol purple	10 mg
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

MacConkey agar

Pancreatic digest of gelatin	17.0 g
Peptones (meat and casein)	3.0 g
Lactose monohydrate	10.0 g
Sodium chloride	5.0 g
Bile salts	1.5 g
Agar	13.5 g

Neutral red	30.0 mg
Crystal violet	1 mg
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.1 ± 0.2 at 25 °C. Boil for 1 min with constant shaking then sterilise in an autoclave using a validated cycle.

Rappaport Vassiliadis *Salmonella* enrichment broth

Soya peptone	4.5 g
Magnesium chloride hexahydrate	29.0 g
Sodium chloride	8.0 g
Dipotassium phosphate	0.4 g
Potassium dihydrogen phosphate	0.6 g
Malachite green	0.036 g
Purified water	1000 ml

Dissolve, warming gently. Sterilise in an autoclave using a validated cycle, at a temperature not exceeding 115 °C. The pH is to be 5.2 ± 0.2 at 25 °C after heating and autoclaving.

Xylose, lysine, deoxycholate agar

Xylose	3.5 g
L-Lysine	5.0 g
Lactose monohydrate	7.5 g
Sucrose	7.5 g
Sodium chloride	5.0 g
Yeast extract	3.0 g
Phenol red	80 mg
Agar	13.5 g
Sodium deoxycholate	2.5 g
Sodium thiosulphate	6.8 g
Ferric ammonium citrate	0.8 g
Purified water	1000 ml

Adjust the pH so that after heating it is 7.4 ± 0.2 at 25 °C. Heat to boiling, cool to 50 °C and pour into Petri dishes. Do not heat in an autoclave.

Cetrimide agar

Pancreatic digest of gelatin	20.0 g
Magnesium chloride	1.4 g
Dipotassium sulphate	10.0 g
Cetrimide	0.3 g
Agar	13.6 g
Purified water	1000 ml
Glycerol	10.0 ml

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.2 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Mannitol salt agar

Pancreatic digest of casein	5.0 g
Peptic digest of animal tissue	5.0 g
Beef extract	1.0 g
D-Mannitol	10.0 g
Sodium chloride	75.0 g
Agar	15.0 g
Phenol red	0.025 g
Purified water	1000 ml

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.4 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Reinforced medium for clostridia

Beef extract	10.0 g
Peptone	10.0 g
Yeast extract	3.0 g
Soluble starch	1.0 g
Glucose monohydrate	5.0 g
Cysteine hydrochloride	0.5 g
Sodium chloride	5.0 g
Sodium acetate	3.0 g
Agar	0.5 g
Purified water	1000 ml

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is 6.8 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Columbia agar

Pancreatic digest of casein	10.0 g
Meat peptic digest	5.0 g
Heart pancreatic digest	3.0 g
Yeast extract	5.0 g
Maize starch	1.0 g
Sodium chloride	5.0 g
Agar, according to gelling power	10.0-15.0 g
Purified water	1000 ml

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle. Allow to cool to 45-50 °C; add, where necessary, gentamicin sulphate corresponding to 20 mg of gentamicin base and pour into Petri dishes.

01/2008:20614

2.6.14. BACTERIAL ENDOTOXINS

The test for bacterial endotoxins is used to detect or quantify endotoxins of gram-negative bacterial origin using amoebocyte lysate from horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*). There are 3 techniques for this test: the gel-clot technique, which is based on gel formation; the turbidimetric technique, based on the development of turbidity after cleavage of an endogenous substrate; and the chromogenic technique, based on the development of colour after cleavage of a synthetic peptide-chromogen complex.

The following 6 methods are described in the present chapter:

Method A. Gel-clot method: limit test

Method B. Gel-clot method: semi-quantitative test

Method C. Turbidimetric kinetic method

Method D. Chromogenic kinetic method

Method E. Chromogenic end-point method

Method F. Turbidimetric end-point method

Proceed by any of the 6 methods for the test. In the event of doubt or dispute, the final decision is made based upon method A unless otherwise indicated in the monograph.

The test is carried out in a manner that avoids endotoxin contamination.

Apparatus

Depyrogenate all glassware and other heat-stable apparatus in a hot-air oven using a validated process. A commonly used minimum time and temperature is 30 minutes at 250 °C. If employing plastic apparatus, such as microtitre plates and pipette tips for automatic pipetters, use apparatus shown to be free of detectable endotoxin and of interfering effects for the test.

NOTE: In this chapter, the term 'tube' includes all types of receptacles, for example microtitre plate wells.

Preparation of the standard endotoxin stock solution

The standard endotoxin stock solution is prepared from an endotoxin reference standard that has been calibrated against the International Standard, for example *endotoxin standard BRP*.

Endotoxin is expressed in International Units (IU). The equivalence in IU of the International Standard is stated by the World Health Organisation.

NOTE: One International Unit (IU) of endotoxin is equal to one Endotoxin Unit (E.U.).

Follow the specifications in the package leaflet and on the label for preparation and storage of the standard endotoxin stock solution.

Preparation of the standard endotoxin solutions

After vigorously mixing the standard endotoxin stock solution, prepare appropriate serial dilutions of this solution using water for bacterial endotoxins test (water for BET).

Use the solutions as soon as possible to avoid loss of activity by adsorption.

Preparation of the test solutions

Prepare the test solutions by dissolving or diluting active substances or medicinal products using water for BET. Some substances or preparations may be more appropriately dissolved or diluted in other aqueous solutions. If necessary, adjust the pH of the test solution (or dilution thereof) so that the pH of the mixture of the lysate and test solution falls within the pH range specified by the lysate manufacturer. This usually applies to a product with a pH in the range of 6.0 to 8.0. The pH may be adjusted by the use of acid, base or a suitable buffer, as recommended by the lysate manufacturer. Acids and bases may be prepared from concentrates or solids with water for BET in containers free of detectable endotoxin. Buffers must be validated to be free of detectable endotoxin and interfering factors.

Determination of the Maximum Valid Dilution

The Maximum Valid Dilution (MVD) is the maximum allowable dilution of a sample at which the endotoxin limit can be determined. Determine the MVD using the following formulae:

$$\frac{\text{endotoxin limit} \times \text{concentration of test solution}}{\lambda}$$

Endotoxin limit: the endotoxin limit for active substances administered parenterally, defined on the basis of dose, is equal to:

$$\frac{K}{M}$$

K = threshold pyrogenic dose of endotoxin per kilogram of body mass in a single hour period,

M = maximum recommended dose of product per kilogram of body mass in a single hour period.

The endotoxin limit for active substances administered parenterally is specified in units such as IU/ml, IU/mg, IU/Unit of biological activity, etc., in monographs.

Concentration of test solution:

– in mg/ml if the endotoxin limit is specified by mass (IU/mg),

– in Units/ml if the endotoxin limit is specified by unit of biological activity (IU/Unit),

– in ml/ml if the endotoxin limit is specified by volume (IU/ml).

λ = the labelled lysate sensitivity in the gel-clot technique (IU/ml) or the lowest point used in the standard curve of the turbidimetric or chromogenic techniques.

GEL-CLOT TECHNIQUE (METHODS A AND B)

The gel-clot technique allows detection or quantification of endotoxins and is based on clotting of the lysate in the presence of endotoxins. The concentration of endotoxins required to cause the lysate to clot under standard conditions is the labelled lysate sensitivity. To ensure both the precision and validity of the test, confirm the labelled lysate sensitivity and perform the test for interfering factors as described under *1. Preparatory testing*.

1. PREPARATORY TESTING

(i) Confirmation of the labelled lysate sensitivity

Confirm in 4 replicates the labelled sensitivity λ, expressed in IU/ml, of the lysate solution prior to use in the test. Confirmation of the lysate sensitivity is carried out when a new batch of lysate is used or when there is any change in the experimental conditions which may affect the outcome of the test.

Prepare standard solutions of at least 4 concentrations equivalent to 2λ, λ, 0.5λ and 0.25λ by diluting the standard endotoxin stock solution with water for BET.

Mix a volume of the lysate solution with an equal volume of 1 of the standard solutions (such as 0.1 ml aliquots) in each tube. When single test vials or ampoules containing lyophilised lysate are employed, add solutions directly to the vial or ampoule. Incubate the reaction mixture for a constant period according to the recommendations of the lysate manufacturer (usually at 37 ± 1 °C for 60 ± 2 min), avoiding vibration. Test the integrity of the gel: for tubes, take each tube in turn directly from the incubator and invert it through approximately 180° in one smooth motion. If a firm gel has formed that remains in place upon inversion, record the result as positive. A result is negative if an intact gel is not formed.

The test is not valid unless the lowest concentration of the standard solutions shows a negative result in all replicate tests.

The end-point is the last positive result in the series of decreasing concentrations of endotoxin. Calculate the mean value of the logarithms of the end-point concentrations and then the antilogarithm of the mean value using the following expression:

$$\text{Geometric mean end-point concentration} = \text{antilog}\frac{\sum e}{f}$$

$\sum e$ = sum of the log end-point concentrations of the dilution series used,

f = number of replicates.

The geometric mean end-point concentration is the measured sensitivity of the lysate solution (IU/ml). If this is not less than 0.5λ and not more than 2λ, the labelled sensitivity is confirmed and is used in the tests performed with this lysate.

(ii) Test for interfering factors

Prepare solutions A, B, C and D as shown in Table 2.6.14.-1, and use the test solutions at a dilution less than the MVD, not containing any detectable endotoxins, operating as described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

The geometric mean end-point concentrations of solutions B and C are determined using the expression described in 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

The test for interfering factors is repeated when any changes are made to the experimental conditions that are likely to influence the result of the test.

The test is not valid unless all replicates of solutions A and D show no reaction and the result of solution C confirms the labelled lysate sensitivity.

If the sensitivity of the lysate determined with solution B is not less than 0.5λ and not greater than 2λ, the test solution does not contain interfering factors under the experimental conditions used. Otherwise, the solution interferes with the test.

If the preparation being examined interferes with the test at a dilution less than the MVD, repeat the test for interfering factors using a greater dilution, not exceeding the MVD. The use of a more sensitive lysate permits a greater dilution of the preparation being examined and this may contribute to the elimination of interference.

Interference may be overcome by suitable treatment, such as filtration, neutralisation, dialysis or heat treatment. To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, repeat the test for interfering factors using the preparation being examined to which the standard endotoxin has been added and which has then been submitted to the chosen treatment.

2. LIMIT TEST (METHOD A)

(i) Procedure

Prepare solutions A, B, C and D as shown in Table 2.6.14.-2, and perform the test on these solutions following the procedure described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

Table 2.6.14.-2

Solution	Endotoxin concentration/ Solution to which endotoxin is added	Number of replicates
A	None/Diluted test solution	2
B	2λ/Diluted test solution	2
C	2λ/Water for BET	2
D	None/Water for BET	2

Prepare solution A and solution B (positive product control) using a dilution not greater than the MVD and treatments as described in 1. Preparatory testing, (ii) Test for interfering factors. Solutions B and C (positive controls) contain the standard endotoxin at a concentration corresponding to twice the labelled lysate sensitivity. Solution D (negative control) consists of water for BET.

(ii) Interpretation

The test is not valid unless both replicates of the 2 positive control solutions B and C are positive and those of the negative control solution D are negative.

The preparation being examined complies with the test when a negative result is found for both replicates of solution A.

When a positive result is found for both replicates of solution A:

- if the preparation being examined is diluted to the MVD, it does not comply with the test,
- if the preparation being examined is diluted to a dilution less than the MVD, the test is repeated at a dilution not greater than the MVD.

Repeat the test if a positive result is found for one replicate of solution A and a negative result is found for the other. The preparation being examined complies with the test if a negative result is found for both replicates of solution A in the repeat test.

Table 2.6.14.-1

Solution	Endotoxin concentration/ Solution to which endotoxin is added	Diluent	Dilution factor	Initial endotoxin concentration	Number of replicates
A	None/Test solution	-	-	-	4
B	2λ/Test solution	Test solution	1	2λ	4
			2	1λ	4
			4	0.5λ	4
			8	0.25λ	4
C	2λ/Water for BET	Water for BET	1	2λ	2
			2	1λ	2
			4	0.5λ	2
			8	0.25λ	2
D	None/Water for BET	-	-	-	2

Solution A = solution of the preparation being examined that is free of detectable endotoxins.

Solution B = test for interference.

Solution C = control of the labelled lysate sensitivity.

Solution D = negative control (water for BET).

3. SEMI-QUANTITATIVE TEST (METHOD B)

(i) Procedure

The test quantifies bacterial endotoxins in the test solution by titration to an end-point. Prepare solutions A, B, C and D as shown in Table 2.6.14.-3, and test these solutions according to the procedure described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

(ii) Calculation and interpretation

The test is not valid unless the following 3 conditions are met:

(a) both replicates of solution D (negative control) are negative,

(b) both replicates of solution B (positive product control) are positive,

(c) the geometric mean end-point concentration of solution C is in the range of 0.5λ to 2λ.

To determine the endotoxin concentration of solution A, calculate the end-point concentration for each replicate series of dilutions by multiplying each end-point dilution factor by λ.

The endotoxin concentration in the test solution is the geometric mean end-point concentration of the replicates (see the expression given under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity). If the test is conducted with a diluted test solution, calculate the concentration of endotoxin in the original solution by multiplying the result by the dilution factor.

If none of the dilutions of the test solution is positive in a valid test, record the endotoxin concentration as less than λ (or, if a diluted sample was tested, as less than λ × the lowest dilution factor of the sample). If all dilutions are positive, the endotoxin concentration is recorded as equal to or greater than the greatest dilution factor multiplied by λ (e.g. in Table 2.6.14.-3, the initial dilution factor × 8 × λ).

The preparation meets the requirements of the test if the endotoxin concentration is less than that specified in the individual monograph.

PHOTOMETRIC TECHNIQUES (METHODS C, D, E AND F)

1. TURBIDIMETRIC TECHNIQUE (METHODS C AND F)

This technique is a photometric test to measure the increase in turbidity. Based on the test principle employed, this technique is classified as being the end-point-turbidimetric test or the kinetic-turbidimetric test.

The end-point-turbidimetric test (Method F) is based on the quantitative relationship between the endotoxin concentration and the turbidity (absorbance or transmission) of the reaction mixture at the end of an incubation period.

The kinetic-turbidimetric test (Method C) is a method to measure either the time (onset time) needed for the reaction mixture to reach a predetermined absorbance, or the rate of turbidity development.

The test is carried out at the incubation temperature recommended by the lysate manufacturer (usually 37 ± 1 °C).

2. CHROMOGENIC TECHNIQUE (METHODS D AND E)

This technique is used to measure the chromophore released from a suitable chromogenic peptide by the reaction of endotoxins with the lysate. Depending on the test principle employed, this technique is classified as being the end-point-chromogenic test or the kinetic-chromogenic test.

The end-point-chromogenic test (Method E) is based on the quantitative relationship between the endotoxin concentration and the quantity of chromophore released at the end of an incubation period.

The kinetic-chromogenic test (Method D) measures either the time (onset time) needed for the reaction mixture to reach a predetermined absorbance, or the rate of colour development.

The test is carried out at the incubation temperature recommended by the lysate manufacturer (usually 37 ± 1 °C).

3. PREPARATORY TESTING

To assure the precision or validity of the turbidimetric and chromogenic tests, preparatory tests are conducted to assure that the criteria for the standard curve are satisfied and that the test solution does not interfere with the test.

Validation of the test method is required when any changes are made to the experimental conditions that are likely to influence the result of the test.

(i) Assurance of criteria for the standard curve

Using the standard endotoxin solution, prepare at least 3 endotoxin concentrations to generate the standard curve. Perform the test using at least 3 replicates of each standard endotoxin solution as recommended by the lysate manufacturer (volume ratios, incubation time, temperature, pH, etc.).

If the desired range is greater than 2 log in the kinetic methods, additional standards must be included to bracket each log increase in the range of the standard curve.

Table 2.6.14.-3

Solution	Endotoxin concentration/ Solution to which endotoxin is added	Diluent	Dilution factor	Initial endotoxin concentration	Number of replicates
A	None/Test solution	Water for BET	1	-	2
			2	-	2
			4	-	2
			8	-	2
B	2λ/Test solution		1	2λ	2
C	2λ/Water for BET	Water for BET	1	2λ	2
			2	1λ	2
			4	0.5λ	2
			8	0.25λ	2
D	None/Water for BET	-	-	-	2

Solution A = test solution at the dilution, not exceeding the MVD, with which the test for interfering factors was carried out. Subsequent dilution of the test solution must not exceed the MVD. Use water for BET to make two dilution series of 1, 1/2, 1/4 and 1/8, relative to the dilution with which the test for interfering factors was carried out. Other dilutions may be used as appropriate.

Solution B = solution A containing standard endotoxin at a concentration of 2λ (positive product control).

Solution C = 2 series of water for BET containing the standard endotoxin at concentrations of 2λ, λ, 0.5λ and 0.25λ.

Solution D = water for BET (negative control).

The absolute value of the correlation coefficient, | r |, must be greater than or equal to 0.980, for the range of endotoxin concentrations indicated by the lysate manufacturer.

(ii) Test for interfering factors

Select an endotoxin concentration at or near the middle of the endotoxin standard curve.

Prepare solutions A, B, C and D as shown in Table 2.6.14.-4. Perform the test on at least 2 replicates of these solutions as recommended by the lysate manufacturer (volume of test solution and lysate solution, volume ratio of test solution to lysate solution, incubation time, etc.).

Table 2.6.14.-4.

Solution	Endotoxin concentration	Solution to which endotoxin is added	Number of replicates
A	None	Test solution	Not less than 2
B	Middle concentration of the standard curve	Test solution	Not less than 2
C	At least 3 concentrations (lowest concentration is designated λ)	Water for BET	Each concentration not less than 2
D	None	Water for BET	Not less than 2

Solution A = test solution, that may be diluted not to exceed the MVD.

Solution B = preparation to be examined at the same dilution as solution A, containing added endotoxin at a concentration equal to or near the middle of the standard curve.

Solution C = standard endotoxin solution at the concentrations used in the validation of the method as described under 3. Preparatory testing, (i) Assurance of criteria for the standard curve (positive controls.

Solution D = water for BET (negative control).

Calculate the mean recovery of the added endotoxin by subtracting the mean endotoxin concentration in the solution (if any) from that in the solution containing the added endotoxin.

The test solution is considered free of interfering factors if under the conditions of the test, the measured concentration of the endotoxin added to the test solution is within 50-200 per cent of the known added endotoxin concentration, after subtraction of any endotoxin detected in the solution without added endotoxin.

When the endotoxin recovery is out of the specified ranges, the interfering factors must be removed as described in the section Gel-clot technique, under 1. Preparatory testing, (ii) Test for interfering factors. The efficiency of the treatment is verified by repeating the test for interfering factors.

4. TEST

(i) Procedure

Follow the procedure described in 3. Preparatory testing, (ii) Test for interfering factors.

(ii) Calculation

Calculate the endotoxin concentration of each replicate of solution A using the standard curve generated by the series of positive controls, solution C.

The test is not valid unless the following 3 requirements are met:

(a) the result obtained with solution D (negative control) does not exceed the limit of the blank value required in the description of the lysate employed,

(b) the results obtained with the series of positive controls, solution C, comply with the requirements for validation defined under 3. Preparatory testing, (i) Assurance of criteria for the standard curve,

(c) the endotoxin recovery, calculated from the endotoxin concentration found in solution B after subtracting the endotoxin concentration found in solution A, is within the range of 50-200 per cent.

(iii) Interpretation

The preparation being examined complies with the test if the mean endotoxin concentration of the replicates of solution A, after correction for dilution and concentration, is less than the endotoxin limit for the product.

5. REAGENTS

(i) Lysate solution

Dissolve amoebocyte lysate in water for BET or in a buffer, as recommended by the lysate manufacturer, by gentle stirring. Store the reconstituted lysate, refrigerated or frozen, as indicated by the manufacturer.

(ii) Amoebocyte lysate

Amoebocyte lysate is a lyophilised product obtained from amoebocyte lysate from Horseshoe Crab (*Limulus polyphemus* or *Tachypleus tridentatus*). This reagent refers only to a product manufactured in accordance with the regulations of the competent authority.

Amoebocyte lysate reacts with some β-glucans in addition to endotoxins. Amoebocyte lysate preparations which do not react with glucans are available; they are prepared by removing from amoebocyte lysate the G factor, which reacts with glucans, or by inhibiting the G factor reacting system of amoebocyte lysate. These preparations may be used for endotoxin testing in the presence of glucans.

(iii) Water for BET (water for bacterial endotoxins test)

Water for BET is *water for injections R* or water produced by other procedures that shows no reaction with the lysate employed at the detection limit of the reagent.

The following section is published for information.

Test for bacterial endotoxins: guidelines

1. INTRODUCTION

Endotoxins from gram-negative bacteria are the most common cause of toxic reactions resulting from contamination of pharmaceutical products with pyrogens; their pyrogenic activity is much higher than that of most other pyrogenic substances. These endotoxins are lipo-polysaccharides. Although there are a small number of pyrogens which possess a different structure, the conclusion is generally justified that the absence of bacterial endotoxins in a product implies the absence of pyrogenic components, provided the presence of non-endotoxin pyrogenic substances can be ruled out.

The presence of endotoxins in a product may be masked by factors interfering with the reaction between the endotoxins and the amoebocyte lysate. Hence, the analyst who wishes to replace the rabbit pyrogen test required in a pharmacopoeial monograph by a test for bacterial endotoxins has to demonstrate that a valid test can be carried out on the product concerned; this may entail a procedure for removing interfering factors.

As indicated in the test for bacterial endotoxins, information must be available on the 2 following aspects before a test on a sample can be regarded as valid.

1.1. The suitability of the material to be used for the test has to be established. The absence of endotoxins in the water for BET and in the other reagents must be assured and the sensitivity of the amoebocyte lysate must be checked to confirm the sensitivity declared by the manufacturer.

1.2. As the product to be examined may interfere with the test, the sensitivity of the amoebocyte lysate is determined in the presence and in the absence of the product under examination. There must be no significant difference between the 2 sensitivity values.

The test for bacterial endotoxins (*2.6.14*) indicates methods for removing interfering factors; in the case of interference, another test must be carried out after such a method has been applied to check whether the interference has indeed been neutralised or removed.

This annex explains the reasons for the requirements in the test for bacterial endotoxins, then deals with the reading and interpretation of the results.

Substitution of the rabbit pyrogen test required in a pharmacopoeial monograph by an amoebocyte lysate test constitutes the use of an alternative method of analysis and hence requires validation; some guidance on how to proceed is given in section 11.

The reference method for bacterial endotoxins is stated in the monograph on a given product; where no method is stated, method A is the reference method. If a method other than the reference method is to be used, the analyst must demonstrate that the method is appropriate for this product and gives a result consistent with that obtained with the reference method (see also Section 13).

2. METHOD

The addition of endotoxins to amoebocyte lysate may result in turbidity, precipitation or gelation (gel-clot); only the gel-clot method was used in the Pharmacopoeia as an evaluation criterion in the first type of test for bacterial endotoxins. The advantage was the simplicity of basing the decision to pass or fail the product under examination on the absence or presence of a gel-clot, visible with the naked eye. The quantitative methods described as methods C, D, E and F were developed later: they require more instrumentation, but they are easier to automate for the regular testing of large numbers of samples of the same product.

Endotoxins may be adsorbed onto the surface of tubes or pipettes made from certain plastics or types of glass. Interference may appear due to the release of substances from plastic materials. Hence, the materials used should be checked; subsequent batches of tubes or pipettes may have a slightly different composition, and therefore the analyst is advised to repeat such tests on starting with new batches of materials.

The decision to use the test for bacterial endotoxins as a limit test implies first, that a threshold endotoxin concentration must be defined for the product to be tested and second, that the objective of the test is to know whether the endotoxin concentration in the product under examination is below or above this threshold. The quantitative methods C, D, E and F make it possible to determine the endotoxin concentration in the sample under examination, but for compliance with the Pharmacopoeia and in routine quality control the final question is whether or not this concentration exceeds a defined limit.

In setting a threshold concentration of endotoxin for the product to be tested, due attention should be paid to the dose of the product: the threshold should be set so as to ensure that as long as the endotoxin concentration in the product remains below this threshold even the maximal dose administered by the intended route per hour does not contain sufficient endotoxin to cause a toxic reaction.

When the endotoxin concentration in the product exactly equals the threshold value, gelation will occur, as is the case when the endotoxin concentration is much higher, and the product will fail the test, because the all-or-none character of the test makes it impossible to differentiate between a concentration exactly equal to the threshold concentration and one that is higher. It is only when no gelation occurs that the analyst may conclude that the endotoxin concentration is below the threshold concentration.

For products in the solid state, this threshold concentration of endotoxin per mass unit or per International Unit (IU) of product has to be translated into a concentration of endotoxin per millilitre of solution to be tested, as the test can only be carried out on a solution. The case of products that already exist in the liquid state (such as infusion fluids) is discussed below.

Endotoxin limit: the endotoxin limit for active substances administered parenterally, defined on the basis of dose, is equal to, where:

$$\frac{K}{M}$$

K = threshold pyrogenic dose of endotoxin per kilogram of body mass in a single hour period,

M = maximum recommended dose of product per kilogram of body mass in a single hour period.

The endotoxin limit depends on the product and its route of administration and is stated in monographs. Values for K are suggested in Table 2.6.14.-5.

For other routes, the acceptance criterion for bacterial endotoxins is generally determined on the basis of results obtained during the development of the preparation.

Table 2.6.14.-5

Route of administration	*K* (IU of endotoxin per kilogram of body mass per hour)
Intravenous	5.0
Intravanous, for radiopharmaceuticals	2.5
Intrathecal	0.2

Which dilution of the product is to be used in the test to obtain maximal assurance that a negative result means that the endotoxin concentration of the product is less than the endotoxin limit and that a positive result means that the lysate detected an endotoxin concentration equal to or greater than the endotoxin limit? This dilution depends on the endotoxin limit and on the sensitivity of the lysate: it is called the Maximum Valid Dilution (MVD) and its value may be calculated as follows:

$$\frac{\text{endotoxin limit} \times \text{concentration of test solution}}{\lambda}$$

Concentration of test solution:

- in mg/ml if the endotoxin limit is specified by mass (IU/mg),
- in Units/ml if the endotoxin limit is specified by unit of biological activity (IU/Unit),
- in ml/ml if the endotoxin limit is specified by volume (IU/ml).

λ = the labelled lysate sensitivity in the gel-clot technique (IU/ml) or the lowest point used in the standard curve of the turbidimetric or chromogenic techniques.

When the value of the maximum valid dilution is not a whole number, a convenient whole number smaller than the MVD may be used for routine purposes (which means preparing a solution of the product which is less diluted than the MVD indicates). In this case, a negative result indicates that the endotoxin concentration of the product lies below the limit value. However, when the endotoxin concentration of the product in such a test is less than the endotoxin limit but high enough to make the reaction with the lysate result in a clot, the test may be positive under these conditions. Hence, when a test with this 'convenient' dilution factor is

positive, the product should be diluted to the MVD and the test should be repeated. In any case of doubt or dispute the MVD must be used.

This stresses the importance of the confirmation of the sensitivity of the lysate.

Example

A 50 mg/ml solution of phenytoin sodium (intended for intravenous injection) has to be tested. Determine the MVD, given the following variables:

M = maximum human dose = 15 mg per kilogram of body mass per hour,

c = 50 mg/ml,

K = 5 IU of endotoxin per kilogram of body mass per hour,

λ = 0.4 IU of endotoxin per millilitre.

$$\mathrm{MVD} = \frac{5 \times 50}{15} \times \frac{1}{0.4} = 41.67$$

For routine tests on this product, it may be expedient to dilute 1 ml of the solution to be tested to 20 ml (MVD/2 rounded to the next lower whole number). However, if this test result is positive the analyst will have to dilute 1 ml to 41.67 ml and repeat the test. A dilution to 41.67 ml is also necessary when the test is performed to settle a dispute.

3. REFERENCE MATERIAL

Endotoxin standard BRP is intended for use as the reference preparation. It has been assayed against the WHO International Standard for Endotoxin and its potency is expressed in International Units of endotoxin per ampoule. The International Unit of endotoxin is defined as the specific activity of a defined mass of the International Standard.

For routine purposes, another preparation of endotoxin may be used, provided it has been assayed against the International Standard for Endotoxin or the BRP and its potency is expressed in International Units of endotoxin.

NOTE: 1 International Unit (IU) of endotoxin is equal to 1 Endotoxin Unit (E.U.).

4. WATER FOR BET

Testing the absence of endotoxin in this reagent by a technique derived from the rabbit pyrogen test was rejected for practical and theoretical reasons:

4.1. The rabbit test is not sensitive enough to detect endotoxin in water for BET intended for tests on products with a very low endotoxin limit.

4.2. The relatively low precision of the rising temperature response in rabbits would call for many replications in rabbits.

4.3. The terms 'pyrogens' and 'endotoxins' denote groups of entities that do not coincide completely.

The text of the test for bacterial endotoxins indicates that methods other than triple distillation may be used to prepare water for BET. Reverse osmosis has been used with good results; some analysts may prefer to distil the water more than three times. Whatever method is used, the resultant product must be free of detectable endotoxins.

5. pH OF THE MIXTURE

In the test for bacterial endotoxins, optimum gel-clot occurs for a mixture at pH 6.0 to 8.0. However, the addition of the lysate to the sample may result in a lowering of the pH.

6. VALIDATION OF THE LYSATE

It is important to follow the manufacturer's instructions for the preparation of the solutions of the lysate.

The positive end-point dilution factors in the gel-clot methods A and B are converted to logarithms. The reason is that if the frequency distribution of these logarithmic values is plotted, it usually approaches a normal distribution curve much more closely than the frequency distribution of the dilution factors themselves; in fact it is so similar that it is acceptable to use the normal frequency distribution as a mathematical model and to calculate confidence limits with Student's *t*-test.

7. PRELIMINARY TEST FOR INTERFERING FACTORS

Some products cannot be tested directly for the presence of endotoxins because they are not miscible with the reagents, they cannot be adjusted to pH 6.0 to 8.0 or they inhibit or activate gel formation. Therefore a preliminary test is required to check for the presence of interfering factors; when these are found the analyst must demonstrate that the procedure to remove them has been effective.

The object of the preliminary test is to test the null hypothesis that the sensitivity of the lysate in the presence of the product under examination does not differ significantly from the sensitivity of the lysate in the absence of the product. A simple criterion is used in methods A and B: the null hypothesis is accepted when the sensitivity of the lysate in the presence of the product is at least 0.5 times and not more than twice the sensitivity of the lysate by itself.

A classical approach would have been to calculate the means of the log dilution factor for the lysate sensitivity with and without the product and to test the difference between the two means with Student's *t*-test.

The test for interfering factors in gel-clot methods A and B requires the use of a sample of the product in which no endotoxins are detectable. This presents a theoretical problem when an entirely new product has to be tested. Hence, a different approach was designed for quantitative methods C, D, E and F.

8. REMOVAL OF INTERFERING FACTORS

The procedures to remove interfering factors must not increase or decrease (for example, by adsorption) the amount of endotoxin in the product under examination. The correct way of checking this is to apply the procedures to a spiked sample of the product, that is, a sample to which a known amount of endotoxin has been added, and then to measure the recovery of the endotoxin.

Methods C and D. If the nature of the product to be analysed shows interference which cannot be removed by classical methods, it may be possible to carry out the standard curve in the same type of product freed from endotoxins by appropriate treatment or by dilution of the product. The endotoxins test is then carried out by comparison with this standard curve.

Ultrafiltration with cellulose triacetate asymmetric membrane filters has been found to be suitable in most cases. The filters should be properly validated, because under some circumstances cellulose derivatives (β-D-glucans) can cause false positive results.

Polysulphone filters have been found to be unsuitable because false positive results had been obtained by some users.

9. THE PURPOSE OF THE CONTROLS

The purpose of the control made up with water for BET and the reference preparation of endotoxin at twice the concentration of the labelled lysate sensitivity is to verify the activity of the lysate at the time and under the conditions of the test. The purpose of the negative control is to verify the absence of a detectable concentration of endotoxin in water for BET.

The positive control, which contains the product to be examined at the concentration used in the test, is intended to show the absence of inhibiting factors at the time and under the conditions of the test.

10. READING AND INTERPRETATION OF THE RESULTS

Minute amounts of endotoxin in the water for BET, or in any other reagent or material to which the lysate is exposed during the test, may escape detection as long as they do not reach the sensitivity limit of the lysate. However, they may raise the amount of endotoxin in the solution containing the product under examination to just above the sensitivity limit and cause a positive reaction.

The risk of this happening may be reduced by testing the water for BET and the other reagents and materials with the most sensitive lysate available, or at least one that is more sensitive than the one used in the test on the product. Even then, the risk of such a 'false positive result' cannot be ruled out completely. It should be realised, however, that in this respect the test design is 'fail-safe' in contrast to a test design permitting a false negative result, which could lead to the release of an unsatisfactory product, thus endangering the patient's health.

11. REPLACEMENT OF THE RABBIT PYROGEN TEST BY A TEST FOR BACTERIAL ENDOTOXINS

Monographs on pharmaceutical products intended for parenteral use that may contain toxic amounts of bacterial endotoxins require either a test for bacterial endotoxins or a rabbit pyrogen test. As a general policy:

11.1. In any individual monograph, when a test is required, only one test is included, either that for pyrogens or that for bacterial endotoxins.

11.2. In the absence of evidence to the contrary, the test for bacterial endotoxins is preferred over the test for pyrogens, since it is usually considered to provide equal or better protection to the patient.

11.3. Before including a test for bacterial endotoxins in a monograph, evidence is required that one of the tests described in chapter *2.6.14* can be applied satisfactorily to the product in question.

11.4. The necessary information is sought from manufacturers. Companies are invited to provide any validation data that they have concerning the applicability of the test for bacterial endotoxins to the substances and formulations of interest. Such data include details of sample preparation and of any procedures necessary to eliminate interfering factors. In addition, any available parallel data for rabbit pyrogen testing that would contribute to an assurance that the replacement of a rabbit pyrogen test by the test for bacterial endotoxin is appropriate, must be provided.

Additional requirements are defined in the following sections.

12. USE OF A DIFFERENT BACTERIAL ENDOTOXIN TEST FROM THAT PRESCRIBED IN THE MONOGRAPH

When a test for bacterial endotoxins is prescribed in a monograph and none of the six methods (A to F) described in chapter *2.6.14* is specified, then method A, the gel-clot method limit test, has been validated for this product. If one of the other methods (B to F) is specified, this is the one which has been validated for this product.

13. VALIDATION OF ALTERNATIVE METHODS

Replacement of a rabbit pyrogen test by a bacterial endotoxin test, or replacement of a stated or implied method for bacterial endotoxins by another method, is to be regarded as the use of an alternative method in the replacement of a pharmacopoeial test, as described in the General Notices:

> "The test and assays described are the official methods upon which the standards of the Pharmacopoeia are based. With the agreement of the competent authority, alternative methods of analysis may be used for control purposes, provided that the methods used enable an unequivocal decision to be made as to whether compliance with the standards of the monographs would be achieved if the official methods were used. In the event of doubt or dispute, the methods of analysis of the Pharmacopoeia are alone authoritative."

The following procedures are suggested for validating a method for bacterial endotoxins other than the one implied or indicated in the monograph.

13.1. The procedure and the materials and reagents used in the method should be validated as described for the test concerned.

13.2. The presence of interfering factors (and, if needed, the procedure for removing them) should be tested on samples of at least three production batches. It should be borne in mind that methods D and E, using a chromogenic peptide, require reagents that are absent in methods A, B, C and F, and hence compliance of methods A, B, C or F with the requirements for interfering factors cannot be extrapolated to method D or method E without further testing.

14. VALIDATION OF THE TEST FOR NEW PRODUCTS

The procedures described under 13.1 and 13.2 should be applied to all new products intended for parenteral use that have to be tested for the presence of bacterial endotoxins according to the requirements of the Pharmacopoeia.

01/2008:20615

2.6.15. PREKALLIKREIN ACTIVATOR

Prekallikrein activator (PKA) activates prekallikrein to kallikrein and may be assayed by its ability to cleave a chromophore from a synthetic peptide substrate so that the rate of cleavage can be measured spectrophotometrically and the concentration of PKA calculated by comparison with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of the International Standard which consists of freeze-dried prekallikrein activator. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

REAGENTS

Prekallikrein activator in albumin BRP is calibrated in International Units by comparison with the International Standard.

Buffer A. Dissolve 6.055 g of *tris(hydroxymethyl)aminomethane R*, 1.17 g of *sodium chloride R*, 50 mg of *hexadimethrine bromide R* and 0.100 g of *sodium azide R* in *water R*. Adjust to pH 8.0 with *2 M hydrochloric acid R* and dilute to 1000 ml with *water R*.

Buffer B. Dissolve 6.055 g of *tris(hydroxymethyl)aminomethane R* and 8.77 g of *sodium chloride R* in *water R*. Adjust to pH 8.0 with *2 M hydrochloric acid R* and dilute to 1000 ml with *water R*.

PREPARATION OF PREKALLIKREIN SUBSTRATE

To avoid coagulation activation, blood or plasma used for the preparation of prekallikrein must come into contact only with plastics or silicone-treated glass surfaces.

Draw 9 volumes of human blood into 1 volume of anticoagulant solution (ACD, CPD or 38 g/l solution of *sodium citrate R*) to which 1 mg/ml of *hexadimethrine*

bromide R has been added. Centrifuge the mixture at 3600 *g* for 5 min. Separate the plasma and centrifuge again at 6000 *g* for 20 min to sediment platelets. Separate the platelet-poor plasma and dialyse against 10 volumes of buffer A for 20 h. Apply the dialysed plasma to a chromatography column containing *agarose-DEAE for ion exchange chromatography R* which has been equilibrated in buffer A and is equal to twice the volume of the plasma. Elute from the column with buffer A at 20 ml/cm^2/h. Collect the eluate in fractions and record the absorbance at 280 nm (*2.2.25*). Pool the fractions containing the first protein peak so that the volume of the pool is about 1.2 times the volume of the platelet-poor plasma.

Test the substrate pool for absence of kallikrein activity by mixing 1 part with 20 parts of the pre-warmed chromogenic substrate solution to be used in the assay and incubate at 37 °C for 2 min. The substrate is suitable if the increase in absorbance is less than 0.001 per minute. Add to the pooled solution 7 g/l of *sodium chloride R* and filter using a membrane filter (porosity 0.45 µm). Freeze the filtrate in portions and store at – 25 °C; the substrate may be freeze-dried before storage.

Carry out all procedures from the beginning of the chromatography to freezing in portions during a single working day.

METHOD

The assay may be carried out using an automated enzyme analyser or a suitable microtitre plate system allowing kinetic measurements, with appropriate software for calculation of results. Standards, samples and prekallikrein substrate may be diluted as necessary using buffer B.

Incubate diluted standards or samples with prekallikrein substrate for 10 min such that the volume of the undiluted sample does not exceed 1/10 of the total volume of the incubation mixture to avoid errors caused by variation in ionic strength and pH in the incubation mixture. Incubate the mixture or a part thereof with at least an equal volume of a solution of a suitable synthetic chromogenic substrate, known to be specific for kallikrein (for example, *N-benzoyl-L-prolyl-L-phenylalanyl-L-arginine 4-nitroanilide acetate R* or *D-prolyl-L-phenylalanyl-L-arginine-4-nitroanilide-dihydrochloride R*), dissolved in buffer B. Record the rate of change in absorbance per minute for 2-10 min at the wavelength specific for the substrate used. Prepare a blank for each mixture of sample or standard using buffer B instead of prekallikrein substrate.

Depending on the method used, ΔA/min has to be corrected by subtracting the value obtained for the corresponding blank without the prekallikrein substrate. The results may be calculated using a standard curve, a parallel-line or a slope ratio assay or any other suitable statistical method. Plot a calibration curve using the values thus obtained for the reference preparation and the respective concentrations; use the curve to determine the PKA activity of the preparation to be examined.

01/2008:20616

2.6.16. TESTS FOR EXTRANEOUS AGENTS IN VIRAL VACCINES FOR HUMAN USE

In those tests that require prior neutralisation of the virus, use specific antibodies of non-human, non-simian origin; if the virus has been propagated in avian tissues, the antibodies must also be of non-avian origin. To prepare antiserum, use an immunising antigen produced in cell culture from a species different from that used for the production of the vaccine and free from extraneous agents. Where the use of SPF eggs is prescribed, the eggs are obtained from a flock free from specified pathogens (*5.2.2*).

VIRUS SEED LOT

Take samples of the virus seed lot at the time of harvesting and, if they are not tested immediately, keep them at a temperature below – 40 °C.

Adult mice. Inoculate each of at least ten adult mice, each weighing 15 g to 20 g, intracerebrally with 0.03 ml and intraperitoneally with 0.5 ml of the virus seed lot. Observe the mice for at least 21 days. Carry out an autopsy of all mice that die after the first 24 h of the test or that show signs of illness and examine for evidence of viral infection, both by direct macroscopical observation and by subinoculation of appropriate tissue suspensions by the intracerebral and intraperitoneal routes into at least five additional mice which are observed for 21 days. The virus seed lot complies with the test if no mouse shows evidence of infection attributable to the seed lot. The test is not valid unless at least 80 per cent of the original inoculated mice survive the observation period.

Suckling mice. Inoculate each of at least twenty mice, less than 24 h old, intracerebrally with 0.01 ml and intraperitoneally with at least 0.1 ml of the virus seed lot. Observe the mice daily for at least 14 days. Carry out an autopsy of all mice that die after the first 24 h of the test or that show signs of illness and examine for evidence of viral infection, both by direct macroscopical observation and by subinoculation of appropriate tissue suspensions by the intracerebral and intraperitoneal routes into at least five additional suckling mice which are observed daily for 14 days. The virus seed lot passes the test if no mouse shows evidence of infection attributable to the seed lot. The test is not valid unless at least 80 per cent of the original inoculated mice survive the observation period.

Guinea-pigs. Inoculate intraperitoneally into each of at least five guinea pigs, each weighing 350 g to 450 g, 5.0 ml of the virus seed lot. Observe the animals for at least 42 days for signs of disease. Carry out an autopsy of all guinea-pigs that die after the first 24 h of the test, or that show signs of illness and examine macroscopically; examine the tissues both microscopically and culturally for evidence of infection. Euthanise animals that survive the observation period and examine in a similar manner. The virus seed lot passes the test if no guinea-pig shows evidence of infection attributable to the seed lot. The test is not valid unless at least 80 per cent of the guinea-pigs survive the observation period.

VIRUS SEED LOT AND VIRUS HARVESTS

Take samples at the time of harvesting and, if not tested immediately, keep them at a temperature below – 40 °C.

Bacterial and fungal sterility. A 10 ml sample complies with the test for sterility (*2.6.1*).

Mycoplasmas. A 10 ml sample complies with the test for mycoplasmas (*2.6.7*).

Mycobacteria (*2.6.2*). A 5 ml sample is tested for the presence of *Mycobacterium spp.* by culture methods known to be sensitive for the detection of these organisms.

Test in cell culture for other extraneous agents. Neutralised samples equivalent, unless otherwise prescribed, to 500 human doses of vaccine or 50 ml, whichever is the greater, are tested for the presence of extraneous agents by inoculation into continuous simian kidney and human cell cultures. If the virus is grown in human diploid cells, the neutralised virus harvest is also tested on a separate

culture of the diploid cells. If the vaccine virus is grown in a cell system other than simian or human, cells of that species, from a separate batch, are also inoculated. The cells are incubated at 36 ± 1 °C and observed for a period of 14 days. The virus seed lot or harvest passes the tests if none of the cell cultures shows evidence of the presence of any extraneous agents not attributable to accidental contamination. The test is not valid unless at least 80 per cent of the cell cultures remain viable.

Avian viruses (only required for virus propagated in avian tissues). Neutralise a sample equivalent to 100 human doses or 10 ml, whichever is the greater. Using 0.5 ml per egg, inoculate a group of fertilised SPF eggs, 9 to 11 days old, by the allantoic route and a second group, 5 to 7 days old, into the yolk sac. Incubate for 7 days. The virus seed lot or harvest complies with the test if the allantoic and yolk sac fluids show no sign of the presence of any haemagglutinating agent and if all embryos and chorio-allantoic membranes, examined for gross pathology, are normal. The test is not valid unless at least 80 per cent of the inoculated eggs survive for 7 days.

PRODUCTION CELL CULTURE: CONTROL CELLS

Examine the control cells microscopically for freedom from any virus causing cytopathic degeneration throughout the time of incubation of the inoculated production cell cultures or for not less than 14 days beyond the time of inoculation of the production vessels, whichever is the longer. The test is not valid unless at least 80 per cent of the control cell cultures survive to the end of the observation period.

At 14 days or at the time of the last virus harvest, whichever is the longer, carry out the tests described below.

Test for haemadsorbing viruses. Examine not fewer than 25 per cent of the control cultures for the presence of haemadsorbing viruses by the addition of guinea-pig red blood cells. If the guinea-pig red blood cells have been stored, they shall have been stored at 5 ± 3 °C for not more than 7 days. Read half of the cultures after incubation at 5 ± 3 °C for 30 min and the other half after incubation at 20 °C to 25 °C for 30 min. No evidence of haemadsorbing agents is found.

Tests in cell cultures for other extraneous agents. Pool the supernatant fluids from the control cells and examine for the presence of extraneous agents by inoculation of simian kidney and human cell cultures. If the vaccine virus is grown in a cell system other than simian or human, cells of that species, but from a separate batch, are also inoculated. In each cell system, at least 5 ml is tested. Incubate the inoculated cultures at a temperature of 36 ± 1 °C and observe for a period of 14 days. No evidence of extraneous agents is found.

If the production cell culture is maintained at a temperature different from 36 ± 1 °C, a supplementary test for extraneous agents is carried out at the production temperature using the same type of cells as used for growth of the virus.

Avian leucosis viruses (required only if the virus is propagated in avian tissues). Carry out a test for avian leucosis viruses using 5 ml of the supernatant fluid from the control cells.

CONTROL EGGS

Haemagglutinating agents. Examine 0.25 ml of the allantoic fluid from each egg for haemagglutinating agents by mixing directly with chicken red blood cells and after a passage in SPF eggs carried out as follows: inoculate a 5 ml sample of the pooled amniotic fluids from the control eggs in 0.5 ml volumes into the allantoic cavity and into the amniotic cavity of SPF eggs. The control eggs comply with the test if no evidence of the presence of haemagglutinating agents is found in either test.

Avian leucosis viruses. Use a 10 ml sample of the pooled amniotic fluids from the control eggs. Carry out amplification by five passages in leucosis-free chick-embryo cell cultures; carry out a test for avian leucosis using cells from the fifth passage. The control eggs comply with the test if no evidence of the presence of avian leucosis viruses is found.

Other extraneous agents. Inoculate 5 ml samples of the pooled amniotic fluids from the control eggs into human and simian cell cultures. Observe the cell cultures for 14 days. The control eggs comply with the test if no evidence of the presence of extraneous agents is found. The test is not valid unless 80 per cent of the inoculated cultures survive to the end of the observation period.

01/2008:20617

2.6.17. TEST FOR ANTICOMPLEMENTARY ACTIVITY OF IMMUNOGLOBULIN

For the measurement of anticomplementary activity (ACA) of immunoglobulin, a defined amount of test material (10 mg of immunoglobulin) is incubated with a defined amount of guinea-pig complement (20 CH_{50}) and the remaining complement is titrated; the anticomplementary activity is expressed as the percentage consumption of complement relative to the complement control considered as 100 per cent.

The haemolytic unit of complement activity (CH_{50}) is the amount of complement that, in the given reaction conditions, will produce the lysis of 2.5×10^8 out of a total of 5×10^8 optimally sensitised red blood cells.

Magnesium and calcium stock solution. Dissolve 1.103 g of *calcium chloride R* and 5.083 g of *magnesium chloride R* in *water R* and dilute to 25 ml with the same solvent.

Barbital buffer stock solution. Dissolve 207.5 g of *sodium chloride R* and 25.48 g of *barbital sodium R* in 4000 ml of *water R* and adjust to pH 7.3 using *1 M hydrochloric acid*. Add 12.5 ml of magnesium and calcium stock solution and dilute to 5000 ml with *water R*. Filter through a membrane filter (pore size 0.22 µm). Store at 4 °C in glass containers.

Gelatin solution. Dissolve 12.5 g of *gelatin R* in about 800 ml of *water R* and heat to boiling in a water-bath. Cool to 20 °C and dilute to 10 litres with *water R*. Filter through a membrane filter (pore size: 0.22 µm). Store at 4 °C. Use clear solutions only.

Citrate solution. Dissolve 8.0 g of *sodium citrate R*, 4.2 g of *sodium chloride R* and 20.5 g of *glucose R* in 750 ml of *water R*. Adjust to pH 6.1 using a 100 g/l solution of *citric acid R* and dilute to 1000 ml with *water R*.

Gelatin barbital buffer solution. Add 4 volumes of gelatin solution to 1 volume of barbital buffer stock solution and mix. Adjust to pH 7.3, if necessary, using *1 M sodium hydroxide* or *1 M hydrochloric acid*. Maintain at 4 °C. Prepare fresh solutions daily.

Stabilised sheep blood. Collect one volume of sheep blood into one volume of citrate solution and mix. Store at 4 °C for not less than 7 days and not more than 28 days. (Stabilised sheep blood and sheep red blood cells are available from a number of commercial sources.)

Haemolysin. Antiserum against sheep red blood cells prepared in rabbits. (Such antisera are available from a number of commercial sources.)

Guinea-pig complement. Prepare a pool of serum from the blood of not fewer than ten guinea-pigs. Separate the serum from the clotted blood by centrifugation at about 4 °C. Store the serum in small amounts below – 70 °C.

METHOD

Preparation of standardised 5 per cent sheep red blood cell suspension. Separate sheep red blood cells by centrifuging an appropriate volume of stabilised sheep blood and wash the cells at least three times with gelatin barbital buffer solution and prepare as a 5 per cent *V/V* suspension in the same solution. Measure the cell density of the suspension as follows: add 0.2 ml to 2.8 ml of *water R* and centrifuge the lysed solution for 5 min at 1000 *g*; the cell density is suitable if the absorbance (*2.2.25*) of the supernatant liquid at 541 nm is 0.62 ± 0.01. Correct the cell density by adding gelatin barbital buffer solution according to the formula:

$$V_f = \frac{V_i \times A}{0.62}$$

V_f = final adjusted volume,

V_i = the initial volume,

A = absorbance of the original suspension at 541 nm.

The adjusted suspension contains about 1×10^9 cells/ml.

Haemolysin titration

Prepare haemolysin dilutions as shown in Table 2.6.17.-1.

Table 2.6.17.-1

Required dilution of haemolysin	Prepared using		
	Gelatin barbital buffer solution		Haemolysin
	Volume (millilitres)	Dilution (1: ...)	Volume (millilitres)
7.5	0.65	undiluted	0.1
10	0.90	undiluted	0.1
75	1.80	7.5	0.2
100	1.80	10	0.2
150	1.00	75	1.0
200	1.00	100	1.0
300	1.00	150	1.0
400	1.00	200	1.0
600	1.00	300	1.0
800	1.00	400	1.0
1200	1.00	600	1.0
1600	1.00	800	1.0
2400	1.00	1200	1.0
3200*	1.00	1600	1.0
4800*	1.00	2400	1.0

* discard 1.0 ml of the mixture.

Add 1.0 ml of 5 per cent sheep red blood cell suspension to each tube of the haemolysin dilution series, starting at the 1:75 dilution, and mix. Incubate at 37 °C for 30 min.

Transfer 0.2 ml of each of these incubated mixtures to new tubes and add 1.10 ml of gelatin barbital buffer solution and 0.2 ml of diluted guinea-pig complement (for example, 1:150). Perform this in duplicate.

As the unhaemolysed cell control, prepare three tubes with 1.4 ml of gelatin barbital buffer solution and 0.1 ml of 5 per cent sheep red blood cell suspension.

As the fully haemolysed control, prepare three tubes with 1.4 ml of *water R* and 0.1 ml of 5 per cent sheep red cell suspension.

Incubate all tubes at 37 °C for 60 min and centrifuge at 1000 *g* for 5 min. Measure the absorbance (*2.2.25*) of the supernatants at 541 nm and calculate the percentage degree of haemolysis in each tube using the expression:

$$\frac{A_a - A_1}{A_b - A_1} \times 100$$

A_a = absorbance of tubes with haemolysin dilution,

A_b = mean absorbance of the three tubes with full haemolysis,

A_1 = mean absorbance of the three tubes with no haemolysis.

Plot the percentage degree of haemolysis as the ordinate against the corresponding reciprocal value of the haemolysin dilution as the abscissa on linear graph paper. Determine the optimal dilution of the haemolysin from the graph by inspection. Select a dilution such that further increase in the amount of haemolysin does not cause appreciable change in the degree of haemolysis. This dilution is defined as one minimal haemolytic unit (1 MHU) in 1.0 ml. The optimal haemolytic haemolysin dilution for preparation of sensitised sheep red blood cells contains 2 MHU/ml.

The haemolysin titration is not valid unless the maximum degree of haemolysis is 50 per cent to 70 per cent. If the maximum degree of haemolysis is not in this range, repeat the titration with more or less diluted complement solution.

Preparation of optimised sensitised sheep red blood cells (haemolytic system)

Prepare an appropriate volume of diluted haemolysin containing 2 MHU/ml and an equal volume of standardised 5 per cent sheep red blood cell suspension. Add the haemolysin dilution to the standardised cell suspension and mix. Incubate at 37 °C for 15 min, store at 2 °C to 8 °C and use within 6 h.

Titration of complement

Prepare an appropriate dilution of complement (for example, 1:250) with gelatin barbital buffer solution and perform the titration in duplicate as shown in Table 2.6.17.-2.

Add 0.2 ml of sensitised sheep red blood cells to each tube, mix well and incubate at 37 °C for 60 min. Cool the tubes in an ice-bath and centrifuge at 1000 *g* for 5 min. Measure the absorbance of the supernatant liquid at 541 nm and calculate the degree of haemolysis (*Y*) using the expression:

$$\frac{A_c - A_1}{A_b - A_1}$$

A_c = absorbance of tubes 1 to 12,

A_b = mean absorbance of tubes with 100 per cent haemolysis,

A_1 = mean absorbance of cell controls with 0 per cent haemolysis.

Plot $Y/(1-Y)$ as the abscissa against the amount of diluted complement in millilitres as the ordinate on log–log graph paper. Fit the best line to the points and determine the ordinate for the 50 per cent haemolytic complement dose where $Y/(1-Y) = 1.0$. Calculate the activity in haemolytic units (CH_{50}/ml) from the expression:

$$\frac{C_d}{C_a \times 5}$$

C_d = reciprocal value of the complement dilution,

C_a = volume of diluted complement in millilitres resulting in 50 per cent haemolysis,

5 = scaling factor to take account of the number of red blood cells.

The test is not valid unless the plot is a straight line between 15 per cent and 85 per cent haemolysis and the slope is 0.15 to 0.40, and preferably 0.18 to 0.30.

Table 2.6.17.-2

Tube Number	Volume of diluted complement in millilitres (for example 1:250)	Volume of gelatin barbital buffer solution in millilitres
1	0.1	1.2
2	0.2	1.1
3	0.3	1.0
4	0.4	0.9
5	0.5	0.8
6	0.6	0.7
7	0.7	0.6
8	0.8	0.5
9	0.9	0.4
10	1.0	0.3
11	1.1	0.2
12	1.2	0.1
Three tubes as cell control at 0 per cent haemolysis	–	1.3
Three tubes at 100 per cent haemolysis	–	1.3 ml of water

Test for anticomplementary activity

Prepare a complement dilution having 100 CH_{50}/ml by diluting titrated guinea-pig complement with gelatin barbital buffer solution. If necessary, adjust the immunoglobulin to be examined to pH 7. Prepare incubation mixtures as follows for an immunoglobulin containing 50 mg/ml:

Table 2.6.17.-3

	Immunoglobulin to be examined	Complement control (in duplicate)
Immunoglobulin (50 mg/ml)	0.2 ml	–
Gelatin barbital buffer	0.6 ml	0.8 ml
Complement	0.2 ml	0.2 ml

Carry out the test on the immunoglobulin to be examined and prepare ACA negative and positive controls using *human immunoglobulin BRP*, as indicated in the leaflet accompanying the reference preparation. Higher or lower volumes of sample and of gelatin barbital buffer solution are added if the immunoglobulin concentration varies from 50 mg/ml; for example, 0.47 ml of gelatin barbital buffer solution is added to 0.33 ml of immunoglobulin containing 30 mg/ml to give 0.8 ml. Close the tubes and incubate at 37 °C for 60 min. Add 0.2 ml of each incubation mixture to 9.8 ml of gelatin barbital buffer solution to dilute the complement. Perform complement titrations as described above on each tube to determine the remaining complement activity (Table 2.6.17.-2). Calculate the anticomplementary activity of the preparation to be examined relative to the complement control considered as 100 per cent, from the expression:

$$\frac{a - b}{a} \times 100$$

a = mean complement activity (CH_{50}/ml) of complement control,

b = complement activity (CH_{50}/ml) of tested sample.

The test is not valid unless:

- the anticomplementary activities found for ACA negative control and ACA positive control are within the limits stated in the leaflet accompanying the reference preparation,
- the complement activity of the complement control (a) is in the range 80 to 120 CH_{50}/ml.

01/2008:20618

2.6.18. TEST FOR NEUROVIRULENCE OF LIVE VIRUS VACCINES

For each test, use not fewer than ten monkeys that are seronegative for the virus to be tested. For each monkey, inject not more than 0.5 ml of the material to be examined into the thalamic region of each hemisphere, unless otherwise prescribed. The total amount of virus inoculated in each monkey must be not less than the amount contained in the recommended single human dose of the vaccine. As a check against the introduction of wild neurovirulent virus, keep a group of not fewer than four control monkeys as cage-mates or in the immediate vicinity of the inoculated monkeys. Observe the inoculated monkeys for 17 to 21 days for symptoms of paralysis and other evidence of neurological involvement; observe the control monkeys for the same period plus 10 days. Animals that die within 48 h of injection are considered to have died from non-specific causes and may be replaced. The test is not valid if: more than 20 per cent of the inoculated monkeys die from nonspecific causes; serum samples taken from the control monkeys at the time of inoculation of the test animals and 10 days after the latter are euthanised show evidence of infection by wild virus of the type to be tested or by measles virus. At the end of the observation period, carry out autopsy and histopathological examinations of appropriate areas of the brain for evidence of central nervous system involvement. The material complies with the test if there is no unexpected clinical or histopathological evidence of involvement of the central nervous system attributable to the inoculated virus.

01/2008:20619

2.6.19. TEST FOR NEUROVIRULENCE OF POLIOMYELITIS VACCINE (ORAL)

Monkeys used in the neurovirulence test comply with the requirements given in the monograph on *Poliomyelitis vaccine oral (0215)* and weigh not less than 1.5 kg. The pathogenicity for *Macaca* or *Cercopithecus monkeys* is tested in comparison with that of a reference virus preparation for neurovirulence testing by inoculation into the lumbar region of the central nervous system after sedation with a suitable substance, for example, ketamine hydrochloride. A sample of serum taken before the injection shall be shown not to contain neutralising antibody at a dilution of 1:4 when tested against not more than 1000 $CCID_{50}$ of each of the three types of poliovirus.

Number of monkeys. The vaccine and the appropriate homotypic reference virus are tested concurrently in the same group of monkeys. Equal numbers of animals are inoculated with the vaccine to be examined and the reference preparation. The animals are allocated randomly to treatment groups and cages and their identity is coded so that the treatment received by each animal is concealed from the observers and the evaluators of the sections. The number of monkeys inoculated is such that in the evaluation of both the vaccine and the reference preparation not fewer than eleven positive monkeys are included for type 1 and type 2 virus and not fewer than eighteen positive monkeys for type 3 virus (positive monkeys are those that show specific neuronal lesions of poliovirus in the central nervous system). More than one batch of vaccine may be tested with the same homotypic reference. Monkeys from the same quarantine group are used wherever possible, otherwise monkeys from two groups are used and equal numbers from each group are treated with the vaccine and the reference preparation. If the test is carried out on two working days, an equal number of monkeys from each group are inoculated on each day with the vaccine and the homotypic reference preparation.

Virus content. The virus contents of the vaccine and the homotypic reference preparation are adjusted so as to be as near as possible equal and between $10^{5.5}$ and $10^{6.5}$ $CCID_{50}$/0.1 ml.

Observation. All monkeys are observed for 17 to 22 days for signs of poliomyelitis or other virus infection. Monkeys that survive the first 24 h but die before the 11th day after inoculation are autopsied to determine whether poliomyelitis was the cause of death. Animals that die from causes other than poliomyelitis are excluded from the evaluation. Animals that become moribund or are severely paralysed are euthanised and autopsied. All animals that survive until the end of the observation period are autopsied. The test is not valid if more than 20 per cent of the animals show intercurrent infection during the observation period.

Number of sections examined. The lumbar cord, the cervical cord, the lower and upper medulla oblongata, the midbrain, the thalamus and the motor cortex of each monkey, as a minimum, are subjected to histological examination. Sections are cut with a thickness of 15 µm and stained with gallocyanin. The minimum number of sections examined is as follows:

(a) 12 sections representative of the whole of the lumbar enlargement,

(b) 10 sections representative of the whole of the cervical enlargement,

(c) 2 sections from the medulla oblongata,

(d) 1 section from the pons and cerebellum,

(e) 1 section from the midbrain,

(f) 1 section from the left and the right of the thalamus,

(g) 1 section from the left and the right motor cerebral cortex.

Scoring of virus activity. For the evaluation of virus activity in the hemisections of the spinal cord and brain-stem, a score system for the severity of lesions is used, differentiating cellular infiltration and destruction of neurons as follows:

1. Cellular infiltration only (the monkey is not counted as positive),

2. Cellular infiltration with minimal neuronal damage,

3. Cellular infiltration with extensive neuronal damage,

4. Massive neuronal damage with or without cellular infiltration.

The scores are recorded on a standard form(1). A monkey with neuronal lesions in the sections but that shows no needle tract is counted as positive. A monkey showing a needle tract in the sections, but no neuronal lesions is not regarded as positive. A section that shows damage from trauma but no specific virus lesions is not included in the score.

Severity scores are based on hemisection readings of the lumbar (L), cervical (C) and brain (B) histological sections. The lesion score (LS) for each positive monkey is calculated as follows:

$$LS = \frac{\left[\begin{matrix}\text{Sum of}\\ \text{L score}\\ \text{Number of}\\ \text{hemisections}\end{matrix}\right] + \left[\begin{matrix}\text{Sum of}\\ \text{C score}\\ \text{Number of}\\ \text{hemisections}\end{matrix}\right] + \left[\begin{matrix}\text{Sum of}\\ \text{B score}\\ \text{Number of}\\ \text{hemisections}\end{matrix}\right]}{3}$$

A mean lesion score is calculated for each group of positive monkeys.

Evaluation. The comparison of the virus activity in the vaccine and the reference preparation is based on the activity in the lumbar enlargement of the cord and the degree of spread of activity from this region to the cervical enlargement and the brain. Acceptance or rejection is based on the total score of all the test animals. Individual animals showing evidence of unusually high activity, either in the lumbar region or as the result of spread from this region, are also taken into consideration in the final evaluation. The monovalent bulk passes the test if the required number of animals is positive and if none of the clinical and histopathological examinations shows a significant difference in pathogenicity between the vaccine virus and the reference material. Criteria for acceptance are given below.

Criteria. A suitable number of neurovirulence qualifying tests (for example, four tests) is carried out on each reference vaccine (types 1, 2 and 3) to provide data on the activity of such vaccines that will serve as the basis of the criteria for vaccines to be tested. The overall mean lesion score (M) for the replicate tests on each reference virus is calculated together with the pooled estimate of the within-test variance (s^2) and the within-test deviation (s).

Validity criteria for the results of a test on a reference preparation are established on the basis of the cumulative data from the qualifying tests. No generally applicable criteria can be given; for laboratories with limited experience, the following empirical method for setting acceptable limits for the mean lesion score for the reference preparation (X_{ref}) may be helpful (see Table 2.6.19.-1):

Table 2.6.19.-1

	Lower limit	Upper limit
Types 1 and 2	$M - s$	$M + s$
Type 3	$M - s/2$	$M + s$

If the mean lesion score for the vaccine to be tested is X_{test} and C_1, C_2 and C_3 are constants determined as described below, then:

(1) A suitable form is shown in the Requirements for Poliomyelitis Vaccine (Oral) (Requirements for Biological Substances No. 7, World Health Organization).

the vaccine is not acceptable if:

$$X_{\text{test}} - X_{\text{ref}} > C_1$$

the vaccine may be retested once if:

$$C_1 < X_{\text{test}} - X_{\text{ref}} < C_2$$

If the vaccine is retested, the means of the lesion scores for the vaccine to be tested and the reference vaccine are recalculated. The vaccine is not acceptable if:

$$\frac{X_{(\text{test } 1+\text{test } 2)} - X_{(\text{ref } 1+\text{ref } 2)}}{2} > C_3$$

The constants C_1, C_2 and C_3 are calculated from the expressions:

$$C_1 = 2.3\sqrt{\frac{2s^2}{N_1}}$$

$$C_2 = 2.6\sqrt{\frac{2s^2}{N_1}}$$

$$C_3 = 1.6\sqrt{\frac{2s^2}{N_1}}$$

N_1 = number of positive monkeys per vaccine test,

N_2 = number of positive monkeys in the two tests,

2.3 = normal deviate at the 1 per cent level,

2.6 = normal deviate at the 0.5 per cent level,

1.6 = normal deviate at the 5 per cent level.

A neurovirulence test in which the mean lesion score for the reference (X_{ref}) is not compatible with previous experience is not used for assessing a test vaccine. If the test is valid, the mean lesion score for the vaccine to be tested (X_{test}) is calculated and compared with that of the homotypic reference vaccine.

01/2008:20620

2.6.20. ANTI-A AND ANTI-B HAEMAGGLUTININS (INDIRECT METHOD)

Prepare in duplicate serial dilutions of the preparation to be examined in a 9 g/l solution of *sodium chloride R*. To each dilution of one series add an equal volume of a 5 per cent *V/V* suspension of group A_1 red blood cells previously washed three times with the sodium chloride solution. To each dilution of the other series add an equal volume of a 5 per cent *V/V* suspension of group B red blood cells previously washed three times with the sodium chloride solution. Incubate the suspensions at 37 °C for 30 min then wash the cells three times with the sodium chloride solution. Leave the cells in contact with a polyvalent anti-human globulin reagent for 30 min. Without centrifuging, examine each suspension for agglutination under a microscope.

01/2008:20621

2.6.21. NUCLEIC ACID AMPLIFICATION TECHNIQUES

1. INTRODUCTION

Nucleic acid amplification techniques are based on 2 different approaches:

1. amplification of a target nucleic acid sequence using, for example, polymerase chain reaction (PCR), ligase chain reaction (LCR), or isothermal ribonucleic acid (RNA) amplification,
2. amplification of a hybridisation signal using, for example, for deoxyribonucleic acid (DNA), the branched DNA (bDNA) method. In this case signal amplification is achieved without subjecting the nucleic acid to repetitive cycles of amplification.

In this general chapter, the PCR method is described as the reference technique. Alternative methods may be used, if they comply with the quality requirements described below.

2. SCOPE

This section establishes the requirements for sample preparation, *in vitro* amplification of DNA sequences and detection of the specific PCR product. With the aid of PCR, defined DNA sequences can be detected. RNA sequences can also be detected following reverse transcription of the RNA to complementary DNA (cDNA) and subsequent amplification.

3. PRINCIPLE OF THE METHOD

PCR is a procedure that allows specific *in vitro* amplification of segments of DNA or of RNA after reverse transcription into cDNA.

Following denaturation of double-stranded DNA into single-stranded DNA, 2 synthetic oligonucleotide primers of opposite polarity, anneal to their respective complementary sequences in the DNA to be amplified. The short double-stranded regions which form as a result of specific base pairing between the primers and the complementary DNA sequence, border the DNA segment to be amplified and serve as starting positions for *in vitro* DNA synthesis by means of a heat-stable DNA polymerase.

Amplification of the DNA occurs in cycles consisting of:

- heat denaturation of the nucleic acid (target sequence) into 2 single strands;
- specific annealing of the primers to the target sequence under suitable reaction conditions;
- extension of the primers, which are bound to both single strands, by DNA polymerase at a suitable temperature (DNA synthesis).

Repeated cycles of heat denaturation, primer annealing and DNA synthesis results in an exponential amplification of the DNA segment limited by the primers.

The specific PCR product known as an amplicon can be detected by a variety of methods of appropriate specificity and sensitivity.

Multiplex PCR assays use several primer pairs designed for simultaneous amplification of different targets in one reaction.

4. TEST MATERIAL

Because of the high sensitivity of PCR, the samples must be protected against external contamination with target sequences. Sampling, storage and transport of the test material are performed under conditions that minimise degradation of the target sequence. In the case of RNA target sequences, special precautions are necessary since RNA is

highly sensitive to degradation by ribonucleases. Care must be taken since some added reagents, such as anticoagulants or preservatives, may interfere with the test procedure.

5. TEST METHOD

5.1. Prevention of contamination

The risk of contamination requires a strict segregation of the areas depending on the material handled and the technology used. Points to consider include movement of personnel, gowning, material flow and air supply and decontamination procedures.

The system should be sub-divided into compartments such as:

- master-mix area (area where exclusively template-free material is handled, e.g. primers, buffers, etc.),
- pre-PCR (area where reagents, samples and controls are handled),
- PCR amplification (amplified material is handled in a closed system),
- post-PCR detection (the only area where the amplified material is handled in an open system).

5.2. Sample preparation

When preparing samples, the target sequence to be amplified needs to be efficiently extracted or liberated from the test material in a reproducible manner and in such a way that amplification under the selected reaction conditions is possible. A variety of physico-chemical extraction procedures and/or enrichment procedures may be employed.

Additives present in test material may interfere with PCR. The procedures described under 7.3.2. must be used as a control for the presence of inhibitors originating from the test material.

In the case of RNA-templates, care must be taken to avoid ribonuclease activity.

5.3. Amplification

PCR amplification of the target sequence is conducted under defined cycling conditions (temperature profile for denaturation of double-stranded DNA, annealing and extension of primers; incubation times at selected temperatures; ramp rates). These depend on various parameters such as:

- the length and base composition of primer and target sequences;
- the type of DNA polymerase, buffer composition and reaction volume used for the amplification;
- the type of thermocycler used and the thermal conductivity rate between the apparatus, reaction tube and reaction fluid.

5.4. Detection

The amplicon generated by PCR may be identified by size, sequence, chemical modification or a combination of these parameters. Detection and characterisation by size may be achieved by gel electrophoresis (using agarose or polyacrylamide slab gels or capillary electrophoresis) or column chromatography (for example, liquid chromatography). Detection and characterisation by sequence composition may be achieved by the specific hybridisation of probes having a sequence complementary to the target sequence or by cleavage of the amplified material reflecting target-specific restriction-enzyme sites. Detection and characterisation by chemical modification may be achieved, for example, by incorporation of a fluorophore into the amplicons and subsequent detection of fluorescence following excitation.

Detection of amplicons may also be achieved by using probes labelled to permit a subsequent radioisotopic or immuno-enzyme-coupled detection.

6. EVALUATION AND INTERPRETATION OF RESULTS

A valid result is obtained within a test only if the positive control(s) is unambiguously positive and the negative control(s) is unambiguously negative. Due to the very high sensitivity of the PCR method and the inherent risk of contamination, it is necessary to confirm positive results by repeating the complete test procedure in duplicate, where possible on a new aliquot of the sample. The sample is considered positive if at least one of the repeat tests gives a positive result. As soon as a measurable target threshold is defined, a quantitative test system is required.

7. QUALITY ASSURANCE

7.1. Validation of the PCR assay system

The validation programme must include validation of instrumentation and the PCR method employed. Reference should be made to the *ICH guidelines* (topic Q2B) Validation of Analytical Method: Methodology.

Appropriate official working reference preparations or in-house reference preparations calibrated against International Standards for the target sequences for which the test system will be used are indispensable for validation of a PCR test.

7.1.1. Determination of the positive cut-off point

During validation of qualitative tests, the positive cut-off point must be determined. The positive cut-off point is defined as the minimum number of target sequences per volume sample which can be detected in 95 per cent of test runs. The positive cut-off point depends on interrelated factors such as the volume of the sample extracted and the efficacy of the extraction methodology, the transcription of the target RNA into cDNA, the amplification process and the detection.

To define the detection limit of the assay system, reference must be made to the positive cut-off point for each target sequence and the test performance above and below the positive cut-off point.

7.1.2. Quantitative assay systems

For a quantitative assay, the following parameters are determined during validation: accuracy, precision, specificity, quantitation limit, linearity, range and robustness.

7.2. Quality control of reagents

All reagents crucial for the methodology used have to be controlled prior to use in routine applications. Their acceptance/withdrawal is based on pre-defined quality criteria.

Primers are a crucial component of the PCR assay and as such their design, purity and the validation of their use in a PCR assay require careful attention. Primers may be modified (for example, by conjugation with a fluorophore or antigen) in order to permit a specific method of detection of the amplicon, provided such modifications do not inhibit accurate and efficient amplification of the target sequence.

7.3. Run controls

7.3.1. External controls

In order to minimise the risk of contamination and to ensure adequate sensitivity, the following external controls are included in each PCR assay:

- positive control: this contains a defined number of target-sequence copies, the number being close to the positive cut-off value, and determined individually for

each assay system and indicated as a multiple of the positive cut-off value of the assay system;

– negative control: a sample of a suitable matrix already proven to be free of the target sequences.

7.3.2. Internal control

Internal controls are defined nucleic acid sequences containing, unless otherwise prescribed, the primer binding sites. Internal controls must be amplified with defined efficacy, and the amplicons must be clearly discernible. Internal controls must be of the same type of nucleic acid (DNA/RNA) as the material to be tested. The internal control is preferably added to the test material before isolating the nucleic acid and therefore acts as an overall control (extraction, reverse transcription, amplification, detection).

7.3.3. Threshold control

The threshold control for quantitative assays is a test sample with the analyte at a concentration which is defined as the threshold not to be exceeded. It contains the analyte suitably calibrated in IU and is analysed in parallel in each run of a quantitative assay.

7.4. External quality assessment

Participation in external quality assessment programmes is an important PCR quality assurance procedure for each laboratory and each operator.

The following section is published for information.

Validation of nucleic acid amplification techniques (NAT) for the detection of hepatitis C virus (HCV) RNA in plasma pools: guidelines

1. SCOPE

The majority of nucleic acid amplification analytical procedures are qualitative (quantal) tests for the presence of nucleic acid with some quantitative tests (either in-house or commercial) being available. For the detection of HCV RNA contamination of plasma pools, qualitative tests are adequate and may be considered to be a limit test for the control of impurities as described in the *Pharmeuropa* Technical Guide for the elaboration of monographs, December 1999, Chapter III "Validation of analytical procedures". These guidelines describe methods to validate only qualitative nucleic acid amplification analytical procedures for assessing HCV RNA contamination of plasma pools. Therefore, the 2 characteristics regarded as the most important for validation of the analytical procedure are the specificity and the detection limit. In addition, the robustness of the analytical procedure should be evaluated.

However, this document may also be used as a basis for the validation of nucleic acid amplification in general.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part of or the complete analytical procedure, documented validation points already covered by the kit manufacturer can substitute for the validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. detection limit, robustness, cross contamination).

2. SPECIFICITY

Specificity is the ability to unequivocally assess nucleic acid in the presence of components which may be expected to be present.

The specificity of nucleic acid amplification analytical procedures is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and detection steps).

When designing primers and probes, the specificity of the primers and probes to detect only HCV RNA should be investigated by comparing the chosen sequences with sequences in published data banks. For HCV, primers (and probes) will normally be chosen from areas of the 5' non-coding region of the HCV genome which are highly conserved for all genotypes.

The amplified product should be unequivocally identified by using one of a number of methods such as amplification with nested primers, restriction enzyme analysis, sequencing or hybridisation with a specific probe.

In order to validate the specificity of the analytical procedure, at least 100 HCV RNA-negative plasma pools should be tested and shown to be non-reactive. Suitable samples of non-reactive pools are available from the European Directorate for the Quality of Medicines.

The ability of the analytical procedure to detect all HCV genotypes will again depend on the choice of primers, probes and method parameters. This ability should be demonstrated using characterised reference panels. However, in view of the difficulty in obtaining samples of some genotypes (e.g. genotype 6), the most prevalent genotypes (e.g. genotype 1 and 3 in Europe) should be detected at a suitable level.

3. DETECTION LIMIT

The detection limit of an individual analytical procedure is the lowest amount of nucleic acid in a sample which can be detected but not necessarily quantitated as an exact value.

The nucleic acid amplification analytical procedure used for the detection of HCV RNA in plasma pools usually yields qualitative results. The number of possible results is limited to two, either positive or negative. Although the determination of the detection limit is recommended, for practical purposes, a positive cut-off point should be determined for the nucleic acid amplification analytical procedure. The positive cut-off point (as defined in the General Chapter (*2.6.21*)) is the minimum number of target sequences per volume sample which can be detected in 95 per cent of test runs. This positive cut-off point is influenced by the distribution of viral genomes in the individual samples being tested and by factors such as enzyme efficiency and can result in different 95 per cent cut-off values for individual analytical test runs.

In order to determine the positive cut-off point, a dilution series of a working reagent or of the *hepatitis C virus BRP*, which has been calibrated against the WHO HCV International Standard 96/790, should be tested on different days to examine variation between test runs. At least 3 independent dilution series should be tested with a sufficient number of replicates at each dilution to give a total number of 24 test results for each dilution to enable a statistical analysis of the results.

For example, a laboratory could test 3 dilution series on different days with 8 replicates for each dilution, 4 dilution series on different days with 6 replicates for each dilution, or 6 dilution series on different days with 4 replicates for each dilution. In order to keep the number of dilutions at a manageable level, a preliminary test (using, for example, log dilutions of the plasma pool sample) should be done in order to obtain a preliminary value for the positive cut-off point (i.e. the highest dilution giving a positive signal). The range of dilutions can then be chosen around the predetermined preliminary cut-off point (using, for example, a dilution

factor of 0.5 log or less and a negative plasma pool for the dilution matrix). The concentration of HCV RNA which can be detected in 95 per cent of test runs can then be calculated using an appropriate statistical evaluation.

These results may also serve to demonstrate the intra-assay variation and the day-to-day variation of the analytical procedure.

4. ROBUSTNESS

The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters and provides an indication of its reliability during normal usage.

The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. However, the robustness of the method can be demonstrated during its development when small variations in the concentrations of reagents (e.g. $MgCl_2$, primers or dNTP) are tested. To demonstrate robustness, at least 20 HCV RNA negative plasma pools (selected at random) spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value should be tested and found positive.

Problems with robustness may also arise with methods which use an initial ultracentrifugation step prior to extraction of the viral RNA. Therefore, to test the robustness of such methods, at least 20 plasma pools containing varying levels of HCV RNA, but lacking HCV specific antibodies, should be tested and found positive.

Cross contamination prevention should be demonstrated by the accurate detection of a panel of at least 20 samples consisting of alternate samples of negative plasma pools and negative plasma pools spiked with high concentrations of HCV (at least 10^2 times the 95 per cent cut-off value or at least 10^4 IU/ml).

5. QUALITY ASSURANCE

For biological tests such as NAT, specific problems may arise which may influence both the validation and interpretation of results. The test procedures must be described precisely in the form of standard operating procedures (SOPs). These should cover:

- the mode of sampling (type of container, etc.),
- the preparation of mini-pools (where appropriate),
- the conditions of storage before analysis,
- the exact description of the test conditions, including precautions taken to prevent cross contamination or destruction of the viral RNA, reagents and reference preparations used,
- the exact description of the apparatus used,
- the detailed formulae for calculation of results, including statistical evaluation.

The use of a suitable run control (for example, an appropriate dilution of *hepatitis C virus BRP* or plasma spiked with an HCV sample calibrated against the WHO HCV International Standard 96/790) can be considered a satisfactory system suitability check and ensures that the reliability of the analytical procedure is maintained whenever used.

Technical qualification: an appropriate installation and operation qualification programme should be implemented for each critical piece of the equipment used. Confirmation of analytical procedure performance after change of critical equipment (e.g. thermocyclers) should be documented by conducting a parallel test on 8 replicate samples of a plasma pool spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value. All results should be positive.

Operator qualification: an appropriate qualification programme should be implemented for each operator involved in the testing. To confirm successful training each operator should test at least 8 replicate samples of a plasma pool spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value. This test (8 replicate samples) should be repeated twice on two separate days, i.e. a total of 24 tests performed on three different days. All results should be positive.

01/2008:20622

2.6.22. ACTIVATED COAGULATION FACTORS

Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulphate R* (10 µg of protamine sulphate neutralises 1 IU of heparin). Prepare 1 to 10 and 1 to 100 dilutions of the preparation to be examined using *tris(hydroxymethyl)aminomethane buffer solution pH 7.5 R*. Place a series of polystyrene tubes in a water-bath at 37 °C and add to each tube 0.1 ml of *platelet-poor plasma R* and 0.1 ml of a suitable dilution of a phospholipid preparation to act as a platelet substitute. Allow to stand for 60 s. Add to each tube either 0.1 ml of 1 of the dilutions or 0.1 ml of the buffer solution (control tube). To each tube add immediately 0.1 ml of a 3.7 g/l solution of *calcium chloride R* previously heated to 37 °C, and measure, within 30 min of preparing the original dilution, the time that elapses between addition of the calcium chloride solution and the formation of a clot. The test is not valid unless the coagulation time measured for the control tube is 200 s to 350 s.

01/2008:20624

2.6.24. AVIAN VIRAL VACCINES: TESTS FOR EXTRANEOUS AGENTS IN SEED LOTS

GENERAL PROVISIONS

a) In the following tests, chickens and/or chicken material such as eggs and cell cultures shall be derived from chicken flocks free from specified pathogens (SPF) (*5.2.2*).

b) Cell cultures for the testing of extraneous agents comply with the requirements for the master cell seed of chapter *5.2.4. Cell cultures for the production of veterinary vaccines*, with the exception of the karyotype test and the tumorigenicity test, which do not have to be carried out.

c) In tests using cell cultures, precise specifications are given for the number of replicates, monolayer surface areas and minimum survival rate of the cultures. Alternative numbers of replicates and cell surface areas are possible as well, provided that a minimum of 2 replicates are used, the total surface area and the total volume of test substance applied are not less than that prescribed here and the survival rate requirements are adapted accordingly.

d) For a freeze-dried preparation, reconstitute using a suitable liquid. Unless otherwise stated or justified, the test substance must contain a quantity of virus equivalent to at least 10 doses of vaccine in 0.1 ml of inoculum.

e) If the virus of the seed lot would interfere with the conduct and sensitivity of the test, neutralise the virus in the preparation with a monospecific antiserum.

f) Monospecific antiserum and serum of avian origin used for cell culture or any other purpose, in any of these tests, shall be free of antibodies against and free from inhibitory effects on the organisms listed hereafter under 7. Antibody specifications for sera used in extraneous agents testing.

g) Where specified in a monograph or otherwise justified, if neutralisation of the virus of the seed lot is required but difficult to achieve, the *in vitro* tests described below are adapted, as required, to provide the necessary guarantees of freedom from contamination with an extraneous agent.

h) Other types of tests than those indicated may be used provided they are at least as sensitive as those indicated and of appropriate specificity. Nucleic acid amplification techniques (*2.6.21*) give specific detection for many agents and can be used after validation for sensitivity and specificity.

1. TEST FOR EXTRANEOUS AGENTS USING EMBRYONATED HENS' EGGS

Use a test substance, diluted if necessary, containing a quantity of neutralised virus equivalent to at least 10 doses of vaccine in 0.2 ml of inoculum. Suitable antibiotics may be added. Inoculate the test substance into 3 groups of 10 embryonated hens' eggs as follows:

- group 1: 0.2 ml into the allantoic cavity of each 9- to 11-day-old embryonated egg,
- group 2: 0.2 ml onto the chorio-allantoic membrane of each 9- to 11-day-old embryonated egg,
- group 3: 0.2 ml into the yolk sac of each 5- to 6-day-old embryonated egg.

Candle the eggs in groups 1 and 2 daily for 7 days and the eggs in group 3 for 12 days. Discard embryos that die during the first 24 h as non-specific deaths; the test is not valid unless at least 6 embryos in each group survive beyond the first 24 h after inoculation. Examine macroscopically for abnormalities all embryos which die more than 24 h after inoculation, or which survive the incubation period. Examine also the chorio-allantoic membranes of these eggs for any abnormality and test the allantoic fluids for the presence of haemagglutinating agents.

Carry out a further embryo passage. Pool separately material from live and from the dead and abnormal embryos. Inoculate each pool into 10 eggs for each route as described above, chorio-allantoic membrane material being inoculated onto chorio-allantoic membranes, allantoic fluids into the allantoic cavity and embryo material into the yolk sac. For eggs inoculated by the allantoic and chorio-allantoic routes, candle the eggs daily for 7 days, proceeding and examining the material as described above. For eggs inoculated by the yolk sac route, candle the eggs daily for 12 days, proceeding and examining the material as described above.

The seed lot complies with the test if no test embryo shows macroscopic abnormalities or dies from causes attributable to the seed lot and if examination of the chorio-allantoic membranes and testing of the allantoic fluids show no evidence of the presence of any extraneous agent.

2. TEST IN CHICKEN KIDNEY CELLS

Prepare 7 monolayers of chicken kidney cells, each monolayer having an area of about 25 cm^2. Maintain 2 monolayers as negative controls and treat these in the same way as the 5 monolayers inoculated with the test substance, as described below. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test substance onto each of the 5 monolayers. Allow adsorption for 1 h, add culture medium and incubate the cultures for a total of at least 21 days, subculturing at 4- to 7- day intervals. Each passage is made with pooled cells and fluids from all 5 monolayers after carrying out a freeze-thaw cycle. Inoculate 0.1 ml of pooled material onto each of 5 recently prepared monolayers of about 25 cm^2 each, at each passage. For the last passage, grow the cells also on a suitable substrate so as to obtain an area of about 10 cm^2 of cells from each of the monolayers for test A. The test is not valid if less than 80 per cent of the monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of contaminating agents in the test substance. At the end of the total incubation period, carry out the following procedures.

A. Fix and stain (with Giemsa or haematoxylin and eosin) about 10 cm^2 of confluent cells from each of the 5 monolayers. Examine the cells microscopically for any cytopathic effect, inclusion bodies, syncytial formation, or any other evidence of the presence of contaminating agents from the test substance.

B. Drain and wash about 25 cm^2 of cells from each of the 5 monolayers. Cover these cells with a 0.5 per cent suspension of washed chicken erythrocytes (using at least 1 ml of suspension for each 5 cm^2 of cells). Incubate the cells at 4 °C for 20 min and then wash gently in phosphate buffered saline pH 7.4. Examine the cells microscopically for haemadsorption attributable to the presence of a haemadsorbing agent in the test substance.

C. Test individual samples of the fluids from each cell culture using chicken erythrocytes for haemagglutination attributable to the presence of a haemagglutinating agent in the test substance.

The test is not valid if there are any signs of extraneous agents in the negative control cultures. The seed lot complies with the test if there is no evidence of the presence of any extraneous agent.

3. TEST FOR AVIAN LEUCOSIS VIRUSES

Prepare at least 13 replicate monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos that are known to be genetically susceptible to subgroups A, B and J of avian leucosis viruses and that support the growth of exogenous but not endogenous avian leucosis viruses (cells from C/E strain chickens are suitable). Each replicate shall have an area of about 50 cm^2.

Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of the test substance onto each of 5 of the replicate monolayers. Allow adsorption for 1 h, and add culture medium. Inoculate 2 of the replicate monolayers with subgroup A avian leucosis virus (not more than 10 $CCID_{50}$ in 0.1 ml), 2 with subgroup B avian leucosis virus (not more than 10 $CCID_{50}$ in 0.1 ml) and 2 with subgroup J avian leucosis virus (not more than 10 $CCID_{50}$ in 0.1 ml) as positive controls. Maintain not fewer than 2 non-inoculated replicate monolayers as negative controls.

Incubate the cells for a total of at least 9 days, subculturing at 3- to 4-day intervals. Retain cells from each passage level and harvest the cells at the end of the total incubation period. Wash cells from each passage level from each replicate and resuspend the cells at 10^7 cells per millilitre in barbital-buffered saline for subsequent testing by a Complement Fixation for Avian Leucosis (COFAL) test or in phosphate buffered saline for testing by Enzyme-Linked Immunosorbent Assay (ELISA). Then, carry out 3 cycles of freezing and thawing to release any group-specific antigen and perform a COFAL test or an ELISA test on each extract to detect group-specific avian leucosis antigen if present.

The test is not valid if group-specific antigen is detected in fewer than 5 of the 6 positive control replicate monolayers or if a positive result is obtained in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test replicate monolayers are inconclusive, then further subcultures of reserved portions of the fibroblast monolayers shall be made and tested until an unequivocal result is obtained. If a positive result is obtained for any of the test monolayers, then the presence of avian leucosis virus in the test substance has been detected.

The seed lot complies with the test if there is no evidence of the presence of any avian leucosis virus.

4. TEST FOR AVIAN RETICULOENDOTHELIOSIS VIRUS

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day old chick embryos or duck embryo fibroblasts from the tissues of 13- to 14-day-old embryos, each monolayer having an area of about 25 cm^2.

Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of the test substance onto each of 5 of the monolayers. Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with avian reticuloendotheliosis virus as positive controls (not more than 10 $CCID_{50}$ in 0.1 ml). Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cells for a total of at least 10 days, subculturing twice at 3- to 4-day intervals. The test is not valid if fewer than 3 of the 4 positive controls or fewer than 4 of the 5 test monolayers or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the fibroblasts on a suitable substrate so as to obtain an area of about 10 cm^2 of confluent fibroblasts from each of the original 11 monolayers for the subsequent test: test about 10 cm^2 of confluent fibroblasts derived from each of the original 11 monolayers by immunostaining for the presence of avian reticuloendotheliosis virus. The test is not valid if avian reticuloendotheliosis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the fibroblast monolayers shall be made and tested until an unequivocal result is obtained.

The seed lot complies with the test if there is no evidence of the presence of avian reticuloendotheliosis virus.

5. TEST FOR CHICKEN ANAEMIA VIRUS

Prepare eleven 20 ml suspensions of the MDCC-MSBI cell line or another cell line of equivalent sensitivity in 25 cm^2 cell culture flasks containing about 5×10^5 cells/ml. Inoculate 0.1 ml of test substance into each of 5 flasks. Inoculate 4 of the suspensions with 10 $CCID_{50}$ chicken anaemia virus as positive controls. Maintain not fewer than 2 non-inoculated suspensions. Maintain all the cell cultures for a total of at least 24 days, subculturing 8 times at 3- to 4-day intervals. During the subculturing the presence of chicken anaemia virus may be indicated by a metabolic colour change in the infected cultures, the culture fluids become red in comparison with the control cultures. Examine the cells microscopically for cytopathic effect. At this time or at the end of the incubation period, centrifuge the cells from each flask at low speed and resuspend at about 10^6 cells/ml and place 25 µl in each of 10 wells of a multi-well slide. Examine the cells by immunostaining.

The test is not valid if chicken anaemia virus is detected in fewer than 3 of the 4 positive controls or in any of the non-inoculated controls. If the results for more than 1 of the test suspensions are inconclusive, then further subcultures of reserved portions of the test suspensions shall be made and tested until an unequivocal result is obtained.

The seed lot complies with the test if there is no evidence of the presence of chicken anaemia virus.

6. TEST FOR EXTRANEOUS AGENTS USING CHICKS

Inoculate each of at least 10 chicks, with the equivalent of 100 doses of vaccine by the intramuscular route and with the equivalent of 10 doses by eye-drop. Chicks that are 2 weeks of age are used in the test except that if the seed virus is pathogenic for birds of this age, older birds may be used, if required and justified. In exceptional cases, for inactivated vaccines, the virus may be neutralised by specific antiserum if the seed virus is pathogenic for birds at the age of administration. Repeat these inoculations 2 weeks later. Observe the chicks for a period of 5 weeks from the day of the first inoculation. No antimicrobial agents shall be administered to the chicks during the test period. The test is not valid if fewer than 80 per cent of the chicks survive to the end of the test period.

Collect serum from each chick at the end of the test period. Test each serum sample for antibodies against each of the agents listed below (with the exception of the virus type of the seed lot) using one of the methods indicated for testing for the agent.

Clinical signs of disease in the chicks during the test period (other than signs attributable to the virus of the seed lot) and the detection of antibodies in the chicks after inoculation, (with the exception of antibodies to the virus of the seed lot) are classed as evidence of the presence of an extraneous agent in the seed lot.

It is recommended that sera from these birds is retained so that additional testing may be carried out if requirements change.

A. Standard tests

Agent	Type of test
Avian adenoviruses, group 1	SN, EIA, AGP
Avian encephalomyelitis virus	AGP, EIA
Avian infectious bronchitis virus	EIA, HI
Avian infectious laryngotracheitis virus	SN, EIA, IS
Avian leucosis viruses	SN, EIA
Avian nephritis virus	IS
Avian orthoreoviruses	IS, EIA
Avian reticuloendotheliosis virus	AGP, IS, EIA
Chicken anaemia virus	IS, EIA, SN
Egg drop syndrome virus	HI, EIA
Avian infectious bursal disease virus	Serotype 1: AGP, EIA, SN Serotype 2: SN
Influenza A virus	AGP, EIA, HI
Marek's disease virus	AGP
Newcastle disease virus	HI, EIA
Turkey rhinotracheitis virus	EIA
Salmonella pullorum	Agg

Agg: agglutination
AGP: agar gel precipitation
EIA: enzyme immunoassay (e.g. ELISA)
IS: immunostaining (e.g. fluorescent antibody)
HI: haemagglutination inhibition
SN: serum neutralisation

B. Additional tests for turkey extraneous agents

If the seed virus is of turkey origin or was propagated in turkey substrates, tests for antibodies against the following agents are also carried out.

Agent	Type of test
Chlamydia spp.	EIA
Avian infectious haemorrhagic enteritis virus	AGP
Avian paramyxovirus 3	HI
Avian infectious bursal disease virus type 2	SN

A test for freedom from turkey lympho-proliferative disease virus is carried out by intraperitoneal inoculation of twenty 4-week-old turkey poults. Observe the poults for 40 days. The test is not valid if more than 20 per cent of the poults die from non-specific causes. The seed lot complies with the test if sections of spleen and thymus taken from 10 poults 2 weeks after inoculation show no macroscopic or microscopic lesions (other than those attributable to the seed lot virus) and no poult dies from causes attributable to the seed lot.

C. Additional tests for duck extraneous agents

If the seed virus is of duck origin or was propagated in duck substrates, tests for antibodies against the following agents are also carried out.

Agent	Type of test
Chlamydia spp.	EIA
Duck and goose parvoviruses	SN, EIA
Duck enteritis virus	SN
Duck hepatitis virus type I	SN

The seed lot complies with the test if there is no evidence of the presence of any extraneous agent.

D. Additional tests for goose extraneous agents

If the seed virus is of goose origin or was prepared in goose substrates, tests for the following agents are also carried out.

Agent	Type of test
Duck and goose parvovirus	SN, EIA
Duck enteritis virus	SN
Goose haemorrhagic polyomavirus	test in goslings shown below or another suitable test

Inoculate subcutaneously the equivalent of at least 10 doses to each of ten 1-day-old susceptible goslings. Observe the goslings for 28 days. The test is not valid if more than 20 per cent of the goslings die from non-specific causes. The seed virus complies with the test if no gosling dies from causes attributable to the seed lot.

7. ANTIBODY SPECIFICATIONS FOR SERA USED IN EXTRANEOUS AGENTS TESTING

All batches of serum to be used in extraneous agents testing either to neutralise the vaccine virus (seed lot or batch of finished product) and all batches of avian serum used as a supplement for culture media used for tissue culture propagation, shall be shown to be free of antibodies against and free from inhibitory effects on the following micro-organisms by suitably sensitive tests:

Avian adenoviruses
Avian encephalomyelitis virus
Avian infectious bronchitis viruses
Avian infectious bursal disease virus types 1 and 2
Avian infectious haemorrhagic enteritis virus
Avian infectious laryngotracheitis virus
Avian leucosis viruses
Avian nephritis virus
Avian paramyxoviruses 1 to 9
Avian orthoreoviruses
Avian reticuloendotheliosis virus
Chicken anaemia virus
Duck enteritis virus
Duck hepatitis virus type I
Egg drop syndrome virus
Fowl pox virus
Influenza viruses
Marek's disease virus
Turkey herpesvirus
Turkey rhinotracheitis virus

Non-immune serum for addition to culture media can be assumed to be free of antibodies against any of these viruses if the agent is known not to infect the species of origin of the serum and it is not necessary to test the serum for such antibodies. Monospecific antisera for virus neutralisation can be assumed to be free of the antibodies against any of these viruses if it can be shown that the immunising antigen could not have been contaminated with antigens derived from that virus and if the virus is known not to infect the species of origin of the serum; it is not necessary to test the serum for such antibodies. It is not necessary to retest sera obtained from birds from SPF chicken flocks (*5.2.2*).

Batches of sera prepared for neutralising the vaccine virus must not be prepared from any passage level derived from the virus isolate used to prepare the master seed lot or from an isolate cultured in the same cell line.

01/2008:20625

2.6.25. AVIAN LIVE VIRUS VACCINES: TESTS FOR EXTRANEOUS AGENTS IN BATCHES OF FINISHED PRODUCT

GENERAL PROVISIONS

a) In the following tests, chickens and/or chicken material such as eggs and cell cultures shall be derived from chicken flocks free from specified pathogens (SPF) (*5.2.2*).

b) Cell cultures for the testing of extraneous agents comply with the requirements for the master cell seed of chapter *5.2.4. Cell cultures for the production of veterinary vaccines*, with the exception of the karyotype test and the tumorigenicity test, which do not have to be carried out.

c) In tests using cell cultures, precise specifications are given for the number of replicates, monolayer surface areas and minimum survival rate of the cultures. Alternative numbers of replicates and cell surface areas are possible as well, provided that a minimum of 2 replicates are used, the total surface area and the total volume of vaccine test applied are not less than that prescribed here and the survival rate requirements are adapted accordingly.

d) In these tests, use the liquid vaccine or reconstitute a quantity of the freeze-dried preparation to be tested with the liquid stated on the label or another suitable diluent such as water for injections. Unless otherwise stated or justified, the test substance contains the equivalent of 10 doses in 0.1 ml of inoculum.

e) If the vaccine virus would interfere with the conduct and sensitivity of the test, neutralise the virus in the preparation with a monospecific antiserum.

f) Where specified in a monograph or otherwise justified, if neutralisation of the vaccine virus is required but difficult to achieve, the *in vitro* tests described below are adapted, as required, to provide the necessary guarantees of freedom from contamination with an extraneous agent. Alternatively, or in addition to *in vitro* tests conducted on the batch, a test for extraneous agents may be conducted on chick sera obtained from testing the batch of vaccine, as decribed under 6. Test for extraneous agents using chicks of chapter *2.6.24. Test for extraneous agents in seed lots*.

g) Monospecific antiserum and serum of avian origin used for cell culture and any other purpose, in any of these tests, shall be free of antibodies against and free from inhibitory effects on the organisms listed under 7. Antibody specifications for sera used in extraneous agents testing (*2.6.24*).

h) Other types of tests than those indicated may be used provided they are at least as sensitive as those indicated and of appropriate specificity. Nucleic acid amplification techniques (*2.6.21*) give specific detection for many agents and can be used after validation for sensitivity and specificity.

1. TEST FOR EXTRANEOUS AGENTS USING EMBRYONATED HENS' EGGS

Prepare the test vaccine, diluted if necessary, to contain neutralised virus equivalent to 10 doses of vaccine in 0.2 ml of inoculum. Suitable antibiotics may be added. Inoculate the test vaccine into 3 groups of 10 embryonated hens' eggs as follows:

- group 1: 0.2 ml into the allantoic cavity of each 9- to 11-day-old embryonated egg,
- group 2: 0.2 ml onto the chorio-allantoic membrane of each 9- to 11-day-old embryonated egg,
- group 3: 0.2 ml into the yolk sac of each 5- to 6-day-old embryonated egg.

Candle the eggs in groups 1 and 2 daily for 7 days and the eggs in group 3 for 12 days. Discard embryos that die during the first 24 h as non-specific deaths; the test is not valid unless at least 6 embryos in each group survive beyond the first 24 h after inoculation. Examine macroscopically for abnormalities all embryos which die more than 24 h after inoculation, or which survive the incubation period. Examine also the chorio-allantoic membranes of these eggs for any abnormality and test the allantoic fluids for the presence of haemagglutinating agents.

Carry out a further embryo passage. Pool separately material from live and from the dead and abnormal embryos. Inoculate each pool into 10 eggs for each route as described above, chorio-allantoic membrane material being inoculated onto chorio-allantoic membranes, allantoic fluids into the allantoic cavity and embryo material into the yolk sac. For eggs inoculated by the allantoic and chorio-allantoic routes, candle the eggs daily for 7 days, proceeding and examining the material as described above. For eggs inoculated by the yolk sac route, candle the eggs daily for 12 days, proceeding and examining the material as described above.

The batch of vaccine complies with the test if no test embryo shows macroscopic abnormalities or dies from causes attributable to the vaccine and if examination of the chorio-allantoic membranes and testing of the allantoic fluids show no evidence of the presence of extraneous agents.

2. TEST IN CHICKEN EMBRYO FIBROBLAST CELLS

Prepare 7 monolayers of primary or secondary chicken embryo fibroblasts, from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 cm^2. Maintain 2 monolayers as negative controls and treat these in the same way as the 5 monolayers inoculated with the test vaccine, as described below. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers. Allow adsorption for 1 h and add culture medium. Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made with pooled cells and fluids from all 5 monolayers after carrying out a freeze-thaw cycle. Inoculate 0.1 ml of pooled material onto each of 5 recently prepared monolayers of chicken embryo fibroblast cells, each monolayer having an area of about 25 cm^2 each as before. For the last passage, grow the cells also on a suitable substrate so as to obtain an area of about 10 cm^2 of cells from each of the monolayers, for test A. The test is not valid if less than 80 per cent of the test monolayers, or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of contaminating agents in the test vaccine. At the end of the total incubation period, carry out the following procedures.

A. Fix and stain (with Giemsa or haematoxylin and eosin) about 10 cm^2 of confluent cells from each of the 5 original monolayers. Examine the cells microscopically for any cytopathic effect, inclusion bodies, syncytial formation, or any other evidence of the presence of a contaminating agent from the test vaccine.

B. Drain and wash about 25 cm^2 of cells from each of the 5 monolayers. Cover these cells with a 0.5 per cent suspension of washed chicken red blood cells (using at least 1 ml of suspension for each 5 cm^2 of cells). Incubate the cells at 4 °C for 20 min and then wash gently in phosphate buffered saline pH 7.4. Examine the cells microscopically for haemadsorption attributable to the presence of a haemadsorbing agent in the test vaccine.

C. Test individually samples of the fluid from each cell culture using chicken red blood cells for haemagglutination attributable to the presence of a haemagglutinating agent in the test vaccine.

The test is not valid if there are any signs of extraneous agents in the negative control cultures. The batch of vaccine complies with the test if there is no evidence of the presence of any extraneous agent.

3. TEST FOR EGG DROP SYNDROME VIRUS

Prepare 11 monolayers of chicken embryo liver cells, from the tissues of 14- to 16-day-old embryos, each monolayer having an area of about 25 cm^2. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, add culture medium. Inoculate 4 of the monolayers with a suitable strain of egg drop syndrome virus (not more than 10 $CCID_{50}$ in 0.1 ml) to serve as positive control monolayers. Maintain 2 non-inoculated monolayers as negative control monolayers.

Incubate the cells for a total of at least 21 days, subculturing every 4-5 days. Each passage is made as follows: carry out a freeze-thaw cycle; prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers; inoculate 0.1 ml of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of chicken embryo liver cells, each monolayer having an area of about 25 cm^2 as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures at frequent intervals throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of a contaminating agent in the test vaccine. At the end of the total incubation period, carry out the following procedure: test separately, cell culture fluid from the test monolayers, positive control monolayers and negative control monolayers, using chicken red blood cells, for haemagglutination attributable to the presence of haemagglutinating agents.

The test is not valid if egg drop syndrome virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of egg drop syndrome virus or any other extraneous agent.

4. TEST FOR MAREK'S DISEASE VIRUS

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 cm^2. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain of Marek's disease virus (not more than 10 $CCID_{50}$ in 0.1 ml) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: trypsinise the cells, prepare separate pools of the cells from the test monolayers, from the positive control monolayers and from the negative control monolayers. Mix an appropriate quantity of each with a suspension of freshly prepared primary or secondary chick embryo fibroblasts and prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of a contaminating agent in the test vaccine.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm^2 of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm^2 of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of Marek's disease virus. The test is not valid if Marek's disease virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive.

The batch of vaccine complies with the test if there is no evidence of the presence of Marek's disease virus or any other extraneous agent.

5. TESTS FOR TURKEY RHINOTRACHEITIS VIRUS

A. In chicken embryo fibroblasts

NOTE: this test can be combined with Test 2 by using the same test monolayers and negative controls, for all stages up to the final specific test for turkey rhinotracheitis virus on cells prepared from the last subculture.

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 cm^2. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain of turkey rhinotracheitis virus as positive controls (not more than 10 $CCID_{50}$ in 0.1 ml). Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle; prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers; inoculate 0.1 ml of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of chicken embryo fibroblasts cells, each monolayer having an area of about 25 cm^2 as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm^2 of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm^2 of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of turkey rhinotracheitis virus. The test is not valid if turkey rhinotracheitis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for both of

the 2 test monolayers are inconclusive then further subcultures of reserved portions of the fibroblasts shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of turkey rhinotracheitis virus or any other extraneous agent.

B. In Vero cells

Prepare 11 monolayers of Vero cells, each monolayer having an area of about 25 cm^2. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain of turkey rhinotracheitis virus (not more than 10 $CCID_{50}$ in 0.1 ml) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle. Prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers. Inoculate 0.1 ml of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of Vero cells, each monolayer having an area of about 25 cm^2 as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm^2 of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm^2 of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of turkey rhinotracheitis virus. The test is not valid if turkey rhinotracheitis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of turkey rhinotracheitis virus or any other extraneous agent.

6. TEST FOR CHICKEN ANAEMIA VIRUS

Prepare eleven 20 ml suspensions of the MDCC-MSBI cell line or another cell line of equivalent sensitivity in 25 cm^2 flasks containing about 5×10^5 cells/ml. Inoculate 0.1 ml of test vaccine into each of 5 of these flasks. Inoculate 4 other suspensions with 10 $CCID_{50}$ chicken anaemia virus as positive controls. Maintain not fewer than 2 non-inoculated suspensions. Maintain all the cell cultures for a total of at least 24 days, subculturing 8 times at 3- to 4-day intervals. During the subculturing the presence of chicken anaemia virus may be indicated by a metabolic colour change in the infected cultures, the culture fluids becoming red in comparison with the control cultures. Examine the cells microscopically for cytopathic effect. At this time or at the end of the incubation period, centrifuge the cells from each flask at low speed, resuspend at about 10^6 cells per millilitre and place 25 µl in each of 10 wells of a multi-well slide. Examine the cells by immunostaining.

The test is not valid if chicken anaemia virus is detected in fewer than 3 of the 4 positive controls or in any of the non-inoculated controls. If the results for more than 1 of the test suspensions are inconclusive then further subcultures of reserved portions of the test suspensions shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of chicken anaemia virus.

7. TEST FOR DUCK ENTERITIS VIRUS

This test is carried out for vaccines prepared on duck or goose substrates.

Prepare 11 monolayers of primary or secondary Muscovy duck embryo liver cells, from the tissues of 21- or 22-day-old embryos, each monolayer having an area of about 25 cm^2. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h and add culture medium. Inoculate 4 of the monolayers with a suitable strain of duck enteritis virus (not more than 10 $CCID_{50}$ in 0.1 ml) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: trypsinise the cells and prepare separate pools of the cells from the test monolayers, from the positive control monolayers and from the negative control monolayers. Mix a portion of each with a suspension of freshly prepared primary or secondary Muscovy duck embryo liver cells to prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm^2 of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm^2 of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of duck enteritis virus. The test is not valid if duck enteritis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of duck enteritis virus or any other extraneous agent.

8. TEST FOR DUCK AND GOOSE PARVOVIRUSES

This test is carried out for vaccines prepared on duck or goose substrates.

Prepare a suspension of sufficient primary or secondary Muscovy duck embryo fibroblasts from the tissues of 16- to 18-day-old embryos, to obtain not fewer than 11 monolayers, each having an area of about 25 cm^2. Inoculate 0.5 ml of test vaccine into an aliquot of cells for 5 monolayers and seed into 5 replicate containers to form 5 test monolayers. Inoculate 0.4 ml of a suitable strain of duck parvovirus (not more than 10 $CCID_{50}$ in 0.1 ml) into an aliquot of cells for 4 monolayers and seed into 4 replicate containers to form 4 positive control monolayers. Prepare 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle. Prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers. Inoculate 0.5 ml, 0.4 ml and 0.2 ml of the pooled materials into aliquots of a fresh suspension

of sufficient primary or secondary Muscovy duck embryo fibroblast cells to prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm^2 of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm^2 of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of duck or goose parvovirus. The test is not valid if duck parvovirus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive.

The batch of vaccine complies with the test if there is no evidence of the presence of duck (or goose) parvovirus or any other extraneous agent.

01/2008:20626

2.6.26. TEST FOR ANTI-D ANTIBODIES IN HUMAN IMMUNOGLOBULIN FOR INTRAVENOUS ADMINISTRATION

MATERIALS

Phosphate-buffered saline (PBS). Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R*, 0.2 g of *potassium dihydrogen phosphate R* and 0.2 g of *sodium azide R* in *water R* and dilute to 1000 ml with the same solvent.

Papain solution. Use serological grade papain from a commercial source, the activity of which has been validated.

Red blood cells. Use pooled red blood cells from not fewer than 3 donors of group OR_2R_2 and 3 donors of group Orr respectively. Wash the cells 4 times with PBS or until the supernatant is clear. Centrifuge the cells at 1800 *g* for 5 min to pack. Treat the packed red cells with papain solution according to the manufacturer's instructions. Store in Alsever's solution for not more than 1 week.

Microtitre plates. Use V-bottomed rigid micro-titre plates.

Reference standards. Immunoglobulin (anti-D antibodies test) BRP and *Immunoglobulin (anti-D antibodies test negative control) BRP* are suitable for use as the reference preparation and negative control, respectively.

METHOD

Reference preparation and negative control solutions. Reconstitute the reference preparation and the negative control according to instructions. Dilute the reconstituted preparations with an equal volume of PBS containing 2 g/l of *bovine albumin R* and then prepare a further 7 serial two-fold dilutions using PBS containing 2 g/l of *bovine albumin R* to give a total dilution range from 1/2 to 1/256. Make 2 independent sets of dilutions for each preparation. Add 20 µl of each dilution to the microtitre plate.

Test solutions. Initially dilute the test samples to give a starting immunoglobulin G (IgG) concentration of 25 g/l using PBS containing 2 g/l of *bovine albumin R* and then prepare a further 7 serial two-fold dilutions using PBS containing 2 g/l of *bovine albumin R* to give a total dilution range from 1/2 to 1/256. Make 2 independent sets of dilutions for each test sample. Add 20 µl of each dilution to the microtitre plate.

Prepare 3 per cent *V/V* suspensions of papain-treated D-positive (OR_2R_2) and D-negative (Orr) red cells in PBS containing 2 g/l of *bovine albumin R*. Add 20 µl of D-positive cells to one dilution series of each of the test sample, the reference preparation and the negative control, and 20 µl of D-negative cells to the other dilution series of each of the test samples, the reference preparation and the negative control. Mix by shaking the plate on a shaker for 10 s.

Centrifuge the plate at 80 *g* for 1 min to pellet the cells.

Place the plate at an angle of approximately 70°. Read after 4-5 min (or until the cells have streamed in the wells containing the negative control and the wells where the D-negative cells have been added). A cell button at the bottom of the well indicates a positive result. A stream of cells represents a negative result.

Record the endpoint titre as the reciprocal of the highest dilution that gives rise to a positive result.

The titre of the preparation to be examined is not greater than the titre of the reference preparation.

01/2008:20627

2.6.27. MICROBIOLOGICAL CONTROL OF CELLULAR PRODUCTS

This test has been shown to be preferable to the test for sterility (*2.6.1*) for certain cellular products, since it has better sensitivity, has a broader range, and is more rapid. It is applied instead of the test for sterility (*2.6.1*) where prescribed in a monograph. It may be carried out manually or using an automated system.

GENERAL PRECAUTIONS

The test is carried out under aseptic conditions according to current regulations for potentially infective material.

The precautions taken to avoid contamination are such that they do not affect any micro-organisms that are to be revealed in the test. The test is performed under working conditions that are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls.

GROWTH PROMOTION TEST

Use at least 2 suitable enriched culture media (for example, blood culture media) intended for detection of fungi and aerobic and anaerobic bacteria.

Confirm the sterility of each batch of medium by the incubation of representative containers at 35-37 °C for not less than 7 days.

Each batch of medium is tested by the supplier and/or the user for its growth-promoting capacities by inoculating duplicate test containers of each medium with 10-100 viable micro-organisms of each of the strains listed in Table 2.6.27.-1, and incubating for either 7 days for automated detection or 14 days for visual detection of microbial growth at 35-37 °C. The test media are satisfactory if there is clear evidence of growth in all inoculated media containers within this period.

Table 2.6.27.-1. – *Micro-organisms used for growth promotion*

Aerobic medium	
Staphylococcus aureus	for example, ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518
Bacillus subtilis	for example, ATCC 6633, CIP 52.62, NCIMB 8054
Pseudomonas aeruginosa	for example, ATCC 9027, NCIMB 8626, CIP 82.118
Candida albicans	for example, ATCC 10231, IP 48.72, NCPF 3179
Aspergillus niger	for example, ATCC 16404, IP 1431.83, IMI 149007
Anaerobic medium	
Clostridium sporogenes	for example, ATCC 19404, CIP 79.3, NCTC 532 or ATCC 11437
Bacteroides fragilis	for example, ATCC 25285, CIP 77.16, NCTC 9343

METHOD VALIDATION

Depending on the type of product, its method of preparation, the inoculum volume used and the type of test system, the need for validation in the presence of the type of preparation to be examined must be considered. Unless otherwise justified and authorised, the test system is validated with respect to specificity (absence of false positive results), sensitivity (limit of detection) and reproducibility. During validation, particularly to determine the limit of detection, the test is carried out using the preparation deliberately contaminated to different degrees with the following micro-organisms, chosen for the likelihood of contamination and their growth requirements:

– *Aspergillus niger*, for example, ATCC 16404, IP 1431.83, IMI 149007;
– *Bacillus subtilis*, for example, ATCC 6633, CIP 52.62, NCIMB 8054;
– *Candida albicans*, for example, ATCC 10231, IP 48.72, NCPF 3179;
– *Clostridium sporogenes*, for example, ATCC 19404, CIP 79.3, NCTC 532 or ATCC 11437;
– *Propionibacterium acnes*, for example, ATCC 11827;
– *Pseudomonas aeruginosa*, for example, ATCC 9027, NCIMB 8626, CIP 82.118;
– *Staphylococcus aureus*, for example, ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518;
– *Streptococcus pyogenes*, for example, ATCC 19615, CIP 1042.26, NCIMB 13285;
– *Yersinia enterocolitica*, for example, ATCC 9610, CIP 80.27, NCTC 12982.

It may be necessary to modify the list of micro-organisms depending on the origin of the cells and any micro-organisms previously found or associated with the particular type of cells.

Other approaches to validation may also be used, for example, interlaboratory comparison.

TESTING OF THE PREPARATION TO BE EXAMINED

Sample. A representative sample including cells and/or medium is tested. The sample is added to the culture medium as soon as possible after collection. If it is not added promptly after collection, it is stored at 5 ± 3 °C to avoid phagocytosis of micro-organisms by cells present in certain types of products (for example, neutrophils).

For haematopoietic products, the minimum amount to be used for the test depending on the total volume of the product (V ml) is shown below.

Total product volume (millilitres)	Inoculum volume
$V \geq 10$	1 per cent of total volume
$1 \leq V < 10$	100 µl
$V < 1$	Not applicable

For haematopoietic products that require dilution before freezing, the inoculum volume must be increased by the dilution factor. For other cellular products, suitable minimum amounts are defined in terms of volume or number of doses.

Analysis. Samples are inoculated into containers of culture medium as soon as possible after collection and incubated at 35-37 °C for not less than 7 or 14 days, depending on the detection system used. A suitable proportion of the inoculum is added to the medium to be incubated in aerobic conditions and the remainder of the inoculum to the medium to be incubated in anaerobic conditions.

OBSERVATION AND INTERPRETATION OF RESULTS

Examine media, visually or with automated systems at least daily, and at the end of the observation period for evidence of microbial growth. If no growth is observed during or at the end of the observation period, the product is 'culture negative' at the limit of detection. If growth is observed in a valid test, the product is 'culture positive'; the contaminant is identified to a suitable taxonomic level (genus, species) and an antibiogram is established.

2.7. BIOLOGICAL ASSAYS

01/2008:20701

2.7.1. IMMUNOCHEMICAL METHODS

Immunochemical methods are based on the selective, reversible and non-covalent binding of antigens by antibodies. These methods are employed to detect or quantify either antigens or antibodies. The formation of an antigen-antibody complex may be detected, and the amount of complex formed may be measured by a variety of techniques. The provisions of this general method apply to immunochemical methods using labelled or unlabelled reagents, as appropriate.

The results of immunochemical methods depend on the experimental conditions and the nature and quality of the reagents used. It is essential to standardise the components of an immunoassay and to use, wherever available, international reference preparations for immunoassays.

The reagents necessary for many immunochemical methods are available as commercial assay kits, that is, a set including reagents (particularly the antigen or the antibody) and materials intended for the *in vitro* estimation of a specified substance as well as instructions for their proper use. The kits are used in accordance with the manufacturers' instructions; it is important to ascertain that the kits are suitable for the analysis of the substance to be examined, with particular reference to selectivity and sensitivity. Guidance concerning immunoassay kits is provided by the World Health Organisation, Technical Report Series 658 (1981).

METHODS IN WHICH A LABELLED ANTIGEN OR A LABELLED ANTIBODY IS USED

Methods using labelled substances may employ suitable labels such as enzymes, fluorophores, luminophores and radioisotopes. Where the label is a radioisotope, the method is described as a "radio-immunoassay". The recommendations for the measurement of radioactivity given in the monograph on *Radiopharmaceutical Preparations (0125)* are applicable to immunoassays involving radioisotopes. All work with radioactive materials must be carried out in conformity with national legislation and internationally accepted codes of practice for protection against radiation hazards.

METHODS IN WHICH AN UNLABELLED ANTIGEN OR ANTIBODY IS USED

Immunoprecipitation methods

Immunoprecipitation methods include flocculation and precipitation reactions. When a solution of an antigen is mixed with its corresponding antibody under suitable conditions, the reactants form flocculating or precipitating aggregates. The ratio of the reactants which gives the shortest flocculation time or the most marked precipitation is called the optimal ratio, and is usually produced by equivalent amounts of antigen and antibody. Immunoprecipitation can be assessed visually or by light-scattering techniques (nephelometric or turbidimetric assay). An increase in sensitivity can be obtained by using antigen- or antibody-coated particles (e.g. latex) as reactants.

In flocculation methods, stepwise dilutions of one of the reactants is usually used whereas, in immunodiffusion (ID) methods, the dilution is obtained by diffusion in a gel medium: concentration gradients of one or both of the reactants are obtained, thus creating zones in the gel medium where the ratio of the reactants favours precipitation. While flocculation methods are performed in tubes, immunodiffusion methods may be performed using different supports such as tubes, plates, slides, cells or chambers.

Where the immunoprecipitating system consists of one antigen combining with its corresponding antibody, the system is referred to as *simple*; when it involves related but not serologically identical reactants, the system is *complex* and where several serologically unrelated reactants are involved, the system is *multiple*.

In *simple diffusion methods*, a concentration gradient is established for only one of the reactants diffusing from an external source into the gel medium containing the corresponding reactant at a comparatively low concentration.

Single radial immunodiffusion (SRID) is a simple quantitative immunodiffusion technique. When the equilibrium between the external and the internal reactant has been established, the circular precipitation area, originating from the site of the external reactant, is directly proportional to the amount of the antigen applied and inversely proportional to the concentration of the antibody in the gel.

In *double diffusion methods*, concentration gradients are established for both reactants. Both antigen and antibody diffuse from separate sites into an initially immunologically neutral gel.

Comparative double diffusion methods are used for qualitatively comparing various antigens versus a suitable antibody or vice versa. The comparison is based on the presence or absence of interaction between the precipitation patterns. Reactions of identity, non-identity or partial identity of antigens/antibodies can be distinguished.

Immunoelectrophoretic methods

Immunoelectrophoresis (IE) is a qualitative technique combining 2 methods: gel electrophoresis followed by immunodiffusion.

Crossed immunoelectrophoresis is a modification of the IE method. It is suitable both for qualitative and quantitative analysis. The first part of the procedure is an ordinary gel electrophoresis, after which a longitudinal gel strip, containing the separated fractions to be determined, is cut out and transferred to another plate. The electrophoresis in the second direction is carried out perpendicular to the previous electrophoretic run in a gel containing a comparatively low concentration of antibodies corresponding to the antigens. For a given antibody concentration and gel thickness, the relationship between the area of the respective precipitation peaks and the amount of the corresponding antigen is linear.

Electroimmunoassay, often referred to as *rocket immuno-electrophoresis* is a rapid quantitative method for determining antigens with a charge differing from that of the antibodies or vice versa. The electrophoresis of the antigen to be determined is carried out in a gel containing a comparatively lower concentration of the corresponding antibody. The test material and dilutions of a standard antigen used for calibration are introduced into different wells in the gel. During electrophoresis, migrating peak-shaped precipitation zones originating from the wells are developed. The front of the precipitate becomes stationary when the antigen is no longer in excess. For a given antibody concentration, the relationship between the distance travelled by the precipitate and the amount of antigen applied is linear.

Counter-immunoelectrophoresis is a rapid quantitative method allowing concentration gradients of external antigen and external antibody to be established in an electric field depending on the different charges. Dilutions of a

standard for calibration and dilutions of the test material are introduced into a row of wells in a gel and a fixed amount of the corresponding reactant is introduced into an opposite row of wells. The titre of the test material may be determined as the highest dilution showing a precipitation line.

A number of modifications of crossed immunoelectrophoresis and electroimmunoassay methods exist.

Other techniques combine separation of antigens by molecular size and serological properties.

Visualisation and characterisation of immunoprecipitation lines

These may be performed by selective or non-selective stains, by fluorescence, by enzyme or isotope labelling or other relevant techniques. Selective staining methods are usually performed for characterisation of non-protein substances in the precipitates.

In translucent gels such as agar or agarose, the precipitation line becomes clearly visible in the gel, provided that the concentration of each of the reactants is appropriate.

VALIDATION OF THE METHOD

Validation criteria

A quantitative immunochemical method is not valid unless:

1) The antibody or antigen does not significantly discriminate between the test and standard. For a labelled reactant, the corresponding reactant does not significantly discriminate between the labelled and unlabelled compound,

2) The method is not affected by the assay matrix, that is, any component of the test sample or its excipients, which can vary between samples. These may include high concentrations of other proteins, salts, preservatives or contaminating proteolytic activity,

3) The limit of quantitation is below the acceptance criteria stated in the individual monograph,

4) The precision of the assay is such that the variance of the results meets the requirements stated in the individual monographs,

5) The order in which the assay is performed does not give rise to systematic errors.

Validation methods

In order to verify these criteria, the validation design includes the following elements:

1) The assay is performed at least in triplicate,

2) The assay includes at least 3 different dilutions of the standard preparation and 3 dilutions of sample preparations of presumed activity similar to the standard preparation,

3) The assay layout is randomised,

4) If the test sample is presented in serum or formulated with other components, the standard is likewise prepared,

5) The test includes the measurement of non-specific binding of the labelled reactant,

6) For displacement immunoassay:

(a) maximum binding (zero displacement) is determined,

(b) dilutions cover the complete response range from values close to non-specific binding to maximum binding, preferably for both standard and test preparations.

STATISTICAL CALCULATION

To analyse the results, response curves for test and standard may be analysed by the methods described in *5.3. Statistical Analysis of Results of Biological Assays and Tests*.

Significant non-parallelism indicates that the antibody or antigen discriminates between test and standard, and the results are not valid.

In displacement immunoassays, the values for non-specific binding and maximum displacement at high test or standard concentration must not be significantly different. Differences may indicate effects due to the matrix, either inhibition of binding or degradation of tracer.

2.7.2. MICROBIOLOGICAL ASSAY OF ANTIBIOTICS

The potency of an antibiotic is estimated by comparing the inhibition of growth of sensitive micro-organisms produced by known concentrations of the antibiotic to be examined and a reference substance.

The reference substances used in the assays are substances whose activity has been precisely determined with reference to the corresponding international standard or international reference preparation.

The assay must be designed in a way that will permit examination of the validity of the mathematical model on which the potency equation is based. If a parallel-line model is chosen, the 2 log dose-response (or transformed response) lines of the preparation to be examined and the reference preparation must be parallel; they must be linear over the range of doses used in the calculation. These conditions must be verified by validity tests for a given probability, usually $P = 0.05$. Other mathematical models, such as the slope ratio model, may be used provided that proof of validity is demonstrated.

Unless otherwise stated in the monograph, the confidence limits ($P = 0.95$) of the assay for potency are not less than 95 per cent and not more than 105 per cent of the estimated potency.

Carry out the assay by method A or method B.

A. DIFFUSION METHOD

Liquefy a medium suitable for the conditions of the assay and inoculate it at a suitable temperature, for example 48 °C to 50 °C for vegetative forms, with a known quantity of a suspension of micro-organisms sensitive to the antibiotic to be examined, such that clearly defined zones of inhibition of suitable diameter are produced with the concentrations of the antibiotic used for the assay. Immediately pour into Petri dishes or large rectangular dishes a quantity of the inoculated medium to form a uniform layer 2 mm to 5 mm thick. Alternatively, the medium may consist of 2 layers, only the upper layer being inoculated.

Store the dishes so that no appreciable growth or death of the micro-organisms occurs before the dishes are used and so that the surface of the medium is dry at the time of use.

Using the solvent and the buffer solution indicated in Table 2.7.2.-1, prepare solutions of the reference substance and of the antibiotic to be examined having known concentrations and presumed to be of equal activity. Apply the solutions to the surface of the medium, for example, in sterile cylinders of porcelain, stainless steel or other suitable material, or in cavities prepared in the agar. The same volume of solution must be added to each cylinder or cavity. Alternatively, use sterile absorbent paper discs of

suitable quality; impregnate the discs with the solutions of the reference substance or the solutions of the antibiotic to be examined and place on the surface of the agar.

In order to assess the validity of the assay, use not fewer than 3 doses of the reference substance and 3 doses of the antibiotic to be examined having the same presumed activity as the doses of the reference substance. It is preferable to use a series of doses in geometric progression. In routine assays when the linearity of the system has been demonstrated over an adequate number of experiments using a three-point assay, a two-point assay may be sufficient, subject to agreement by the competent authority. However, in all cases of dispute, a three-point assay as described above must be applied.

Arrange the solutions on each Petri dish or on each rectangular dish according to a statistically suitable design, except for small Petri dishes that cannot accommodate more than 6 solutions, arrange the solutions of the antibiotic to be examined and the solutions of the reference substance in an alternate manner to avoid interaction of the more concentrated solutions.

Incubate at a suitable temperature for about 18 h. A period of diffusion prior to incubation, usually 1 h to 4 h, at room temperature or at about 4 °C, as appropriate, may be used to minimise the effects of the variation in time between the application of the solutions and to improve the regression slope.

Measure the diameters with a precision of at least 0.1 mm or the areas of the circular inhibition zones with a corresponding precision and calculate the potency using appropriate statistical methods.

Use in each assay the number of replications per dose sufficient to ensure the required precision. The assay may be repeated and the results combined statistically to obtain the required precision and to ascertain whether the potency of the antibiotic to be examined is not less than the minimum required.

B. TURBIDIMETRIC METHOD

Inoculate a suitable medium with a suspension of the chosen micro-organism having a sensitivity to the antibiotic to be examined such that a sufficiently large inhibition of microbial growth occurs in the conditions of the test. Use a known quantity of the suspension chosen so as to obtain a readily measurable opacity after an incubation period of about 4 h.

Use the inoculated medium immediately after its preparation.

Using the solvent and the buffer solution indicated in Table 2.7.2.-2 prepare solutions of the reference substance and of the antibiotic to be examined having known concentrations presumed to be of equal activity.

In order that the validity of the assay may be assessed, use not fewer than 3 doses of the reference substance and 3 doses of the antibiotic to be examined having the same presumed activity as the doses of the reference substance. It is preferable to use a series of doses in geometric progression. In order to obtain the required linearity, it may be necessary to select from a large number 3 consecutive doses, using corresponding doses for the reference substance and the antibiotic to be examined.

Distribute an equal volume of each of the solutions into identical test-tubes and add to each tube an equal volume of inoculated medium (for example, 1 ml of the solution and 9 ml of the medium). For the assay of tyrothricin add 0.1 ml of the solution to 9.9 ml of inoculated medium.

Prepare at the same time 2 control tubes without antibiotic, both containing the inoculated medium and to one of which is added immediately 0.5 ml of *formaldehyde R*. These tubes are used to set the optical apparatus used to measure the growth.

Place all the tubes, randomly distributed or in a Latin square or randomised block arrangement, in a water-bath or other suitable apparatus fitted with a means of bringing all the tubes rapidly to the appropriate incubation temperature and maintain them at that temperature for 3 h to 4 h, taking precautions to ensure uniformity of temperature and identical incubation time.

After incubation, stop the growth of the micro-organisms by adding 0.5 ml of *formaldehyde R* to each tube or by heat treatment and measure the opacity to 3 significant figures using suitable optical apparatus. Alternatively use a method which allows the opacity of each tube to be measured after exactly the same period of incubation.

Calculate the potency using appropriate statistical methods.

Linearity of the dose-response relationship, transformed or untransformed, is often obtained only over a very limited range. It is this range which must be used in calculating the activity and it must include at least 3 consecutive doses in order to permit linearity to be verified. In routine assays when the linearity of the system has been demonstrated over an adequate number of experiments using a three-point assay, a two-point assay may be sufficient, subject to agreement by the competent authority. However, in all cases of dispute, a three-point assay must be applied.

Use in each assay the number of replications per dose sufficient to ensure the required precision. The assay may be repeated and the results combined statistically to obtain the required precision and to ascertain whether the potency of the antibiotic to be examined is not less than the minimum required.

The following section is published for information.

Recommended micro-organisms

The following text details the recommended micro-organisms and the conditions of use. Other micro-organisms may be used provided that they are shown to be sensitive to the antibiotic to be examined and are used in appropriate media and appropriate conditions of temperature and pH. The concentrations of the solutions used should be chosen so as to ensure that a linear relationship exists between the logarithm of the dose and the response in the conditions of the test.

Preparation of inocula. *Bacillus cereus* var. *mycoides*; *Bacillus subtilis*; *Bacillus pumilus*. Spore suspensions of the organisms to be used as inocula are prepared as follows.

Grow the organism at 35-37 °C for 7 days on the surface of a suitable medium to which has been added 0.001 g/l of *manganese sulphate R*. Using sterile *water R*, wash off the growth, which consists mainly of spores. Heat the suspension at 70 °C for 30 min and dilute to give an appropriate concentration of spores, usually 10×10^6 to 100×10^6 per millilitre. The spore suspensions may be stored for long periods at a temperature not exceeding 4 °C.

Alternatively, spore suspensions may be prepared by cultivating the organisms in medium C at 26 °C for 4-6 days, then adding, aseptically, sufficient *manganese sulphate R* to give a concentration of 0.001 g/l and incubating for a further 48 h. Examine the suspension microscopically to ensure that adequate spore formation has taken place (about 80 per cent) and centrifuge. Re-suspend the sediment in sterile *water R* to give a concentration of 10×10^6 to 100×10^6 spores per millilitre, and then heat to 70 °C for 30 min. Store the suspension at a temperature not exceeding 4 °C.

Bordetella bronchiseptica. Grow the test organism on medium B at 35-37 °C for 16-18 h. Wash off the bacterial growth with sterile *water R* and dilute to a suitable opacity.

Staphylococcus aureus; *Klebsiella pneumoniae*; *Escherichia coli*; *Micrococcus luteus*; *Staphylococcus epidermidis.* Prepare as described above for *B. bronchiseptica* but using medium A and adjusting the opacity to one which has been shown to produce a satisfactory dose-response relationship in the turbidimetric assay, or to produce clearly defined zones of inhibition of convenient diameter in the diffusion assay, as appropriate.

Saccharomyces cerevisiae; *Candida tropicalis.* Grow the test organism on medium F at 30-37 °C for 24 h. Wash off the growth with a sterile 9 g/l solution of *sodium chloride R*. Dilute to a suitable opacity with the same solution.

Buffer solutions. Buffer solutions having a pH between 5.8 and 8.0 are prepared by mixing 50.0 ml of *0.2 M potassium dihydrogen phosphate R* with the quantity of *0.2 M sodium hydroxide* indicated in Table 2.7.2.-3. Dilute with freshly prepared *distilled water R* to produce 200.0 ml.

Table 2.7.2.-3.

pH	*0.2 M Sodium hydroxide* (ml)
5.8	3.72
6.0	5.70
6.2	8.60
6.4	12.60
6.6	17.80
6.8	23.65
7.0	29.63
7.2	35.00
7.4	39.50
7.6	42.80
7.8	45.20
8.0	46.80

These buffer solutions are used for all microbiological assays shown in Table 2.7.2.-1 with the exception of bleomycin sulphate and amphotericin B.

For bleomycin sulphate, prepare the buffer solution pH 6.8 as follows: dissolve 6.4 g of *potassium dihydrogen phosphate R* and 18.9 g of *disodium hydrogen phosphate R* in *water R* and dilute to 1000 ml with *water R*.

For amphotericin B, prepare the 0.2 M phosphate buffer solution pH 10.5 as follows: dissolve 35 g of *dipotassium hydrogen phosphate R* in 900 ml of *water R*, add 20 ml of *1 M sodium hydroxide* and dilute to 1000.0 ml with *water R*.

Culture media. The following media or equivalent media may be used.

Medium A

Peptone	6 g
Pancreatic digest of casein	4 g
Beef extract	1.5 g
Yeast extract	3 g
Glucose monohydrate	1 g
Agar	15 g
Water to produce	1000 ml

Medium B

Pancreatic digest of casein	17 g
Papaic digest of soya bean	3 g
Sodium chloride	5 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate	2.5 g
Agar	15 g
Polysorbate 80	10 g
Water to produce	1000 ml

The polysorbate 80 is added to the hot solution of the other ingredients after boiling, and immediately before adjusting to volume.

Medium C

Peptone	6 g
Beef extract	1.5 g
Yeast extract	3 g
Sodium chloride	3.5 g
Glucose monohydrate	1 g
Dipotassium hydrogen phosphate	3.68 g
Potassium dihydrogen phosphate	1.32 g
Water to produce	1000 ml

Medium D

Heart extract	1.5 g
Yeast extract	1.5 g
Peptone-casein	5 g
Glucose monohydrate	1 g
Sodium chloride	3.5 g
Dipotassium hydrogen phosphate	3.68 g
Potassium dihydrogen phosphate	1.32 g
Potassium nitrate	2 g
Water to produce	1000 ml

Medium E

Peptone	5 g
Meat extract	3 g
Disodium hydrogen phosphate,12H_2O	26.9 g
Agar	10 g
Water to produce	1000 ml

The disodium hydrogen phosphate is added as a sterile solution after sterilisation of the medium.

Medium F

Peptone	9.4 g
Yeast extract	4.7 g
Beef extract	2.4 g
Sodium chloride	10.0 g
Glucose monohydrate	10.0 g
Agar	23.5 g
Water to produce	1000 ml

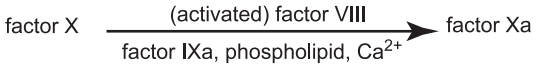
Medium G

Glycerol	10 g
Peptone	10 g
Meat extract	10 g
Sodium chloride	3 g
Agar	15 g
Water to produce	1000 ml

pH 7.0 ± 0.1 after sterilisation.

01/2008:20704

2.7.4. ASSAY OF HUMAN COAGULATION FACTOR VIII



Human coagulation factor VIII is assayed by its biological activity as a cofactor in the activation of factor X by activated factor IX (factor IXa) in the presence of calcium ions and phospholipid. The potency of a factor VIII preparation is estimated by comparing the quantity necessary to achieve a certain rate of factor Xa formation in a test mixture containing the substances that take part in the activation of factor X, and the quantity of the International Standard, or of a reference preparation calibrated in International Units, required to produce the same rate of factor Xa formation.

The International Unit is the factor VIII activity of a stated amount of the International Standard, which consists of a freeze-dried human coagulation factor VIII concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Human coagulation factor VIII BRP is calibrated in International Units by comparison with the International Standard.

The chromogenic assay method consists of 2 consecutive steps: the factor VIII-dependent activation of factor X in a coagulation-factor reagent composed of purified components, and the enzymatic cleavage of a chromogenic factor Xa substrate to yield a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between the rate of factor Xa formation and the factor VIII concentration. The assay is summarised by the following scheme.

Step 1

Step 2

Both steps employ reagents that may be obtained commercially from a variety of sources. Although the composition of individual reagents may be subject to some variation, their essential features are described in the following specification. Deviations from this description may be permissible provided that it has been shown, using the International Standard for human blood coagulation factor VIII concentrate as the standard, that the results obtained do not differ significantly.

It is important to demonstrate by validation the suitability of the kit used, notably by checking the time course of factor Xa generation in order to determine the time taken to reach 50 per cent of the maximal factor Xa generation.

REAGENTS

The coagulation factor reagent comprises purified proteins derived from human or bovine sources. These include factor X, factor IXa, and a factor VIII activator, usually thrombin. These proteins are partly purified, preferably to at least 50 per cent, and do not contain impurities that interfere with the activation of factor VIII or factor X. Thrombin may be present in its precursor form prothrombin, provided that its activation in the reagent is sufficiently rapid to give almost instantaneous activation of factor VIII in the assay. Phospholipid may be obtained from natural sources or be synthetically prepared, and must, to a substantial extent, consist of the species phosphatidylserine. The components of the complete reagent are usually divided into at least 2 separate reagents, each lacking the ability to generate factor Xa on its own. One of the reagents contains calcium ions. After reconstitution, the reagents may be combined provided that no substantial amounts of factor Xa are generated in the absence of factor VIII. In the final incubation mixture, factor VIII must be the only rate-limiting component.

The 2nd step comprises the quantification of the formed factor Xa, employing a chromogenic substrate that is specific for factor Xa. Generally this consists of a derivatised short peptide of between 3 and 5 amino acids, joined to a chromophore group. On cleavage of this group from the peptide substrate, its chromophoric properties shift to a wavelength allowing its spectrophotometric quantification. The substrate must also contain appropriate inhibitors to stop further factor Xa generation, e.g. chelating agents, and to suppress thrombin activity.

ASSAY PROCEDURE

Reconstitute the entire contents of 1 ampoule of the reference preparation and of the preparation to be examined; use immediately. Add sufficient prediluent to the reconstituted preparations to produce solutions containing 0.5-2.0 IU/ml.

The prediluent consists of haemophilia A plasma, or of an artificially prepared reagent that contains sufficient von Willebrand factor and that gives results that do not differ significantly from those obtained employing haemophilia plasma. The prediluted materials must be stable beyond the time required for the assay.

Prepare further dilutions of the reference and test preparations using a non-chelating, appropriately buffered solution, for example, tris(hydroxymethyl)aminomethane or imidazole, containing 1 per cent of human or bovine albumin. Prepare at least 2 dilution series of at least 3 further dilutions for each material. Prepare the dilutions such that the final factor VIII concentration in the reaction mixture is preferably below 0.01 IU/ml, during the step of factor Xa generation.

Prepare a control solution that includes all components except factor VIII.

Prepare all dilutions in plastic tubes and use immediately.

Step 1. Mix prewarmed dilutions of the factor VIII reference preparation and of the preparation to be examined with an appropriate volume of the prewarmed coagulation factor reagent or a combination of its separate constituents, and incubate the mixture in plastic tubes or microplate wells at 37 °C. Allow the activation of factor X to proceed for a suitable time, terminating the reaction (step 2) when the factor Xa concentration has reached approximately 50 per cent of the maximal (plateau) level. Appropriate activation times are usually between 2 min and 5 min.

Step 2. Terminate the activation by addition of a prewarmed reagent containing a chromogenic substrate. Quantify the rate of substrate cleavage, which must be linear with the concentration of factor Xa formed, by measuring the absorbance change at an appropriate wavelength using a spectrophotometer, either monitoring the absorbance continuously, thus allowing the initial rate of substrate cleavage to be calculated, or terminating the hydrolysis reaction after a suitable interval by lowering the pH by addition of a suitable reagent, such as a 50 per cent *V/V* solution of acetic acid, or a 1 M pH 3 citrate buffer solution. Adjust the hydrolysis time to achieve a linear development of chromophore over time. Appropriate hydrolysis times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Calculate the potency of the test preparation by the usual statistical methods (for example, *5.3*).

01/2008:20705

2.7.5. ASSAY OF HEPARIN

The anticoagulant activity of heparin is determined *in vitro* by comparing its ability in given conditions to delay the clotting of recalcified citrated sheep plasma with the same ability of a reference preparation of heparin calibrated in International Units.

The International Unit is the activity contained in a stated amount of the International Standard, which consists of a quantity of freeze-dried heparin sodium from pork intestinal mucosa. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Heparin sodium BRP is calibrated in International Units by comparison with the International Standard by means of the assay given below.

Carry out the assay using one of the following methods for determining the onset of clotting and using tubes and other equipment appropriate to the chosen method:

a) direct visual inspection, preferably using indirect illumination and viewing against a matt black background;

b) spectrophotometric recording of the change in optical density at a wavelength of approximately 600 nm;

c) visual detection of the change in fluidity on manual tilting of the tubes;

d) mechanical recording of the change in fluidity on stirring, care being taken to cause the minimum disturbance of the solution during the earliest phase of clotting.

ASSAY PROCEDURE

The volumes in the text are given as examples and may be adapted to the apparatus used provided that the ratios between the different volumes are respected.

Dilute *heparin sodium BRP* with a 9 g/l solution of *sodium chloride R* to contain a precisely known number of International Units per millilitre and prepare a similar solution of the preparation to be examined which is expected to have the same activity. Using a 9 g/l solution of *sodium chloride R*, prepare from each solution a series of dilutions in geometric progression such that the clotting time obtained with the lowest concentration is not less than 1.5 times the blank recalcification time, and that obtained with the highest concentration is such as to give a satisfactory log dose-response curve, as determined in a preliminary test.

Place 12 tubes in a bath of iced water, labelling them in duplicate: T_1, T_2 and T_3 for the dilutions of the preparation to be examined and S_1, S_2 and S_3 for the dilutions of the reference preparation. To each tube add 1.0 ml of thawed *plasma substrate R1* and 1.0 ml of the appropriate dilution of the preparation to be examined or the reference preparation. After each addition, mix but do not allow bubbles to form. Treating the tubes in the order S_1, S_2, S_3, T_1, T_2, T_3, transfer each tube to a water-bath at 37 °C, allow to equilibrate at 37 °C for about 15 min and add to each tube 1 ml of a suitable APTT (Activated Partial Thromboplastin Time) reagent containing phospholipid and a contact activator, at a dilution giving a suitable blank recalcification time not exceeding 60 s. After exactly 2 min add 1 ml of a 3.7 g/l solution of *calcium chloride R* previously heated to 37 °C and record as the clotting time the interval in seconds between this last addition and the onset of clotting determined by the chosen technique. Determine the blank recalcification time at the beginning and at the end of the procedure in a similar manner, using 1 ml of a 9 g/l solution of *sodium chloride R* in place of one of the heparin dilutions; the 2 blank values obtained should not differ significantly. Transform the clotting times to logarithms, using the mean value for the duplicate tubes. Repeat the procedure using fresh dilutions and carrying out the incubation in the order T_1, T_2, T_3, S_1, S_2, S_3. Calculate the results by the usual statistical methods (*5.3*).

Carry out not fewer than 3 independent assays. For each such assay prepare fresh solutions of the reference preparation and the preparation to be examined and use another, freshly thawed portion of plasma substrate.

Calculate the potency of the preparation to be examined, combining the results of these assays, by the usual statistical methods (*5.3*). When the variance due to differences between assays is significant at $P = 0.01$, a combined estimate of potency may be obtained by calculating the non-weighted mean of potency estimates.

01/2008:20706
corrected 6.0

2.7.6. ASSAY OF DIPHTHERIA VACCINE (ADSORBED)

The potency of diphtheria vaccine is determined by administration of the vaccine to guinea-pigs followed either by challenge with diphtheria toxin (method A or B) or by determination of the titre of antibodies against diphtheria toxin or toxoid in the serum of guinea-pigs (method C). In both cases, the potency of the vaccine is calculated by comparison with a reference preparation, calibrated in International Units.

The International Unit is the activity contained in a stated amount of the International Standard, which consists of a quantity of diphtheria toxoid adsorbed on aluminium

hydroxide. The equivalence in International Units of the International Standard is stated by the World Health Organisation (WHO).

Diphtheria vaccine (adsorbed) BRP is suitable for use as a reference preparation.

The method chosen for the assay of diphtheria vaccine (adsorbed) depends on the intended purpose. Method A or B is used:

1. during development of a vaccine, to assay batches produced to validate the production;
2. wherever revalidation is needed following a significant change in the manufacturing process.

Method A or B may also be used for the routine assay of batches of vaccine, but in the interests of animal welfare, method C is used wherever possible.

Method C may be used, except as specified under 1 and 2 above, after verification of the suitability of the method for the product. For this purpose, a suitable number of batches (usually 3) are assayed by method C and method A or B. Where different vaccines (monovalent or combinations) are prepared from diphtheria toxoid of the same origin, and with comparable levels (expressed in Lf/ml) of the same diphtheria toxoid, suitability demonstrated for the combination with the highest number of components can be assumed to be valid for combinations with fewer components and for monovalent vaccines. Any combinations containing a whole-cell pertussis component or containing haemophilus type b conjugate vaccine with diphtheria toxoid or CRM 197 diphtheria protein as carrier in the same vial must always be assessed separately.

For combinations containing diphtheria and tetanus components, the serological assay (method C) can be performed with the same group of animals used for the serological assay of the tetanus vaccine (adsorbed) (*2.7.8*) when the common immunisation conditions for the diphtheria and the tetanus components (for example, doses, duration) have been demonstrated to be valid for the combined vaccine.

The design of the assays described below uses multiple dilutions for the test and reference preparations. Once the analyst has sufficient experience with this method for a given vaccine, it is possible to apply a simplified model such as a single dilution for both test and reference preparations. Such a model enables the analyst to determine whether the potency of the test preparation is significantly higher than the minimum required, but does not give information on linearity, parallelism and the dose-response curve. The simplified model allows for a considerable reduction in the number of animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the protection of vertebrate animals used for experimental and other scientific purposes.

Where a single-dilution assay is used, production and test consistency over time are monitored via suitable indicators and by carrying out a full multiple-dilution assay periodically, for example every 2 years. For serological assays, suitable indicators to monitor test consistency are:

- the mean and standard deviation of relative antitoxin titres or scores of the serum samples obtained after administration of a fixed dose of the vaccine reference preparation;
- the antitoxin titres or scores of run controls (positive and negative serum samples);
- the ratio of antitoxin titres or scores for the positive serum control to the serum samples corresponding to the reference vaccine.

METHOD A: INTRADERMAL CHALLENGE TEST IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy, white guinea-pigs from the same stock and of a size suitable for the prescribed number of challenge sites, the difference in body mass between the heaviest and the lightest animal being not greater than 100 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 5 guinea-pigs as unvaccinated controls.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of diphtheria toxin containing 67 to 133 lr/100 in 1 Lf and 25 000 to 50 000 minimal reacting doses for guinea-pig skin in 1 Lf. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the activity for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent to obtain a challenge toxin solution containing about 0.0512 Lf in 0.2 ml. Prepare from this a further series of 5 four-fold dilutions containing about 0.0128, 0.0032, 0.0008, 0.0002 and 0.00005 Lf in 0.2 ml.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 ml per guinea-pig, will result in an intradermal score of approximately 3 when the animals are challenged.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of guinea-pigs, and inject subcutaneously 1.0 ml of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, shave both flanks of each guinea-pig and inject 0.2 ml of each of the 6 toxin dilutions intradermally into 6 separate sites on each of the vaccinated guinea-pigs in such a way as to minimise interference between adjacent sites.

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, inject the unvaccinated control animals with dilutions containing 80, 40, 20, 10 and 5×10^{-6} Lf of the challenge toxin.

READING AND INTERPRETATION OF RESULTS

Examine all injection sites 48 h after injection of the challenge toxin and record the incidence of specific diphtheria erythema. Record also the number of sites free from such reactions as the intra-dermal challenge score. Tabulate the intradermal challenge scores for all the animals receiving the same dilution of vaccine and use those data with a suitable transformation, such as $(\text{score})^2$ or $\arcsin((\text{score}/6)^2)$, to obtain an estimate of the relative potency for each of the test preparations by parallel-line quantitative analysis.

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the mean score obtained at the lowest dose level is less than 3 and the mean score at the highest dose level is more than 3;
- where applicable, the toxin dilution that contains 40×10^{-6} Lf gives a positive erythema in at least 80 per cent of the control guinea-pigs and the dilution containing 20×10^{-6} Lf gives a positive erythema in less than 80 per cent of the guinea-pigs (if these criteria are not met a different toxin has to be selected);
- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows no deviation from linearity and parallelism.

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD B: LETHAL CHALLENGE TEST IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 4 further groups of 5 guinea-pigs as unvaccinated controls.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of diphtheria toxin containing not less than 100 LD_{50} per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the lethal dose for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent to obtain a challenge toxin solution containing approximately 100 LD_{50} per millilitre. If necessary, use portions of the challenge toxin solution diluted 1 to 32, 1 to 100 and 1 to 320 with the same diluent.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 ml per guinea-pig, protect approximately 50 per cent of the animals from the lethal effects of the subcutaneous injection of the quantity of diphtheria toxin prescribed for this test.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of guinea-pigs, and inject subcutaneously 1.0 ml of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 1.0 ml of the challenge toxin solution (100 LD_{50}).

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, allocate the challenge toxin solution and the 3 dilutions made from it, 1 to each of the 4 groups of 5 guinea-pigs, and inject subcutaneously 1.0 ml of each solution into each guinea-pig in the group to which that solution is allocated.

READING AND INTERPRETATION OF RESULTS

Count the number of surviving guinea-pigs 4 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of animals surviving in each of the groups of vaccinated guinea-pigs, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the guinea-pigs;
- where applicable, the number of animals that die in the 4 groups of 5 injected with the challenge toxin solution and its 3 dilutions indicates that the challenge dose was approximately 100 LD_{50};
- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows no deviation from linearity and parallelism.

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. Use a further group of non-vaccinated guinea-pigs of the same origin to provide a negative serum control. If test consistency has been demonstrated, a reference negative serum control may be used.

REFERENCE PREPARATION

Use a suitable reference preparation such as *diphtheria vaccine (adsorbed) BRP* or a batch of vaccine shown to be effective in clinical studies, or a batch representative thereof, and which has been calibrated in International Units with reference to *diphtheria vaccine (adsorbed) BRP* or the International Standard for diphtheria toxoid (adsorbed).

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R* as diluent, prepare serial dilutions of the vaccine to be examined and the reference preparation; series differing by 2.5- to 5-fold steps have been found to be suitable. Use not fewer than 3 dilutions within the range of, for example, 0.5-16 IU/ml for the reference vaccine and within the range of, for example, 1:2 to 1:125 for the vaccine to be examined. Use the dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

IMMUNISATION

Inject subcutaneously to each guinea-pig 1.0 ml of the dilution allocated to its group.

BLOOD SAMPLING

35-42 days after immunisation, take a blood sample from each vaccinated and control guinea-pig using a suitable method.

PREPARATION OF SERUM SAMPLES

Avoid frequent freezing and thawing of serum samples. To avoid microbial contamination, it is preferable to carry out manipulations in a laminar-flow cabinet.

DETERMINATION OF ANTIBODY TITRE

Determine the relative antibody titre or score of each serum sample by a suitable immunochemical method (*2.7.1*). The methods shown below (enzyme-linked immunosorbent assay (ELISA) and Vero cell assay) have been found to be suitable.

CALCULATION OF POTENCY

Calculate the potency of the vaccine to be examined in International Units relative to the reference preparation, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- the confidence limits (P = 0.95) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

The following section is published for information.

Assay of diphtheria vaccine (adsorbed): guidelines

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

PREPARATION OF SERUM SAMPLES

For the preparation of serum samples, the following technique has been found to be suitable. Invert the tubes containing blood samples 6 times and allow to stand at 37 °C for 2 h, then at 4 °C for 2 h. Centrifuge at room temperature at 800 *g* for 20 min. Transfer the serum to sterile tubes and store at a temperature below – 20 °C. At least a 40 per cent yield of serum is obtained by this procedure.

DETERMINATION OF ANTIBODY TITRE

The ELISA and Vero cell assays shown below are given as examples of immunochemical methods that have been found to be suitable for the determination of antibody titre.

Determination of antibody titre in guinea-pig serum by enzyme-linked immunosorbent assay (ELISA). Dilutions of test and reference sera are made on ELISA plates coated with diphtheria toxoid. A positive guinea-pig serum control and a negative guinea-pig serum control are included on each plate to monitor the assay performance. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig-IgG is added, followed by a peroxidase substrate. Optical density is measured and the relative antibody titre is calculated using the usual statistical methods (for example, *5.3*).

Reagents and equipment

- *ELISA plates*: 96 wells, columns 1-12, rows A-H.
- *Diphtheria guinea-pig antiserum (for vaccines-human use)* (positive control serum), obtained by immunisation of guinea-pigs using *diphtheria vaccine (adsorbed) BRP*.
- *Peroxidase conjugate*. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.
- *Diphtheria toxoid*.
- *Carbonate coating buffer pH 9.6*. Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 ml of *water R*. Distribute into 150 ml bottles and sterilise by autoclaving at 121 °C for 15 min.
- *Phosphate-buffered saline pH 7.4 (PBS)*. Dissolve with stirring 80.0 g of *sodium chloride R*, 2.0 g of *potassium dihydrogen phosphate R*, 14.3 g of *disodium hydrogen phosphate dihydrate R* and 2.0 g of *potassium chloride R* in 1000 ml of *water R*. Store at room temperature to prevent crystallisation. Dilute to 10 times its volume with *water R* before use.
- *Citric acid solution*. Dissolve 10.51 g of *citric acid R* in 1000 ml of *water R* and adjust the solution to pH 4.0 with a 400 g/l solution of *sodium hydroxide R*.
- *Washing buffer*. PBS containing 0.5 g/l of *polysorbate 20 R*.
- *Diluent blocking buffer*. PBS containing 0.5 g/l of *polysorbate 20 R* and 25 g/l of dried skimmed milk.
- *Peroxidase substrate*. Shortly before use, dissolve 10 mg of *diammonium 2,2'-azinobis(3-ethylbenzothiazoline-6-sulphonate) R* (ABTS) in 20 ml of citric acid solution. Immediately before use add 5 µl of *strong hydrogen peroxide solution R*.

Method

The description below is given as an example of a suitable plate layout but others may be used. Wells 1A-H are for negative control serum and wells 2A-H and 12A-H are for positive control serum for assay monitoring. Wells 3-11A-H are for test samples.

Coat each well of the ELISA plates with 100 µl of diphtheria toxoid solution (0.5 Lf/ml in carbonate coating buffer pH 9.6). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid temperature gradient effects, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with washing buffer. Block the plates by addition of 100 µl of diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing buffer. Place 100 µl of diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of negative control serum, positive control serum (from about 0.01 IU/ml) and test sera. Allocate the negative control serum to column 1, positive control serum to columns 2 and 12 and test sera to columns 3-11 and add 100 µl of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make twofold serial dilutions from row B, down the plate to row H, by transferring 100 µl from one well to the next well. Discard 100 µl from the last row so that all wells contain 100 µl. Incubate at 37 °C for 2 h. Wash thoroughly with washing buffer. Prepare a suitable dilution (a 2000-fold dilution has been found to be suitable) of peroxidase conjugate in diluent block buffer and add 100 µl to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing buffer. Add 100 µl of peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as addition of substrate was made.

Determination of antibody titre in guinea-pig serum by Vero cell assay. The method used relies either on metabolic inhibition (method 1) or on cytotoxicity (method 2) as the end point, and on either microscopic (cell morphology) or visual (colour) inspection of the cells.

The limit of detection is specific for each antitoxin and is usually between 0.015 IU/ml (method 1) and 0.05 IU/ml (method 2).

The endpoint is taken as the highest serum dilution protecting cells from the diphtheria toxin effect. The antitoxin activity is calculated with respect to guinea-pig or WHO reference standard, and expressed in International Units per millilitre.

Reagents and equipment

- *Flat-bottomed tissue culture plates*: 96 wells, columns 1-12, rows A-H.
- *75 cm^2 tissue culture flasks.*
- *Diphtheria toxin.*
- *Diphtheria guinea-pig antiserum (for vaccines-human use)* (positive control serum), obtained by immunisation of guinea-pigs with *diphtheria vaccine (adsorbed) BRP.*
- *Vero cells* (African Green Monkey kidney cells). Cell passages from P2 to P15 are suitable for use.

Method 1. The diphtheria toxin causes a cytopathogenic effect on Vero cells leading to cellular lysis. Antibodies directed against diphtheria toxin may inhibit this cytopathogenic effect. Consequently, the potency of a diphtheria vaccine may be indirectly determined with the help of this cell culture system if different serum dilutions from immunised animals are cultured with a constant toxin concentration. In the Vero cell assay, yellow colour indicates viable cells, red colour dead cells. When only part of the cells are dead, the colour may be orange.

Reagents and equipment

- *Modified MEM.* Minimum Essential Medium (MEM) with Earle's Salts, without L-glutamine and sodium bicarbonate.
- *Modified medium 199.* Medium 199, with Hanks' Solution and L-glutamine, without sodium bicarbonate.
- *Foetal bovine serum.*
- *Sodium bicarbonate 7.5 per cent solution.*
- *Trypsin solution:* trypsin 2.5 per cent solution.
- *EDTA solution:* EDTA 0.02 per cent (Versene 1:5000) solution.
- *Modified D-PBS.* Dulbecco's phosphate buffered saline (D-PBS), without calcium, or magnesium.
- *L-glutamine 200mM solution.*
- *Penicillin/streptomycin solution.*
- *Primary culture medium.* To 50 ml of modified MEM add 440 ml of *water R*, 5 ml of L-glutamine 200 mM solution, and 10 ml of sodium bicarbonate 7.5 per cent solution. To 25 ml of this medium add 1.25 ml of foetal bovine serum.
- *Maintenance culture medium.* Similar to the primary culture medium except that 0.5 ml instead of 1.25 ml of foetal bovine serum is added to 20 ml of the enriched MEM medium.
- *Medium A.* To 50.0 ml of modified medium 199 add 440.0 ml of *water R*, 5.0 ml of L-glutamine 200 mM solution and 10.0 ml of sodium bicarbonate 7.5 per cent solution.
- *Medium B.* To 150.0 ml of medium A add 3.0 ml of foetal bovine serum and 0.3 ml of penicillin/streptomycin solution.
- *Medium C.* To 22.0 ml of medium A add 0.44 ml of foetal bovine serum and 0.44 ml of penicillin/streptomycin solution.

Vero cells are cultured in tissue culture flasks (for example 75 cm^2/250 ml) in an incubator at 36 ± 1 °C, 5 per cent CO_2 and 90 per cent relative humidity. Vero cells are first grown in the primary culture medium. After 2-3 days of growth, the primary culture medium is replaced by the maintenance culture medium. When a confluent monolayer is obtained, the culture supernatant is discarded and the cell layer washed gently with modified D-PBS. Add a mixture of 1 volume of trypsin solution and 1 volume of EDTA solution to the flask. Swirl the flask gently and incubate in the CO_2 incubator for about 3 min until the cells start to break from the monolayer. Vigorously tap the side of the flask to make the cells fall. Resuspend the cells in 5-6 ml of fresh medium C to obtain a homogeneous suspension. Prepare a cell suspension in medium C containing approximately 1×10^5 cells/ml.

Place 25 µl of medium B in each well except those of column 1. Place 25 µl of the diphtheria guinea-pig antiserum (for vaccines-human use) (positive control serum, working dilution in medium B of 0.40 IU/ml) in wells A1, A2 and A11. Place 25 µl of guinea-pig serum samples in wells B-G of columns 1, 2 and 11. Place 25 µl of negative control serum in row H of columns 1, 2 and 11. Using a multichannel micropipette, make twofold serial dilutions across the plate (from column 2 up to column 10 for rows A-G and up to column 8 for row H). Discard 25 µl from the wells in column 10 in rows A-G, and from well H8.

Reconstitute the diphtheria toxin with saline solution to give a solution of 50 IU/ml. Prepare a 50-fold dilution of this diphtheria toxin dilution in medium B to obtain a working solution of 1.0 IU/ml. Add 25 µl of this working solution to wells A12 and B12 (toxin control). Make twofold serial dilutions by tranferring 25 µl from one well to the next, from well B12 down to H12. Change the tip between each dilution. Discard 25 µl from well H12. Add 25 µl of medium B to wells B12-H12. Then, place 25 µl of the working dilution of the diphtheria toxin (1.0 IU/ml) in each well of rows A-H, from column 1-10, except in wells H9 and H10 (cells only, without serum and without toxin).

Cover the plates with lids or sealer and shake gently. Incubate the plates for at least 2 h in a humid container in a CO_2 incubator at 37 °C. Add 200 µl of cell suspension containing 1 x 10^5 cells/ml to all the wells. Cover the plates with sealer. Incubate at 37 °C for 5 days. Check for microbial contamination by microscopic examination.

Yellow wells are recorded as negative and red wells indicate dead cells and are recorded as positive. A colour between yellow and red indicates a mixture of viable and dead cells and is recorded as positive/negative. The results based on the change in colour can be confirmed by reading viable and dead cells under the microscope.

The potency of the guinea-pig antiserum samples is obtained by comparing the last well of the standard preparation showing complete neutralisation of the toxin, with the last well of the sample demonstrating the same effect. For calculations of potency, it must be remembered that the endpoint may be between a negative well and a positive/negative well.

Method 2: Thiazolyl blue MTT is reduced to a blue/black formazan product by the mitochondrial dehydrogenase of viable cells, and thus serves as a quantitative measure of living cells present, indicating when the toxin has been neutralised by the antitoxin. White or colourless wells indicate absence of viable cells due to insufficient antitoxin to neutralise the toxin.

Reagents and equipment

- *MEM* (Minimal Essential Media).
- *Newborn calf serum.*
- *Antibiotic solution* (containing 10 000 units of penicillin, 10 mg of streptomycin and 25 µg of amphotericin B per millilitre).
- *L-glutamine 200mM solution.*
- *Trypsin-EDTA.*
- *Thiazolyl blue MTT* [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide].
- *1 M HEPES buffer pH 8.1.* Dissolve 18.75 g of HEPES in 82.5 ml of *water R* and 30.0 ml of *2 M sodium hydroxide R.*
- *Glucose solution (10 per cent).*
- *Complete culture medium.* Mix 200 ml of MEM with 10 ml of newborn calf serum, 3.0 ml of 1 M HEPES buffer pH 8.1, 2.0 ml of glucose solution (10 per cent), 2.0 ml of antibiotic solution and 2.0 ml of L-glutamine 200mM solution.
- *Phosphate-buffered saline pH 7.4 (PBS).* Dissolve 10.0 g of *sodium chloride R,* 0.75 g of *potassium chloride R,* 1.44 g of *disodium hydrogen phosphate R,* and 0.125 g of *potassium dihydrogen phosphate R* in *water R,* and dilute to 1000.0 ml with the same solvent. Adjust the pH (*2.2.3*) if necessary. Autoclave at 120 °C for 15 min.
- *Thiazolyl blue MTT solution.* Dissolve 0.1 g of thiazolyl blue MTT in 20 ml of PBS. Sterilise by filtration (0.2 µm) and store in dark bottle.
- *pH adjuster solution.* Mix 40 ml of *acetic acid R* with 1.25 ml of *1 M hydrochloric acid* and 8.75 ml of *water R.*
- *Extraction buffer pH 4.7.* Dissolve 10 g of *sodium laurilsulfate R* in *water R* and add 50 ml of *dimethylformamide R,* and dilute to 100 ml with *water R.* Adjust the pH (*2.2.3*) with an appropriate volume of pH adjuster solution.

Vero cells are cultured in tissue culture flasks (for example 75 cm^2/250 ml) in an incubator at 36 ± 1 °C, 5 per cent CO_2 and 90 per cent relative humidity. Vero cells are grown in the complete culture medium. After 6-7 days of growth, a confluent monolayer is obtained, the culture supernatant is discarded and the cell layer is washed 3 times with trypsin-EDTA: gently pipette out the medium, add 0.5-1 ml of trypsin-EDTA, swirl the flask and tip the trypsin out. Do this twice, and the 3rd time, place the flask in the incubator for 5 min until the cells start to break from the monolayer. Vigorously tap the side of the flask to make the cells fall. Resuspend the cells in 6-25 ml of fresh complete culture medium to obtain a homogeneous suspension. Prepare a cell suspension in complete culture medium containing approximately 4×10^5 cells/ml.

Place 50 µl of complete culture medium in each well except those of column 1. Place 100 µl of diphtheria guinea pig antiserum (for vaccines-human use) (positive control serum, working dilution in complete culture medium of 0.12 IU/ml) in well A1 and 50 µl in well A11. Place 100 µl of guinea pig test serum samples, diluted if necessary, in wells B1-G1. Add 50 µl of the same sample to wells B11-G11 in the corresponding row. Place 100 µl of negative control serum in well H1 and 50 µl in well H11. Using a multi-channel micropipette, make twofold serial dilutions by transferring 50 µl from one well to the next working across the plate (from column 1-10 for rows A-G and from column 1-8 for row H).

Diphtheria toxin of known activity and Lf content is diluted to a suitable working stock containing at least 4 minimum cytopathic doses in complete culture medium. Add 50 µl of the diluted toxin to each well except H9 and H10 (cell control), A11-H11 (serum control) and A12-H12 (toxin control). Add 100 µl of diluted toxin to well A12 and make twofold serial dilutions by transferring 50 µl from one well to the next working down the plate (from well A12-H12). Discard 50 µl from well H12. Add 50 µl of complete medium to wells H9 and H10.

Cover the plates with a lid or sealer and leave for 1 h at room temperature to allow toxin neutralisation to occur. 50 µl of cell suspension containing approximately 4×10^5 cells/ml is added to each well. The plates are sealed and incubated at 37 °C for 6 days. Check for microbial contamination by microscopic examination. 10 µl of thyazolyl blue MTT solution is added to each well. The plates are incubated at 37 °C for a further 2-4 h. Then, the medium is removed and 100 µl of extraction buffer pH 4.7 is added to each well. The plates are incubated at 37 °C and left overnight to aid the extraction process. Once extraction and solubilisation is complete, plates are visually examined or read at 570 nm.

Blue/black wells are recorded as negative (all the cells are alive, toxin neutralisation by antitoxin) and white or colourless wells indicate dead cells (no toxin neutralisation) and are recorded as positive.

The potency of the test antitoxin is obtained by comparing the last well of the reference antitoxin preparation showing neutralisation of the toxin, with the last well of the antitoxin preparation demonstrating the same effect. The neutralising antibody titre of the sample being examined can be calculated by multiplication of the dilution factor with total number of International Units per millilitre of the reference preparation at the end point. The test is valid if all the cells in the toxin control are dead and reference antitoxin gives a neutralisation in at least the first 2 dilutions tested.

01/2008:20707

2.7.7. ASSAY OF PERTUSSIS VACCINE

The potency of pertussis vaccine is determined by comparing the dose necessary to protect mice against the effects of a lethal dose of *Bordetella pertussis,* administered intracerebrally, with the quantity of a reference preparation, calibrated in International Units, needed to give the same protection.

The International Unit is the activity contained in a stated amount of the International Standard which consists of a quantity of dried pertussis vaccine. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection and distribution of the test animals. Use in the test, healthy mice less than 5 weeks old of a suitable strain from the same stock, the difference in mass between the heaviest and the lightest being not greater than 5 g. Distribute the mice in 6 groups of not fewer than 16 and 4 groups of 10. The mice must all be of the same sex or the males and females should be distributed equally between the groups.

Selection of the challenge strain and preparation of the challenge suspension. Select a suitable strain of *B. pertussis* capable of causing the death of mice within 14 days of intracerebral injection. If more than 20 per cent of the mice die within 48 h of the injection the strain is not suitable. Make one subculture from the strain and suspend the harvested *B. pertussis* in a solution containing 10 g/l of *casein hydrolysate R* and 6 g/l of *sodium chloride R* and having a pH of 7.0 to 7.2 or in another suitable solution. Determine the opacity of the suspension. Prepare a series of dilutions in the same solution and allocate each dilution to a group of ten mice. Inject intracerebrally into each mouse

a dose (0.02 ml or 0.03 ml) of the dilution allocated to its group. After 14 days, count the number of mice surviving in each group. From the results, calculate the expected opacity of a suspension containing 100 LD_{50} in each challenge dose. For the test of the vaccine to be examined make a fresh subculture from the same strain of *B. pertussis* and prepare a suspension of the harvested organisms with an opacity corresponding to about 100 LD_{50} in each challenge dose. Prepare 3 dilutions of the challenge suspension.

Determination of potency. Prepare 3 serial dilutions of the vaccine to be examined and 3 similar dilutions of the reference preparation such that in each the intermediate dilution may be expected to protect about 50 per cent of the mice from the lethal effects of the challenge dose of *B. pertussis*. Suggested doses are 1/8, 1/40 and 1/200 of the human dose of the vaccine to be examined and 0.5 IU, 0.1 IU and 0.02 IU of the reference preparation, each dose being contained in a volume not exceeding 0.5 ml. Allocate 6 dilutions one to each of the groups of not fewer than 16 mice and inject intraperitoneally into each mouse one dose of the dilution allocated to its group. After 14 to 17 days inject intracerebrally into each animal in the groups of not fewer than 16, one dose of the challenge suspension. Allocate the challenge suspension and the 3 dilutions made from it one to each of the groups of 10 mice and inject intracerebrally one dose of each suspension into each mouse in the group to which that suspension is allocated. Exclude from consideration any mice that die within 48 h of challenge. Count the number of mice surviving in each of the groups after 14 days. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the numbers of animals surviving in each of the groups of not fewer than 16.

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and the smallest doses given to the mice;
- the number of animals which die in the four groups of ten injected with the challenge suspension and its dilutions indicates that the challenge dose is approximately 100 LD_{50};
- and the statistical analysis shows no deviation from linearity or parallelism.

The test may be repeated but when more than one test is performed the results of all valid tests must be combined.

01/2008:20708
corrected 6.0

2.7.8. ASSAY OF TETANUS VACCINE (ADSORBED)

The potency of tetanus vaccine is determined by administration of the vaccine to animals (guinea-pigs or mice) followed either by challenge with tetanus toxin (method A or B) or by determination of the titre of antibodies against tetanus toxoid in the serum of the guinea-pigs (method C). In both cases, the potency of the vaccine is calculated by comparison with a reference vaccine, calibrated in International Units. For methods A and B, in countries where the paralysis method is not obligatory, the LD_{50} method may be used. For the LD_{50} method, the number of animals and the procedure are identical to those described for the paralysis method, but the end-point is the death of the animal rather than paralysis.

The International Unit is the activity contained in a stated amount of the International Standard for tetanus toxoid (adsorbed). The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Tetanus vaccine (adsorbed) BRP is calibrated in International Units with reference to the International Standard.

The method chosen for the assay of tetanus vaccine (adsorbed) depends on the intended purpose. Method A or B is used:

1. during development of a vaccine, to assay batches produced to validate the production;
2. wherever revalidation is needed following a significant change in the manufacturing process.

Method A or B may also be used for the routine assay of batches of vaccine, but in the interests of animal welfare, method C is used wherever possible.

Method C may be used, except as specified under 1 and 2 above, after verification of the suitability of the method for the product. For this purpose, a suitable number of batches (usually 3) are assayed by method C and method A or B. Where different vaccines (monovalent or combinations) are prepared from tetanus toxoid of the same origin and with comparable levels (expressed in Lf/ml) of the same tetanus toxoid, suitability demonstrated for the combination with the highest number of components can be assumed to be valid for combinations with fewer components and for monovalent vaccines. Any combinations containing a whole-cell pertussis component or containing haemophilus type b conjugate vaccine with tetanus toxoid in the same vial must always be assessed separately.

For combinations containing diphtheria and tetanus components, the serological assay (method C) can be performed with the same group of animals used for the serological assay of the diphtheria vaccine (adsorbed) (*2.7.6*) when the common immunisation conditions for the tetanus and the diphtheria components (for example, doses, duration) have been demonstrated to be valid for the combined vaccine.

The design of the assays described below uses multiple dilutions for the test and reference preparations. Based on the potency data obtained in multiple-dilution assays, it may be possible to reduce the number of animals needed to obtain a statistically significant result by applying a simplified model such as a single dilution for both test and reference preparations. Such a model enables the analyst to determine whether the potency of the test preparation is significantly higher than the minimum required, but does not give information on the dose-response curves and their linearity, parallelism and significant slope. The simplified model allows for a considerable reduction in the number of animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the protection of vertebrate animals used for experimental and other scientific purposes.

Where a single-dilution assay is used, production and test consistency over time are monitored via suitable indicators and by carrying out a full multiple-dilution assay periodically, for example every 2 years. For serological assays, suitable indicators to monitor test consistency are:

- the mean and standard deviation of relative antitoxin titres or scores of the serum samples obtained after administration of a fixed dose of the vaccine reference preparation;
- the antitoxin titres or scores of run controls (positive and negative serum samples);

– the ratio of antitoxin titres or scores for the positive serum control to the serum samples corresponding to the reference vaccine.

METHOD A. CHALLENGE TEST IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the activity of the challenge toxin has to be determined, include 3 further groups of 5 guinea-pigs as unvaccinated controls.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of tetanus toxin containing not less than 50 times the 50 per cent paralytic dose per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the paralytic dose for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent (for example, peptone buffered saline solution pH 7.4) to obtain a stable challenge toxin solution containing approximately 50 times the 50 per cent paralytic dose per millilitre. If necessary, use portions of the challenge toxin solution diluted 1 to 16, 1 to 50 and 1 to 160 with the same diluent to determine the activity of the toxin.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 ml per guinea-pig, protect approximately 50 per cent of the animals from the paralytic effects of the subcutaneous injection of the quantity of tetanus toxin prescribed for this test.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of guinea-pigs, and inject subcutaneously 1.0 ml of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 1.0 ml of the challenge toxin solution (containing 50 times the 50 per cent paralytic dose).

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, allocate the 3 dilutions made from the challenge toxin solution, 1 to each of the 3 groups of 5 guinea-pigs, and inject subcutaneously 1.0 ml of each solution into each guinea-pig in the group to which that solution is allocated. The activity and stability of the challenge toxin are determined by carrying out a suitable number of determinations of the 50 per cent paralytic dose. It is then not necessary to repeat the determination for each assay.

READING AND INTERPRETATION OF RESULTS

Examine the guinea-pigs twice daily. Remove and euthanise all animals showing definite signs of tetanus paralysis. Count the number of guinea-pigs without paralysis 5 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of challenged animals without paralysis in each group of vaccinated guinea-pigs, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

– for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the guinea-pigs;
– where applicable, the number of paralysed animals in the 3 groups of 5 injected with the dilutions of the challenge toxin solution indicates that the challenge was approximately 50 times the 50 per cent paralytic dose;
– the confidence limits (P = 0.95) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
– the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD B. CHALLENGE TEST IN MICE

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy mice from the same stock, about 5 weeks old and from a strain shown to be suitable. Use mice of the same sex or with males and females equally distributed between the groups. Distribute the mice in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 3 further groups of not fewer than 5 mice to serve as unvaccinated controls.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of tetanus toxin containing not less than 100 times the 50 per cent paralytic dose per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the paralytic dose for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent (for example, peptone buffered saline solution pH 7.4) to obtain a stable challenge toxin solution containing approximately 50 times the 50 per cent paralytic dose in 0.5 ml. If necessary, use portions of the challenge toxin solution diluted 1 to 16, 1 to 50 and 1 to 160 with the same diluent to determine the activity of the toxin.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 0.5 ml per mouse, protect approximately 50 per cent of the animals from the paralytic effects of the subcutaneous injection of the quantity of tetanus toxin prescribed for this test.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of mice, and inject subcutaneously 0.5 ml of each dilution into each mouse in the group to which that dilution is allocated. After

28 days, inject subcutaneously into each animal 0.5 ml of the challenge toxin solution (containing 50 times the 50 per cent paralytic dose).

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, allocate the 3 dilutions made from the challenge toxin solution, 1 to each of the 3 groups of not fewer than 5 mice, and inject subcutaneously 0.5 ml of each solution into each mouse in the group to which that solution is allocated.

READING AND INTERPRETATION OF RESULTS

Examine the mice twice daily. Remove and euthanise all animals showing definite signs of tetanus paralysis. Count the number of mice without paralysis 4 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of challenged animals without paralysis in each group of vaccinated mice, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the mice;
- where applicable, the number of paralysed animals in the 3 groups of not fewer than 5 injected with the dilutions of the challenge toxin solution, indicates that the challenge dose was approximately 50 times the 50 per cent paralytic dose;
- the confidence limits (P = 0.95) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. Use a further group of non-vaccinated guinea-pigs of the same origin to provide a negative serum control. If test consistency has been demonstrated, a reference negative serum control may be used.

REFERENCE PREPARATION

Use a suitable reference preparation such as *tetanus vaccine (adsorbed) BRP* or a batch of vaccine shown to be effective in clinical studies, or a batch representative thereof, and which has been calibrated in International Units with reference to *tetanus vaccine (adsorbed) BRP* or the International Standard for tetanus toxoid (adsorbed).

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R* as diluent, prepare serial dilutions of the vaccine to be examined and the reference preparation; series differing by 2.5- to 5-fold steps have been found to be suitable. Use not fewer than 3 dilutions within the range of, for example, 0.5-16 IU/ml for each series. Use the dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

IMMUNISATION

Inject subcutaneously to each guinea-pig 1.0 ml of the dilution allocated to its group.

BLOOD SAMPLING

35-42 days after immunisation, take a blood sample from each vaccinated and control guinea-pig using a suitable method.

PREPARATION OF SERUM SAMPLES

Avoid frequent freezing and thawing of serum samples. To avoid microbial contamination, it is preferable to carry out manipulations in a laminar-flow cabinet.

DETERMINATION OF ANTIBODY TITRE

Determine the relative antibody titre or score of each serum sample by a suitable immunochemical method (*2.7.1*). The methods shown below (enzyme-linked immunosorbent assay (ELISA) and toxin-binding inhibition (ToBI)) have been found to be suitable.

CALCULATION OF POTENCY

Calculate the potency of the vaccine to be examined in International Units relative to the reference preparation, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- the confidence limits (P = 0.95) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

The following section is published for information.

Assay of tetanus vaccine (adsorbed): guidelines

METHOD A. CHALLENGE TEST IN GUINEA-PIGS

READING AND INTERPRETATION OF RESULTS

In order to minimise suffering in the test animals, it is recommended to note the degree of paralysis on a scale such as that shown below. The scale gives typical signs when subcutaneous injection of the challenge toxin is made mid-ventrally, directly behind the sternum with the needle pointing towards the neck of the guinea-pig. Grade T3 is taken as the end-point, but with experience grade T2 can be used instead. Tetanus toxin produces in at least 1 of the forelimbs paralysis that can be recognised at an early stage. The tetanus grades in guinea-pigs are characterised by the following signs:

- T1: slight stiffness of 1 forelimb, but difficult to observe;
- T2: paresis of 1 forelimb which still can function;

– T3: paralysis of 1 forelimb. The animal moves reluctantly, the body is often slightly banana-shaped owing to scoliosis;
– T4: the forelimb is completely stiff and the toes are immovable. The muscular contraction of the forelimb is very pronounced and usually scoliosis is observed;
– T5: tetanus seizures, continuous tonic spasm of muscles;
– D: death.

METHOD B. CHALLENGE TEST IN MICE

READING AND INTERPRETATION OF RESULTS

In order to minimise suffering in the test animals, it is recommended to note the degree of paralysis on a scale such as that shown below. The scale gives typical signs when injection of the challenge toxin is made in the dorsal region, close to one of the hind legs. Grade T3 is taken as the end-point, but with experience grade T2 can be used instead. Tetanus toxin produces in the toxin-injected hind leg paresis followed by paralysis that can be recognised at an early stage. The tetanus grades in mice are characterised by the following signs:

– T1: slight stiffness of toxin-injected hind leg, only observed when the mouse is lifted by the tail;
– T2: paresis of the toxin-injected hind leg, which still can function for walking;
– T3: paralysis of the toxin-injected hind leg, which does not function for walking;
– T4: the toxin-injected hind leg is completely stiff with immovable toes;
– T5: tetanus seizures, continuous tonic spasm of muscles;
– D: death.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

PREPARATION OF SERUM SAMPLES

For the preparation of serum samples, the following technique has been found to be suitable. Invert the tubes containing blood samples 6 times and allow to stand at 37 °C for 2 h, then at 4 °C for 2 h. Centrifuge at room temperature at 800 *g* for 20 min. Transfer the serum to sterile tubes and store at a temperature below – 20 °C. At least a 40 per cent yield of serum is obtained by this procedure.

DETERMINATION OF ANTIBODY TITRE

The ELISA and ToBI tests shown below are given as examples of immunochemical methods that have been found to be suitable for the determination of antibody titre.

Determination of antibody titre in guinea-pig serum by enzyme-linked immunosorbent assay (ELISA). Dilutions of test and reference sera are made on ELISA plates coated with tetanus toxoid. A positive guinea-pig serum control and a negative guinea-pig serum control are included on each plate to monitor the assay performance. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig-IgG is added, followed by a peroxidase substrate. Optical density is measured and the relative antibody titre is calculated using the usual statistical methods (for example, *5.3*).

Reagents and equipment

– *ELISA plates*: 96 wells, columns 1-12, rows A-H.
– *Clostridium tetani guinea-pig antiserum (for vaccines-human use) BRP* (positive control serum).
– *Peroxidase conjugate.* Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.
– *Tetanus toxoid.*
– *Carbonate coating buffer pH 9.6.* Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 ml of *water R*. Distribute into 150 ml bottles and sterilise by autoclaving at 121 °C for 15 min.
– *Phosphate-buffered saline pH 7.4 (PBS).* Dissolve with stirring 80.0 g of *sodium chloride R*, 2.0 g of *potassium dihydrogen phosphate R*, 14.3 g of *disodium hydrogen phosphate dihydrate R* and 2.0 g of *potassium chloride R* in 1000 ml of *water R*. Store at room temperature to prevent crystallisation. Dilute to 10 times its volume with *water R* before use.
– *Citric acid solution.* Dissolve 10.51 g of *citric acid R* in 1000 ml of *water R* and adjust the solution to pH 4.0 with a 400 g/l solution of *sodium hydroxide R*.
– *Washing buffer.* PBS containing 0.5 g/l of *polysorbate 20 R*.
– *Diluent block buffer.* PBS containing 0.5 g/l of *polysorbate 20 R* and 25 g/l of dried skimmed milk.
– *Peroxidase substrate.* Shortly before use, dissolve 10 mg of *diammonium 2,2'-azinobis(3-ethylbenzothiazoline-6-sulphonate) R* (ABTS) in 20 ml of citric acid solution. Immediately before use add 5 µl of *strong hydrogen peroxide solution R*.

Method

The description below is given as an example of a suitable plate layout but others may be used. Wells 1A-H are for negative control serum and wells 2A-H and 12A-H are for positive control serum for assay monitoring. Wells 3-11A-H are for test samples.

Coat each well of the ELISA plates with 100 µl of tetanus toxoid solution (0.5 Lf/ml in carbonate coating buffer pH 9.6). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid temperature gradient effects, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with washing buffer. Block the plates by addition of 100 µl of diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing buffer. Place 100 µl of diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of negative control serum, positive control serum (from about 0.01 IU/ml) and test sera. Allocate the negative control serum to column 1, positive control serum to columns 2 and 12 and test sera to columns 3-11 and add 100 µl of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make twofold serial dilutions from row B down the plate to row H, by transferring 100 µl from one well to the next. Discard 100 µl from the last row so that all wells contain 100 µl. Incubate at 37 °C for 2 h. Wash thoroughly with washing buffer. Prepare a suitable dilution (a 2000-fold dilution has been found to be suitable) of peroxidase conjugate in diluent block buffer and add 100 µl to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing buffer. Add 100 µl of peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as addition of substrate was made.

Determination of antibody titre in guinea-pig serum by toxin- or toxoid-binding inhibition (ToBI). Tetanus toxin or toxoid is added to serial dilutions of test and reference sera; the serum/antigen mixtures are incubated overnight. To determine unbound toxin or toxoid, the mixtures are transferred to an ELISA plate coated with tetanus antitoxin. Peroxidase-conjugated equine anti-tetanus IgG is added followed by a peroxidase substrate. Optical density is

measured and the antibody titre is calculated using the usual statistical methods (for example, *5.3*). A positive control serum and a negative control serum are included on each plate to monitor assay performance.

Reagents and equipment

- *Round-bottomed, rigid polystyrene microtitre plates.*
- *Flat-bottomed ELISA plates.*
- *Tetanus toxin or tetanus toxoid.*
- *Clostridium tetani guinea-pig antiserum (for vaccines-human use) BRP* (positive control serum).
- *Equine anti-tetanus IgG.*
- *Peroxidase-conjugated equine anti-tetanus IgG.*
- *Carbonate buffer pH 9.6.* Dissolve 1.5 g of *anhydrous sodium carbonate R*, 2.39 g of *sodium hydrogen carbonate R* and 0.2 g of *sodium azide R* in 1000 ml of *water R*, adjust to pH 9.6 and autoclave at 121 °C for 20 min.
- *Sodium acetate buffer pH 5.5.* Dissolve 90.2 g of *anhydrous sodium acetate R* in 900 ml of *water R*, adjust to pH 5.5 using a saturated solution of *citric acid monohydrate R* and dilute to 1000 ml with *water R*.
- *Phosphate-buffered saline pH 7.2 (PBS).* Dissolve 135.0 g of *sodium chloride R*, 20.55 g of *disodium hydrogen phosphate dihydrate R* and 4.80 g of *sodium dihydrogen phosphate monohydrate R* in *water R* and dilute to 15 litres with the same solvent. Autoclave at 100 °C for 60 min.
- *Diluent buffer.* PBS containing 5 g/l of *bovine albumin R* and 0.5 g/l of *polysorbate 80 R*.
- *Block buffer.* PBS containing 5 g/l of *bovine albumin R*.
- *Tetramethylbenzidine solution.* 6 g/l solution of *tetramethylbenzidine R* in *ethanol (96 per cent) R*. The substance dissolves within 30-40 min at room temperature.
- *Peroxidase substrate.* Mix 90 ml of *water R*, 10 ml of sodium acetate buffer pH 5.5, 1.67 ml of tetramethylbenzidine solution and 20 µl of *strong hydrogen peroxide solution R*.
- *Washing solution.* Tap water containing 0.5 g/l of *polysorbate 80 R*.

Method

Block the microtitre plates by placing in each well 150 µl of block buffer. Cover the plates with a lid or sealer. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing solution. Place 100 µl of PBS in each well. Place 100 µl of reference guinea-pig tetanus antitoxin in the first well of a row. Place 100 µl of undiluted test sera in the first well of the required number of rows. Using a multichannel micropipette, make twofold serial dilutions across the plate (up to column 10), by transferring 100 µl from one well to the next. Discard 100 µl from the last column so that all wells contain 100 µl. Prepare a 0.1 Lf/ml solution of tetanus toxin or toxoid using PBS as diluent. Add 40 µl of this solution to each well except those of column 12. The wells of column 11 are a positive control. Add 40 µl of PBS to the wells of column 12 (negative control). Shake the plates gently and cover them with lids. Coat the ELISA plates: immediately before use make a suitable dilution of equine anti-tetanus IgG in carbonate buffer pH 9.6 and add 100 µl to each well. Incubate the 2 series of plates overnight in a humid atmosphere at 37 °C. To avoid temperature gradient effects, do not stack more than 4 plates high. Cover the plates with lids. On the following day, wash the ELISA plates thoroughly with washing solution. Block the plates by placing in each well 125 µl of block buffer. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing solution. Transfer 100 µl of the pre-incubation mixture from the polystyrene plates to the corresponding wells of the ELISA plates, starting with column 12 and then continuing from 1 to 11. Cover the plates with a lid. Incubate at 37 °C in a humid atmosphere for 2 h. Wash the ELISA plates thoroughly with washing solution. Make a suitable dilution (a 4000-fold dilution has been found to be suitable) of the peroxidase-conjugated equine anti-tetanus IgG in diluent buffer. Add 100 µl of the dilution to each well and cover the plates with a lid. Incubate at 37 °C in a humid atmosphere for 1.5 h. Wash the ELISA plates thoroughly with washing solution. Add 100 µl of peroxidase substrate to each well. A blue colour develops. Incubate the plates at room temperature. Stop the reaction at a given time (within 10 min) by the addition of 100 µl of *2 M sulphuric acid* to each well in the same order as the addition of substrate. The colour changes from blue to yellow. Measure the absorbance at 450 nm immediately after addition of the sulphuric acid or maintain the plates in the dark until reading.

01/2008:20709

2.7.9. TEST FOR Fc FUNCTION OF IMMUNOGLOBULIN

Stabilised human blood. Collect group O human red blood into ACD anticoagulant solution. Store the stabilised blood at 4 °C for not more than 3 weeks.

Phosphate buffered saline pH 7.2. Dissolve 1.022 g of *anhydrous disodium hydrogen phosphate R*, 0.336 g of *anhydrous sodium dihydrogen phosphate R* and 8.766 g of *sodium chloride R* in 800 ml of *water R* and dilute to 1000 ml with the same solvent.

Magnesium and calcium stock solution. Dissolve 1.103 g of *calcium chloride R* and 5.083 g of *magnesium chloride R* in *water R* and dilute to 25 ml with the same solvent.

Barbital buffer stock solution. Dissolve 207.5 g of *sodium chloride R* and 25.48 g of *barbital sodium R* in 4000 ml of *water R* and adjust to pH 7.3 using *1 M hydrochloric acid.* Add 12.5 ml of magnesium and calcium stock solution and dilute to 5000 ml with *water R*. Filter through a membrane filter (pore size 0.22 µm). Store at 4 °C in glass containers.

Albumin barbital buffer solution. Dissolve 0.150 g of *bovine albumin R* in 20 ml of barbital buffer stock solution and dilute to 100 ml with *water R*.

Tannic acid solution. Dissolve 10 mg of *tannic acid R* in 100 ml of phosphate-buffered saline pH 7.2. Prepare immediately before use.

Guinea-pig complement. Prepare a pool of serum from the blood of not fewer than 10 guinea-pigs. Separate the serum from the clotted blood by centrifugation at about 4 °C. Store the serum in small amounts below – 70 °C. Immediately before starting complement-initiated haemolysis, dilute to 125-200 CH_{50} per millilitre with albumin barbital buffer solution and store in an ice-bath during the test.

Rubella antigen. Suitable rubella antigen for haemagglutination-inhibition titre (HIT). Titre > 256 HA units.

Preparation of tanned human red blood cells. Separate human red blood cells by centrifuging an appropriate volume of stabilised human blood and wash the cells at least 3 times with phosphate-buffered saline pH 7.2 and suspend at 2 per cent *V/V* in phosphate-buffered saline pH 7.2. Dilute 0.1 ml of tannic acid solution to 7.5 ml with phosphate-buffered saline pH 7.2 (final concentration 1.3 mg/l). Mix 1 volume of the freshly prepared dilution with 1 volume of human red blood cell suspension and incubate at 37 °C for 10 min. Collect the cells by centrifugation (400-800 *g* for 10 min),

discard the supernatant and wash the cells once with phosphate-buffered saline pH 7.2. Resuspend the tanned cells at 1 per cent *V/V* in phosphate-buffered saline pH 7.2.

Antigen coating of tanned human red blood cells. Take a suitable volume (V_s) of tanned cells, add 0.2 ml of rubella antigen per 1.0 ml of tanned cells and incubate at 37 °C for 30 min. Collect the cells by centrifugation (400-800 *g* for 10 min) and discard the supernatant, leaving a volume of 200 µl. Add a volume of albumin barbital buffer solution equivalent to the discarded supernatant, resuspend and collect the cells as described and repeat the washing procedure. Make up the remaining 200 µl to three-quarters of V_s, thereby obtaining the initial volume (V_i). Mix 900 µl of albumin barbital buffer solution with 100 µl of V_i, which is thereby reduced to the residual volume (V_r), and determine the initial absorbance at 541 nm (A). Dilute V_r by a factor equal to A using albumin barbital buffer solution, thereby obtaining the final adjusted volume $V_f = V_r \times A$ of sensitised human red blood cells and adjusting A to 1.0 ± 0.1 for a tenfold dilution.

Antibody binding of antigen-coated tanned human red blood cells. Prepare the following solutions in succession and in duplicate, using for each solution a separate half-micro cuvette (for example, disposable type) or test-tube:

(1) *Test solutions*. If necessary, adjust the immunoglobulin to be examined to pH 7, for example by addition of *1 M sodium hydroxide*. Dilute volumes of the preparation to be examined containing 30 mg and 40 mg of immunoglobulin with albumin barbital buffer solution and adjust the volume to 900 µl.

(2) *Reference solutions*. Prepare as for the test solutions using *human immunoglobulin BRP*.

(3) *Complement control*. 900 µl of albumin barbital buffer solution.

Add to each cuvette/test-tube 100 µl of sensitised human red blood cells and mix well.

Incubate at room temperature for 15 min, add 1000 µl of albumin barbital buffer solution, collect the cells by centrifugation (1000 *g* for 10 min) of the cuvette/test-tube and remove 1900 µl of the supernatant. Replace the 1900 µl with albumin barbital buffer solution and repeat the whole of the washing procedure, finally leaving a volume of 200 µl. Test samples may be stored in sealed cuvette/test-tubes at 4 °C for 24 h.

Complement-initiated haemolysis. To measure haemolysis, add 600 µl of albumin barbital buffer solution warmed to 37 °C to the test sample, resuspend the cells carefully by repeated pipetting (not fewer than 5 times) and place the cuvette in the thermostatted cuvette holder of a spectrophotometer. After 2 min, add 200 µl of diluted guinea-pig complement (125-200 CH_{50}/ml), mix thoroughly by pipetting twice and start immediately after the second pipetting the time-dependent recording of absorbance at 541 nm, using albumin barbital buffer solution as the compensation liquid. Stop the measurement if absorbance as a function of time has clearly passed the inflexion point.

Evaluation. Determine the slope (S) of the haemolysis curve at the approximate inflexion point by segmenting the steepest section in suitable time intervals Δt (for example, Δt = 1 min) and calculate S between adjacent intersection points, expressed as ΔA per minute. The largest value for S serves as (S_{exp}). In addition, determine the absorbance at the start of measurement (A_s) by extrapolating the curve, which is almost linear and parallel to the time axis within the first few minutes. Correct (S_{exp}) using the expression:

$$S' = \frac{S_{\exp}}{A_s}$$

Calculate the arithmetic mean of the values of S' for each preparation. Calculate the index of Fc function (I_{Fc}) from the expression:

$$I_{Fc} = \frac{100 \times \left(\overline{S'} - \overline{S'}_c\right)}{\overline{S'_s} - \overline{S'}_c}$$

$\overline{S'}$ = arithmetic mean of the corrected slope for the preparation to be examined,

$\overline{S'_s}$ = arithmetic mean of the corrected slope for the reference preparation,

$\overline{S'_c}$ = arithmetic mean of the corrected slope for the complement control.

Calculate the index of Fc function for the preparation to be examined: the value is not less than that stated in the leaflet accompanying the reference preparation.

01/2008:20710

2.7.10. ASSAY OF HUMAN COAGULATION FACTOR VII

Human coagulation factor VII is assayed by its biological activity as a factor VIIa-tissue factor complex in the activation of factor X in the presence of calcium ions and phospholipids. The potency of a factor VII preparation is estimated by comparing the quantity necessary to achieve a certain rate of factor Xa formation in a test mixture containing the substances that take part in the activation of factor X, and the quantity of the International Standard, or of a reference preparation calibrated in International Units, required to produce the same rate of factor Xa formation.

The International Unit is the factor VII activity of a stated amount of the International Standard, which consists of freeze-dried plasma. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Human coagulation factor VII concentrate BRP is calibrated in International Units by comparison with the International Standard.

The chromogenic assay method consists of 2 consecutive steps: the factor VII-dependent activation of factor X reagent mixture containing tissue factor, phospholipids and calcium ions, followed by enzymatic cleavage of a chromogenic factor Xa substrate into a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between the rate of factor Xa formation and the factor VII concentration. The assay is summarised in the following scheme.

Step 1

a) factor VII —(tissue factor, Ca^{2+})→ factor VIIa

b) factor X —(factor VIIa, Ca^{2+}; tissue factor/phospholipid)→ factor Xa

Step 2

chromogenic substrate —(factor Xa)→ peptide + chromophore

Both steps employ reagents that may be obtained commercially from a variety of sources. Although the composition of individual reagents may be subject to some variation, their essential features are described in the following specification.

REAGENTS

The coagulation factor reagent comprises purified proteins derived from human or bovine sources. These include factor X and thromboplastin tissue factor/phospholipid as factor VII activator. These proteins are partly purified and do not contain impurities that interfere with the activation of factor VII or factor X. Factor X is present in amounts giving a final concentration during the first step of the assay of 10-350 nmol/litre, preferably 14-70 nmol/litre. Thromboplastin from natural sources (bovine or rabbit brain) or synthetic preparations may be used as the tissue factor/phospholipid component. Thromboplastin suitable for use in prothrombin time determination is diluted 1:5 to 1:50 in buffer such that the final concentration of Ca^{2+} is 15-25 mmol/litre. The final factor Xa generation is performed in a solution containing human or bovine albumin at a concentration such that adsorption losses do not occur and which is appropriately buffered at pH 7.3-8.0. In the final incubation mixture, factor VII must be the only rate-limiting component and each reagent component must lack the ability to generate factor Xa on its own.

The second step comprises the quantification of the formed factor Xa employing a chromogenic substrate that is specific for factor Xa. Generally this consists of a short peptide of between three and five amino acids, bound to a chromophore group. On cleavage of this group from the peptide substrate, its absorption maximum shifts to a wavelength allowing its spectrophotometric quantification. The substrate is usually dissolved in *water R* and used at a final concentration of 0.2-2 mmol/litre. The substrate may also contain appropriate inhibitors to stop further factor Xa generation (addition of edetate).

ASSAY PROCEDURE

Reconstitute the entire contents of one ampoule of the reference preparation and the preparation to be examined by adding the appropriate quantity of *water R*; use within 1 h. Add sufficient prediluent to the reconstituted preparations to produce solutions containing between 0.5 IU and 2.0 IU of factor VII per millilitre.

Prepare further dilutions of reference and test preparations using an isotonic non-chelating buffer containing 1 per cent of bovine or human albumin, buffered preferably between pH 7.3 and 8.0. Prepare at least three separate, independent dilutions for each material, preferably in duplicate. Prepare the dilutions such that the final factor VII concentration is below 0.005 IU/ml.

Prepare a control solution that includes all components except factor VII.

Prepare all dilutions in plastic tubes and use within 1 h.

Step 1. Mix dilutions of the factor VII reference preparation and the preparation to be examined with an appropriate volume of the prewarmed coagulation factor reagent or a combination of its separate constituents, and incubate the mixture in plastic tubes or microplate wells at 37 °C. The concentrations of the various components during the factor Xa generation must be as specified above under the description of the reagents.

Allow the activation of factor X to proceed for a suitable time, usually terminating the reaction before the factor Xa concentration has reached its maximal level in order to obtain a satisfactory linear dose-response relationship. The activation time is also chosen to achieve linear production of factor Xa in time. Appropriate activation times are usually between 2 min and 5 min, but deviations are permissible if acceptable linearity of the dose-response relationship is thus obtained.

Step 2. Terminate the activation by the addition of a prewarmed reagent containing a chromogenic substrate. Quantify the rate of substrate cleavage, which must be linear with the concentration of factor Xa formed, by measuring the absorbance change at an appropriate wavelength using a spectrophotometer, either monitoring the absorbance continuously, thus allowing the initial rate of substrate cleavage to be calculated, or terminating the hydrolysis reaction after a suitable interval by lowering the pH by the addition of a suitable reagent, such as acetic acid (500 g/l $C_2H_4O_2$) or a citrate solution (1 mol/l) at pH 3. Adjust the hydrolysis time to achieve a linear development of chromophore with time. Appropriate hydrolysis times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (for example, *5.3*).

01/2008:20711

2.7.11. ASSAY OF HUMAN COAGULATION FACTOR IX

The principle of the assay is to measure the ability of a factor IX preparation to reduce the prolonged coagulation time of factor IX-deficient plasma. The reaction is accelerated by addition of a reagent containing phospholipid and a contact activator, e.g. kaolin, silica or ellagic acid. The potency is assessed by comparing the dose-response curve of the preparation to be examined to that of a reference preparation, calibrated in International Units.

The International Unit is the factor IX activity of a stated amount of the International Standard, which consists of a freeze-dried concentrate of human coagulation factor IX. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Human coagulation factor IX concentrate BRP is calibrated in International Units by comparison with the International Standard.

Reconstitute separately the preparation to be examined and the reference preparation as stated on the label and use immediately. Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulphate R* (10 µg of protamine sulphate neutralises 1 IU of heparin). Predilute the preparation to be examined and the reference preparation in factor IX-deficient plasma (for example *plasma substrate R2*) to produce solutions containing 0.5-2.0 IU/ml. Prepare at least 3 dilutions for each material, preferably in duplicate, using a suitable buffer solution (for example *imidazole buffer solution pH 7.3 R*) containing 10 g/l of bovine or human albumin. Use these dilutions immediately.

Use an apparatus suitable for measurement of coagulation times or carry out the assay with incubation tubes maintained in a water-bath at 37 °C. Place in each tube 0.1 ml of factor IX-deficient plasma (for example *plasma substrate R2*) and 0.1 ml of one of the dilutions of the reference preparation or of the preparation to be examined. Add to each tube 0.1 ml of a suitable Activated Partial Thromboplastin Time (APTT) reagent containing phospholipid and contact

activator and incubate the mixture for a recommended time at 37 °C. To each tube, add 0.1 ml of a 3.7 g/l solution of *calcium chloride R* previously heated to 37 °C. Using a timer, measure the coagulation time, i.e. the interval between the moment of the addition of the calcium chloride and the first indication of the formation of fibrin. The volumes given above may be adapted to the APTT reagent and apparatus used. Calculate the potency using the usual statistical methods (for example, *5.3*).

01/2008:20712

2.7.12. ASSAY OF HEPARIN IN COAGULATION FACTORS

Heparin is assayed as a complex with antithrombin III (AT) via its inhibition of coagulation factor Xa (anti-Xa activity). An excess of AT is maintained in the reaction mixture to ensure a constant concentration of the heparin-AT complex. Factor Xa is neutralised by the heparin-AT complex and the residual factor Xa hydrolyses a specific chromogenic peptide substrate to release a chromophore. The quantity of chromophore is inversely proportional to the activity of the heparin.

Factor Xa chromogenic substrate. Specific chromogenic substrate for factor Xa such as: *N*-benzoyl-L-isoleucyl-L-glutamyl-glycyl-L-arginine-4-nitroanilide hydrochloride. Reconstitute according to the manufacturer's instructions.

Dilution buffer. 6.05 g/l solution of *tris(hydroxymethyl)aminomethane R*. Adjust to pH 8.4 if necessary using *hydrochloric acid R*.

Test solution. Dilute the preparation to be examined with dilution buffer to obtain a solution expected to contain 0.1 IU of heparin per millilitre.

Reference solution. Dilute the heparin reference preparation with dilution buffer to obtain a solution containing 0.1 IU of heparin per millilitre.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Warm all solutions to 37 °C in a water-bath shortly before the test.

Distribute in a series of wells, 20 µl of normal human plasma and 20 µl of *antithrombin III solution R1*. Add to the wells a series of volumes (20 µl, 60 µl, 100 µl and 140 µl) of the test solution or the reference solution and make up the volume in each well to 200 µl using dilution buffer (0.02-0.08 IU of heparin per millilitre in the final reaction mixture).

End-point method. Transfer 40 µl from each well to a second series of wells, add 20 µl of *bovine factor Xa solution R* and incubate at 37 °C for 30 s. Add 40 µl of a 1 mmol/l solution of factor Xa chromogenic substrate and incubate at 37 °C for 3 min. Terminate the reaction by lowering the pH by the addition of a suitable reagent, such as a 20 per cent *V/V* solution of *glacial acetic acid R* and measure the absorbance at 405 nm (*2.2.25*). Appropriate reaction times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Kinetic method. Transfer 40 µl from each well to a second series of wells, add 20 µl of *bovine factor Xa solution R* and incubate at 37 °C for 30 s. Add 40 µl of a 2 mmol/l solution of factor Xa chromogenic substrate, incubate at 37 °C and measure the rate of substrate cleavage by continuous measurement of the absorbance change at 405 nm (*2.2.25*), thus allowing the initial rate of substrate cleavage to be calculated. This rate must be linear with the concentration of residual factor Xa.

Check the validity of the assay and calculate the heparin activity of the test preparation by the usual statistical methods for a slope-ratio assay (for example, *5.3*).

01/2008:20713

2.7.13. ASSAY OF HUMAN ANTI-D IMMUNOGLOBULIN

METHOD A

The potency of human anti-D immunoglobulin is determined by comparing the quantity necessary to produce agglutination of D-positive red blood cells with the quantity of a reference preparation, calibrated in International Units, required to produce the same effect.

The International Unit is the activity contained in a stated amount of the International Reference Preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organisation.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

Use pooled D-positive red blood cells, collected not more than 7 days earlier and suitably stored, obtained from not fewer than 4 group O R_1R_1 donors. To a suitable volume of the cells, previously washed 3 times with a 9 g/l solution of *sodium chloride R*, add an equal volume of *bromelains solution R*, allow to stand at 37 °C for 10 min, centrifuge, remove the supernatant liquid and wash 3 times with a 9 g/l solution of *sodium chloride R*. Suspend 20 volumes of the red blood cells in a mixture of 15 volumes of inert serum, 20 volumes of a 300 g/l solution of *bovine albumin R* and 45 volumes of a 9 g/l solution of *sodium chloride R*. Stand the resulting suspension in iced water, stirring continuously.

Using a calibrated automated dilutor, prepare suitable dilutions of the preparation to be examined and of the reference preparation using as diluent a solution containing 5 g/l of *bovine albumin R* and 9 g/l of *sodium chloride R*.

Use a suitable apparatus for automatic continuous analysis. The following protocol is usually suitable: maintain the temperature in the manifold, except for the incubation coils, at 15.0 °C. Pump into the manifold of the apparatus the red blood cell suspension at a rate of 0.1 ml/min and a 3 g/l solution of *methylcellulose 450 R* at a rate of 0.05 ml/min. Introduce the dilutions of the preparation to be examined and the reference preparation at a rate of 0.1 ml/min for 2 min, followed by the diluent solution at a rate of 0.1 ml/min for 4 min before the next dilution is introduced.

Introduce air at a rate of 0.6 ml/min. Incubate at 37 °C for 18 min and then disperse the rouleaux by introducing at a rate of 1.6 ml/min a 9 g/l solution of *sodium chloride R* containing a suitable wetting agent (for example, *polysorbate 20 R* at a final concentration of 0.2 g/l) to prevent disruption of the bubble pattern. Allow the agglutinates to settle and decant twice, first at 0.4 ml/min and then at 0.6 ml/min. Lyse the unagglutinated red blood cells with a solution containing 5 g/l of *octoxinol 10 R*, 0.2 g/l of *potassium ferricyanide R*, 1 g/l of *sodium hydrogen carbonate R* and 0.05 g/l of *potassium cyanide R* at a rate of 2.5 ml/min. A ten-minute delay coil is introduced to allow for conversion of the haemoglobin. Continuously record the absorbance (*2.2.25*) of the haemolysate at a

wavelength between 540 nm and 550 nm. Determine the range of antibody concentrations over which there is a linear relationship between concentration and the resultant change in absorbance (ΔA). From the results, prepare a standard curve and use the linear portion of the curve to determine the activity of the preparation to be examined.

Calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

METHOD B

The potency of human anti-D immunoglobulin is determined by competitive enzyme-linked immunoassay on erythrocyte-coated microtitre plates. The method is based on the competitive binding between a polyclonal anti-D immunoglobulin preparation and a biotinylated monoclonal anti-D antibody directed against a D-antigen specific epitope. The activity of the preparation to be examined is compared with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of International Reference Preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organisation.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

MATERIALS

Reagents not specified are of analytical grade.

PBS (Phosphate-buffered saline). Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R*, 0.2 g of *potassium dihydrogen phosphate R* and 0.2 g of *sodium azide R* in *water R* and dilute to 1000 ml with the same solvent.

TBS (Tris-buffered saline). Dissolve 8.0 g of *sodium chloride R* and 0.6 g of *tris(hydroxymethyl) aminomethane R* in *water R*. Adjust to pH 7.2 (*2.2.3*) with *1 M hydrochloric acid* and dilute to 1000 ml with the same solvent.

Papain solution. Prepare a solution by stirring 1 g of *papain R* at 37 °C for 30 min in 10 ml of *0.067 M phosphate buffer solution pH 5.4 R*, centrifuge at 10 000 *g* for 5 min and filter through a membrane with a pore size of 0.22 µm. To activate, combine 1 ml of the filtrate with 1 ml of a 48.44 g/l solution of *L-cysteine R* and 1 ml of a 3.72 g/l solution of *sodium edetate R* and dilute to 10 ml with *0.067 M phosphate buffer solution pH 5.4 R*. Freeze in aliquots at – 20 °C or below.

Red blood cells. Use pooled D-positive red blood cells obtained from not fewer than 3 group O R_2R_2 donors. Wash the cells 4 times with PBS. Centrifuge the cells at 1800 *g* for 5 min, mix a suitable volume of prewarmed packed cells with a suitable volume of prewarmed papain solution (2 volumes to 1 volume has been found suitable) and incubate at 37 °C for 10 min. Wash the cells 4 times with PBS. Store at 4 °C in an appropriate stabiliser for up to 1 week.

Biotinylated Brad-5. Use according to instructions.

Alkaline phosphatase-conjugated avidin/streptavidin reagent. Preferably modified to combine high specific activity with low non-specific binding. Use according to instructions.

Substrate solution. Use *para*-nitrophenyl phosphate according to instructions.

Cell fixation buffer. Dissolve 18.02 g of *glucose R*, 4.09 g of *sodium chloride R*, 1.24 g of *boric acid R*, 10.29 g of *sodium citrate R* and 0.74 g of *sodium edetate R* in *water R*. Adjust to pH 7.2-7.3 (*2.2.3*) using *1 M sodium hydroxide* or *1 M hydrochloric acid*, and dilute to 1000 ml with *water R*. Use directly from storage at 4 °C.

Glutaraldehyde solution. Immediately before use, add 90 µl of a 250 g/l solution of *glutaraldehyde R* to 24 ml of cold PBS.

Microtitre plates. Plates to be coated with red blood cells are flat-bottomed polystyrene plates with surface properties optimised for enzyme immunoassay and high protein-binding capacity. Plates used to prepare immunoglobulin dilutions are U or V-bottomed polystyrene or poly(vinyl chloride) plates.

METHOD

Prepare a 0.1 per cent (*V/V*) suspension of papain-treated red blood cells in cold cell fixation buffer. Pipette 50 µl into each well of the flat-bottomed microtitre plate.

Centrifuge the plate at 350 *g* for 3 min, preferably at 4 °C. Without removing the supernatant, gently add 100 µl of glutaraldehyde solution to each well and leave for 10 min.

Drain the wells by quickly inverting the plate and wash 3 times with 250-300 µl of PBS. This may be done manually or using a suitable automated plate washer. Either carry out the assay as described below, or store the plate at 4 °C after draining off the PBS and adding 100 µl of cell fixation buffer per well and sealing with plastic film. Plates can be stored at 4 °C for up to 1 month.

Test solutions. For freeze-dried preparations, reconstitute as stated on the label. Prepare 4 independent replicates of 5 serial two-fold dilutions starting with 30 IU/ml in PBS containing 10 g/l of *bovine albumin R*. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Reference solutions. Reconstitute the reference preparation according to instructions. Prepare 4 independent replicates of 5 serial two-fold dilutions starting with 30 IU/ml in PBS containing 10 g/l of *bovine albumin R*.

Using U or V-bottomed microtitre plates, add 35 µl of each of the dilutions of the test solution or reference solution to each of a series of wells. To each well add 35 µl of biotinylated Brad-5 at 250 ng/ml.

Empty the wells of the red cell-coated plate by inverting and draining on a paper towel. Add 250 µl of PBS containing 20 g/l of *bovine albumin R* and leave at room temperature for 30 min.

Empty the wells of the red cell-coated plate by inverting and draining on a paper towel and transfer 50 µl from each of the dilutions of the test solution or reference solution containing biotinylated Brad-5 into the wells. Use 50 µl of PBS containing 10 g/l of *bovine albumin R* as negative control. Seal the plate with plastic film and incubate at room temperature for 1 h.

Remove liquid from the wells of the red cell-coated plate and wash 3 times with 250-300 µl of TBS.

Dilute the alkaline phosphatase-conjugated avidin/streptavidin reagent in TBS containing 10 g/l of *bovine albumin R* and add 50 µl to each well. Incubate for 30 min at room temperature.

Remove liquid from the wells of the red cell-coated plate and wash 3 times with 250-300 µl of TBS.

Add 100 µl of substrate solution to each of the wells and incubate at room temperature for 10 min in the dark. To stop the reaction, add 50 µl of *3 M sodium hydroxide* to each of the wells.

Measure the absorbances at 405 nm. and substract the negative control reading. Use the absorbance values in the linear range of the titration curve to estimate the potency of the preparation to be examined by the usual statistical methods (*5.3*).

METHOD C

The potency of human anti-D immunoglobulin is determined by flow cytometry in a microtitre plate format. The method is based on the specific binding between anti-D immunoglobulin and D-positive red blood cells. The activity of the preparation to be examined is compared with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of International Reference Preparation. The equivalence in International Units of the International Reference preparation is stated by the World Health Organisation.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

MATERIALS

Reagents not specified are of analytical grade.

PBS. Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R* and 0.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000 ml with the same solvent.

PBS-BSA solution. PBS containing 10.0 g/l of *bovine albumin R*.

Red blood cells. Use D-positive red blood cells obtained from a group O R_1R_1 donor within 2 weeks of collection. Store if necessary in an appropriate stabiliser at 4 °C. Wash the cells at least twice with PBS-BSA solution and prepare a suspension containing 1×10^4 cells per microlitre but not more than 5×10^4 cells per microlitre in PBS-BSA solution.

Use D-negative red blood cells obtained from a group O rr donor and prepared similarly.

Secondary antibody. Use a suitable fluorescent dye conjugated anti-IgG antibody-fragment specific for human IgG or parts of it. Store and use according to the manufacturer's instructions.

Microtitres plates. Use flat-bottomed plates without surface treatment for enzyme immunoassays.

METHOD

Test solutions. For freeze-dried preparations, reconstitute as stated on the label. Prepare at least 3 independent replicates of at least 3 serial 1.5 or two-fold dilutions starting with a concentration in the range of 1.2-0.15 IU/ml using PBS/BSA solution as diluent. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Reference solutions. Reconstitute the reference preparation according to instructions. Prepare at least 3 independent replicates of at least 3 serial 1.5 or two-fold dilutions starting with a concentration in the range of 1.2-0.15 IU/ml using PBS-BSA solution as diluent. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Distribute 50 µl of the D-positive red blood cells into each well of a microtitre plate. Add 50 µl of each of the dilutions of the test solution or reference solution to each of a series of wells. Use 50 µl of PBS-BSA solution as negative control. Distribute 50 µl of the D-negative red blood cells into 4 wells of the same microtitre plate and add 50 µl of the lowest dilution of the test preparation. To monitor spurious reactions distribute 50 µl of the D-positive red blood cells into 4 wells of the same microtitre plate and add 50 µl of PBS-BSA solution. Seal with plastic film and incubate at 37 °C for 40 min.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and wash the cells with 200-250 µl of PBS-BSA solution. Repeat this at least once.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and add 50 µl of the secondary antibody diluted with PBS-BSA solution to a suitable protein concentration. Seal with plastic film and incubate, protected from light, at room temperature for 20 min.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and wash the cells with 200-250 µl of PBS-BSA solution. Repeat this at least once.

Centrifuge the plates at 50 *g* for 3 min, resuspend the cells into 200-250 µl of PBS. Transfer the cell suspension into a tube suitable for the flow cytometry equipment available and further dilute by adding PBS to allow a suitable flow rate.

Proceed immediately with measurement of the median fluorescence intensity in a flow cytometer. Record at least 10 000 events without gating but excluding debris.

Use the median fluorescence intensity in the linear range of the dose response curve to estimate the potency of the preparation to be examined by the usual statistical methods (*5.3*).

01/2008:20714

2.7.14. ASSAY OF HEPATITIS A VACCINE

The assay of hepatitis A vaccine is carried out either *in vivo*, by comparing in given conditions its capacity to induce specific antibodies in mice with the same capacity of a reference preparation, or *in vitro*, by an immunochemical determination of antigen content.

IN VIVO ASSAY

The test in mice shown below is given as an example of a method that has been found suitable for a given vaccine; other validated methods may also be used.

Selection and distribution of the test animals. Use in the test healthy mice from the same stock, about 5 weeks old and from a strain shown to be suitable. Use animals of the same sex. Distribute the animals in at least 7 equal groups of a number suitable for the requirements of the assay.

Determination of potency of the vaccine to be examined. Using a 9 g/l solution of *sodium chloride R* containing the aluminium adjuvant used for the vaccine, prepare at least 3 dilutions of the vaccine to be examined and matching dilutions of the reference preparation. Allocate the dilutions one to each of the groups of animals and inject subcutaneously not more than 1.0 ml of each dilution into each animal in the group to which that dilution is allocated. Maintain a group of unvaccinated controls, injected subcutaneously with the same volume of diluent. After 28 to 32 days, anaesthetise and bleed all animals, keeping the individual sera separate. Assay the individual sera for specific antibodies against hepatitis A virus by a suitable immunochemical method (*2.7.1*).

Calculations. Carry out the calculations by the usual statistical methods for an assay with a quantal response (*5.3*).

From the distribution of reaction levels measured on all the sera in the unvaccinated group, determine the maximum reaction level that can be expected to occur in an unvaccinated animal for that particular assay. Any response

in vaccinated animals that exceeds this level is by definition a seroconversion.

Make a suitable transformation of the percentage of animals showing seroconversion in each group (for example, a probit transformation) and analyse the data according to a parallel-line log dose-response model. Determine the potency of the test preparation relative to the reference preparation.

Validity conditions. The test is not valid unless:

- for both the test and the reference vaccine, the ED_{50} lies between the smallest and the largest doses given to the animals,
- the statistical analysis shows no significant deviation from linearity or parallelism,
- the confidence limits (P = 0.95) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

Potency requirement. The upper confidence limit (P = 0.95) of the estimated relative potency is not less than 1.0.

IN VITRO ASSAY

Carry out an immunochemical determination (*2.7.1*) of antigen content with acceptance criteria validated against the *in vivo* test. The acceptance criteria are approved for a given reference preparation by the competent authority in the light of the validation data.

01/2008:20715

2.7.15. ASSAY OF HEPATITIS B VACCINE (rDNA)

The assay of hepatitis B vaccine (rDNA) is carried out either *in vivo*, by comparing in given conditions its capacity to induce specific antibodies against hepatitis B surface antigen (HBsAg) in mice or guinea-pigs with the same capacity of a reference preparation, or *in vitro*, by an immunochemical determination of the antigen content.

IN VIVO ASSAY

Selection and distribution of the test animals. Use in the test healthy mice from the same stock, about 5 weeks old. The strain of mice used for this test must give a significant slope for the dose-response curve to the antigen; mice with haplotype H-2^q or H-2^d are suitable. Healthy guinea-pigs weighing 300 g to 350 g (about 7 weeks old) from the same stock are also suitable. Use animals of the same sex. Distribute the animals in at least 7 equal groups of a number appropriate to the requirements of the assay.

Determination of potency of the vaccine to be examined. Using a 9 g/l solution of *sodium chloride R* containing the aluminium adjuvant used for the vaccine or another appropriate diluent, prepare at least three dilutions of the vaccine to be examined and matching dilutions of the reference preparation. Allocate the dilutions one to each of the groups of animals and inject intraperitoneally not more than 1.0 ml of each dilution into each animal in the group to which that dilution is allocated. One group of animals remains unvaccinated and is injected intraperitoneally with the same volume of diluent. After an appropriate time interval (for example, 4 to 6 weeks), anaesthetise and bleed the animals, keeping the individual sera separate. Assay the individual sera for specific antibodies against HBsAg by a suitable immunochemical method (*2.7.1*).

Calculations. Calculations are carried out by the usual statistical methods for an assay with a quantal response (*5.3*).

From the distribution of reaction levels measured on all the sera in the unvaccinated group, the maximum reaction level that can be expected to occur in an unvaccinated animal for that particular assay is determined. Any response in vaccinated animals that exceeds this level is by definition a seroconversion.

Make a suitable transformation of the percentage of animals showing seroconversion in each group (for example, a probit transformation) and analyse the data according to a parallel-line log dose-response model. Determine the potency of the test preparation relative to the reference preparation.

Validity conditions. The test is not valid unless:

- for both the test and the reference vaccine, the ED_{50} lies between the smallest and the largest doses given to the animals,
- the statistical analysis shows no significant deviation from linearity or parallelism,
- the confidence limits (P = 0.95) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

Potency requirement. The upper confidence limit (P = 0.95) of the estimated relative potency is not less than 1.0.

IN VITRO ASSAY

Carry out an immunochemical determination (*2.7.1*) of antigen content with acceptance criteria validated against the *in vivo* test.

Enzyme-linked immunosorbent assay (ELISA) and radio-immunoassay (RIA) using monoclonal antibodies specific for protection-inducing epitopes of HBsAg have been shown to be suitable. Suitable numbers of dilutions of the vaccine to be examined and the reference preparation are used and a parallel-line model is used to analyse the data which may be suitably transformed. Kits for measuring HBsAg *in vitro* are commercially available and it is possible to adapt their test procedures for use as an *in vitro* potency assay.

The acceptance criteria are approved for a given reference preparation by the competent authority in the light of the validation data.

Hepatitis B vaccine (rDNA) method A BRP and *hepatitis B vaccine (rDNA) method B BRP* are suitable for the *in vitro* assay of certain vaccines as described in the accompanying leaflet.

01/2008:20716

2.7.16. ASSAY OF PERTUSSIS VACCINE (ACELLULAR)

The capacity of the vaccine to induce the formation of specific antibodies is compared with the same capacity of a reference preparation examined in parallel; antibodies are determined using suitable immunochemical methods (*2.7.1*) such as enzyme-linked immunosorbent assay (ELISA). The test in mice shown below uses a three-point model but, after validation, for routine testing a single-dilution method may be used.

Reference vaccine. A batch of vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative

batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The stability of the reference vaccine shall be documented.

Reference antiserum. Bordetella pertussis mouse antiserum BRP is suitable for use as a reference antiserum.

Requirement. The capacity of the vaccine to induce antibodies is not significantly (P = 0.95) less than that of the reference vaccine.

The following test model is given as an example of a method that has been found to be satisfactory.

Selection and distribution of test animals. Use in the test healthy mice (for example, CD1 strain) of the same stock, about 5 weeks old. Distribute the animals in 6 groups of a number appropriate to the requirements of the assay. Use 3 dilutions of the vaccine to be examined and 3 dilutions of a reference preparation and attribute each dilution to a group of mice. Inject intraperitoneally or subcutaneously into each mouse 0.5 ml of the dilution attributed to its group.

Collection of serum samples. 4 to 5 weeks after vaccination, bleed the mice individually under anaesthesia. Store the sera at – 20 °C until tested for antibody content.

Antibody determination. Assay the individual sera for content of specific antibodies to each component using a validated method such as the ELISA test shown below.

ELISA test. Microtitre plates (poly(vinyl chloride) or polystyrene as appropriate for the specific antigen) are coated with the purified antigen at a concentration of 100 ng per well. After washing, unreacted sites are blocked by incubating with a solution of bovine serum albumin and then washed. Two-fold dilutions of sera from mice immunised with test or reference vaccines are made on the plates. After incubation at 22-25 °C for 1 h, the plates are washed. A suitable solution of anti-mouse IgG enzyme conjugate is added to each well and incubated at 22-25 °C for 1 h. After washing, a chromogenic substrate is added from which the bound enzyme conjugate liberates a chromophore which can be quantified by measurement of absorbance (*2.2.25*). The test conditions are designed to obtain a linear response for absorbance with respect to antibody content over the range of measurement used and absorbance values within the range 0.1 to 2.0.

A reference antiserum of assigned potency is used in the test and serves as the basis for calculation of the antibody levels in test sera. A standardised control serum is also included in the test.

The test is not valid if:

- the value found for the control serum differs by more than 2 standard deviations from the assigned value,
- the confidence limits (P = 0.95) are less than 50 per cent or more than 200 per cent of the estimated potency.

Calculations. The antibody titres in the sera of mice immunised with reference and test vaccines are calculated and from the values obtained the potency of the test vaccine in relation to the reference vaccine is calculated by the usual statistical methods (*5.3*).

01/2008:20717

2.7.17. ASSAY OF HUMAN ANTITHROMBIN III

The antithrombin III content of the preparation to be examined is determined by comparing its ability to inactivate thrombin in the presence of an excess of heparin with the same ability of a reference preparation of human antithrombin III concentrate calibrated in International Units. Varying quantities of the preparation to be examined are mixed with a given quantity of thrombin and the remaining thrombin activity is determined using a suitable chromogenic substrate.

The International Unit is the activity of a stated amount of the International Standard for human antithrombin III concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Method. Prepare 2 independent series of 3 or 4 dilutions in the range 1/75 to 1/200 from 1 IU/ml, for both the preparation to be examined and the reference preparation, using *tris-EDTA BSA buffer solution pH 8.4 R* containing 15 IU of heparin per millilitre.

Warm 200 µl of each dilution at 37 °C for 1-2 min. Add to each dilution 200 µl of a solution of *bovine thrombin R* containing 2 IU/ml in *tris-EDTA BSA buffer solution pH 8.4 R*. Mix and maintain at 37 °C for exactly 1 min. Add 500 µl of a suitable chromogenic substrate (for example, D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide, reconstituted in *water R* to give a solution containing 4 mmol/l and further diluted to a concentration suitable for the assay using *tris-EDTA BSA buffer solution pH 8.4 R* without albumin). Immediately start measurement of the change in absorbance at 405 nm (*2.2.25*), continuing the measurement for at least 30 s. Calculate the rate of change of absorbance (ΔA/min). (Alternatively, an end-point assay may be used by stopping the reaction with acetic acid and measuring the absorbance at 405 nm.)

The rate of change of absorbance (ΔA/min) is inversely proportional to antithrombin III activity.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (*5.3*).

01/2008:20718

2.7.18. ASSAY OF HUMAN COAGULATION FACTOR II

Human coagulation factor II is assayed following specific activation to form factor IIa. Factor IIa is estimated by comparing its activity in cleaving a specific chromogenic peptide substrate with the same activity of the International Standard or of a reference preparation calibrated in International Units.

The International Unit is the factor II activity of a stated amount of the International Standard which consists of a freeze-dried concentrate of human blood coagulation factor II. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The chromogenic assay method consists of 2 steps: snake venom-dependent activation of factor II, followed by enzymatic cleavage of a chromogenic factor IIa substrate to form a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between factor IIa activity and the cleavage of the chromogenic substrate.

REAGENTS

Viper venom specific factor II activator (Ecarin). A protein derived from the venom of the saw-scaled viper (*Echis carinatus*) which specifically activates factor II. Reconstitute according to the manufacturer's instructions. Store the reconstituted preparation at 4 °C and use within 1 month.

Factor IIa chromogenic substrate. Specific chromogenic substrate for factor IIa such as: *H*-D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide dihydrochloride, 4-toluenesulphonyl-glycyl-prolyl-L-arginine-4-nitroanilide, *H*-

D-cyclohexylglycyl-α-aminobutyryl-L-arginine-4-nitroanilide, D-cyclohexylglycyl-L-alanyl-L-arginine-4-nitroanilide diacetate. Reconstitute according to the manufacturer's instructions.

Dilution buffer. Solution containing 6.06 g/l of *tris(hydroxymethyl)aminomethane R*, 17.53 g/l of *sodium chloride R*, 2.79 g/l of *(ethylenedinitrilo)tetra-acetic acid R* and 1 g/l of *bovine albumin R* or *human albumin R*. Adjust to pH 8.4 if necessary, using *hydrochloric acid R*.

METHOD

Test solution. Dilute the preparation to be examined with dilution buffer to obtain a solution containing 0.015 IU of factor II per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Reference solution. Dilute the reference preparation to be examined with dilution buffer to obtain a solution containing 0.015 IU of factor II per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Warm all solutions to 37 °C in a water-bath shortly before the test.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Using a microtitre plate maintained at 37 °C, add 25 µl of each dilution of the test solution or the reference solution to each of a series of wells. To each well add 125 µl of dilution buffer, then 25 µl of ecarin and incubate for exactly 2 min. To each well add 25 µl of factor IIa chromogenic substrate.

Read the rate of change of absorbance (*2.2.25*) at 405 nm continuously over a period of 3 min and obtain the mean rate of change of absorbance (ΔA/min). If continuous monitoring is not possible, read the absorbance at 405 nm at suitable consecutive intervals, for instance 40 s, plot the absorbances against time on a linear graph and calculate ΔA/min as the slope of the line. From the ΔA/min values of each individual dilution of standard and test preparations, calculate the potency of the preparation to be examined and check the validity of the assay by the usual statistical methods (*5.3*).

01/2008:20719

2.7.19. ASSAY OF HUMAN COAGULATION FACTOR X

Human coagulation factor X is assayed following specific activation to form factor Xa. Factor Xa is estimated by comparing its activity in cleaving a specific chromogenic peptide substrate with the same activity of the International Standard or of a reference preparation calibrated in International Units.

The International Unit is the factor X activity of a stated amount of the International Standard which consists of a freeze-dried concentrate of human coagulation factor X. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The chromogenic assay method consists of 2 steps: snake venom-dependent activation of factor X, followed by enzymatic cleavage of a chromogenic factor Xa substrate to form a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between factor Xa activity and the cleavage of the chromogenic substrate.

REAGENTS

Russell's viper venom specific factor X activator (RVV). A protein derived from the venom of Russell's viper (*Vipera russelli*) which specifically activates factor X. Reconstitute according to the manufacturer's instructions. Store the reconstituted preparation at 4 °C and use within 1 month.

Factor Xa chromogenic substrate. Specific chromogenic substrate for factor Xa such as: *N*-α-benzyloxycarbonyl-D-arginyl-L-glycyl-L-arginine-4-nitroanilide dihydrochloride, *N*-benzoyl-L-isoleucyl-L-glutamyl-glycyl-L-arginine-4-nitroanilide hydrochloride, methanesulphonyl-D-leucyl-glycyl-L-arginine-4-nitroanilide, methoxycarbonyl-D-cyclohexylalanyl-glycyl-L-arginine-4-nitroanilide acetate. Reconstitute according to the manufacturer's instructions.

Dilution buffer. Solution containing 3.7 g/l of *tris(hydroxymethyl)aminomethane R*, 18.0 g/l of *sodium chloride R*, 2.1 g/l of *imidazole R*, 0.02 g/l of *hexadimethrine bromide R* and 1 g/l of *bovine albumin R* or *human albumin R*. Adjust to pH 8.4 if necessary using *hydrochloric acid R*.

METHOD

Test solution. Dilute the preparation to be examined with dilution buffer to obtain a solution containing 0.18 IU of factor X per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Reference solution. Dilute the reference preparation to be examined with dilution buffer to obtain a solution containing 0.18 IU of factor X per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Warm all solutions to 37 °C in a water-bath shortly before the test.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Using a microtitre plate maintained at 37 °C, add 12.5 µl of each dilution of the test solution or the reference solution to each of a series of wells. To each well add 25 µl of RVV and incubate for exactly 90 s. To each well add 150 µl of factor Xa chromogenic substrate, diluted 1 in 6 in dilution buffer.

Read the rate of change of absorbance (*2.2.25*) (at 405 nm continuously over a period of 3 min and obtain the mean rate of change of absorbance (ΔA/min). If continuous monitoring is not possible, read the absorbance at 405 nm at suitable consecutive intervals, for instance 40 s, plot the absorbances against time on a linear graph and calculate ΔA/min as the slope of the line. From the ΔA/min values of each individual dilution of standard and test preparations, calculate the potency of the preparation to be examined and check the validity of the assay by the usual statistical methods (*5.3*).

01/2008:20720

2.7.20. *IN VIVO* ASSAY OF POLIOMYELITIS VACCINE (INACTIVATED)

The capacity of the vaccine to induce the formation of neutralising antibodies is determined *in vivo* by one of the following methods.

TEST IN CHICKS OR GUINEA-PIGS

Prepare a suitable series of not fewer than 3 dilutions of the vaccine to be examined using a suitable buffered saline solution. Distribute either guinea-pigs weighing 250-350 g or 3-week-old chicks into groups of 10, and allocate a group to each dilution of the vaccine. Inject intramuscularly into each animal 0.5 ml of the dilution intended for its group. Bleed the animals after 5-6 days and separate the sera. Examine the sera for the presence of neutralising antibodies, at a dilution of 1 in 4, to each of the human poliovirus types 1, 2 and 3. Mix 100 $CCID_{50}$ of virus with the dilution of serum and incubate at 37 °C for 4.5-6 h. Keep at 5 ± 3 °C for 12-18 h where necessary for consistency of results. Inoculate the mixtures into cell cultures for the detection of unneutralised virus and read the results up to 7 days after inoculation. For each group of animals, note the number of sera that have neutralising antibodies and calculate the dilution of the vaccine that gives an antibody response in 50 per cent of the animals. Carry out in parallel a control test using a suitable reference preparation. The vaccine complies with the test if a dilution of 1 to 100 or more produces an antibody response for each of the 3 types of virus in 50 per cent of the animals.

TEST IN RATS

A suitable *in vivo* assay method consists of intramuscular injection into the hind limb(s) of not fewer than 3 dilutions of the vaccine to be examined and a reference vaccine, using for each dilution a group of 10 specific pathogen-free rats of a suitable strain. Use of 4 dilutions is often necessary to obtain valid results for all 3 serotypes. The number of animals per group must be sufficient to obtain results that meet the validity criteria; groups of 10 rats are usually sufficient, although valid results may be obtained with fewer animals per group. If animals of different sex are used, males and females are evenly distributed between all groups. A weight range of 175-250 g has been found to be suitable. An inoculum of 0.5 ml per rat is used. The dose range is chosen such that a dose response to all 3 poliovirus types is obtained. Bleed the animals after 20-22 days. Neutralising titres against all 3 poliovirus types are measured separately using 100 $CCID_{50}$ of the Sabin strains as challenge viruses, Vero or Hep2 as indicator cells, and neutralisation conditions of 3 h at 35-37 °C followed by 18 h at 2-8 °C where necessary for consistency of results. Results are read following fixation and staining after 7 days of incubation at 35 °C. For a valid antibody assay, the titre of each challenge virus must be shown to be within the range 10 $CCID_{50}$ to 1000 $CCID_{50}$ and the neutralising antibody titre of a control serum must be within 2 twofold dilutions of the geometric mean titre of the serum. The potency is calculated by comparison of the proportion of responders for the vaccine to be examined and the reference vaccine by the probit method or, after validation, using a parallel-line model. For the probit method it is necessary to establish a cut-off neutralising antibody titre for each poliovirus type to define a responder. Due to interlaboratory variation, it is not possible to define cut-off values that could be applied by all laboratories. Rather, the cut-off values are determined for each laboratory based on a minimum series of 3 tests with the reference vaccine. The mid-point on a $\log_2$ scale of the minimum and maximum geometric mean titres of the series of 3 or more tests is used as the cut-off value. For each of the 3 poliovirus types, the potency of the vaccine is not significantly less than that of the reference preparation. The test is not valid unless:

- for both the vaccine to be examined and the reference vaccine, the ED_{50} lies between the smallest and the largest doses given to the animals;
- the statistical analysis shows no significant deviation from linearity or parallelism;
- the confidence limits (P = 0.95) are not less than 25 per cent and not more than 400 per cent of the estimated potency.

The following section is published for information.

Guideline on waiving of the *in vivo* assay of poliomyelitis vaccine (inactivated) and its combinations

This guideline applies to vaccines derived from wild strains of poliovirus. The validation described should be carried out for each product before waiving of the in vivo assay, and should be repeated wherever there is a substantial change to the manufacturing process that may affect the in vitro or in vivo assays.

The European convention on the protection of vertebrate animals used for experimental and other scientific purposes requires that tests in animals shall not be carried out if a scientifically satisfactory alternative is reasonably and practically available. The aim of this guideline is therefore to promote waiving of the *in vivo* assay wherever it can be shown for a given product that the *in vitro* assay (D-antigen determination) gives sufficient assurance of satisfactory potency for routine batch control.

For the *in vivo* assay, the test in rats is considered to be the method of choice. For vaccines that are assayed using chicks or guinea-pigs and that have an established record of production history, the *in vivo* assay may be waived if the rat assay is also applied to the batches included in the validation study described below. For vaccines not yet approved, the results of the rat assay on all final bulks should be included in all data generated for demonstration of consistency of production before waiving of the *in vivo* assay.

Once the *in vivo* assay has been waived, batches of vaccine will be released on the basis of the *in vitro* assay, and the *in vivo* assay should not be used as an alternative for the release of a batch that fails the *in vitro* assay. Repetition of the *in vitro* assay may be performed according to an authorised procedure.

PROCEDURE

The following conditions should be met before performance of the validation study:

- appropriate experience of the rat assay;
- full validation of the D-antigen assay (linearity, repeatability, intermediate precision, accuracy and limits of quantification);
- establishment of acceptance criteria for the D-antigen assay based on a suitable number of consecutive final lots;
- establishment of production consistency on recent final bulks using the currently approved *in vivo* assay; the final bulks should correspond to the final lots used to establish the acceptance criteria for the D-antigen assay and should represent different inactivated harvests of each of the 3 types of poliovirus.

The validation study should be performed on:

- a final bulk/lot that is representative of the current production method;
- 2 sub-potent batches prepared, for example, by heating normal vaccine or mixing it with heat-treated vaccine; the sub-potent batches should have expected titres of about half that of the representative final bulk/lot.

These batches are assayed using as reference standard a homologous production batch:

– by the currently approved *in vivo* assay for the vaccine;
– by the rat assay where this is not the currently approved *in vivo* assay;
– by the D-antigen assay.

Waiving of the *in vivo* assay is acceptable if the representative final bulk/lot complies with the *in vivo* and *in vitro* assays and the sub-potent batches fail to comply. If a sub-potent batch fails to comply with the D-antigen assay but complies with the *in vivo* assay, the latter may be repeated.

01/2008:20721

2.7.21. ASSAY OF HUMAN VON WILLEBRAND FACTOR

The biological functions of human von Willebrand factor are numerous. At present, its ristocetin cofactor activity and its collagen binding activity can be utilised for assays. The potency of human von Willebrand factor is determined by comparing, in given conditions, its activity with the same activity of a reference preparation calibrated against the International Standard, in International Units where applicable.

The International Unit is the activity of a stated amount of the International Standard, which consists of a freeze-dried human von Willebrand factor concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organisation (WHO).

RISTOCETIN COFACTOR ASSAY

The ristocetin cofactor activity of von Willebrand factor is determined by measuring agglutination of a suspension of platelets in the presence of ristocetin A. The assay can be carried out for quantitative determinations by using automated instruments, or for semi-quantitative determinations by visually assessing the endpoint of agglutination in a dilution series. Quantitative assays are preferred.

REAGENTS

Suspension of platelets. Use standardised and, for example, formaldehyde- or paraformaldehyde-fixed preparations of freshly isolated and washed human platelets. The suspension may also be freeze-dried. An appropriate amount of ristocetin A is added if necessary. Some platelet reagents may already contain ristocetin A.

Reference preparation. The reference preparation for von Willebrand factor is the WHO International Standard for von Willebrand factor concentrate.

METHOD

Semi-quantitative assay. Prepare suitable dilutions of the preparation to be examined and of the reference preparation, using as diluent a solution containing 9 g/l of *sodium chloride R* and 10-50 g/l of *human albumin R*. Add to each dilution an appropriate amount of the suspension of platelets and, if necessary, of ristocetin A. Mix on a glass slide by moving it gently in circles for 1 min. Allow to stand for a further 1 min and read the result against a dark background with side lighting. The last dilution which clearly shows visible agglutination indicates the ristocetin cofactor titre of the sample. Use diluent as a negative control.

Quantitative Assay. Reconstitute the entire contents of 1 ampoule of the reference preparation and the preparation to be examined by adding the appropriate quantity of the recommended diluent (for example *water R*); use immediately. Add sufficient prediluent to the reconstituted preparations to produce solutions containing 0.5-2.0 IU/ml. The prediluent consists of an isotonic non-chelating buffer containing, for example, 1-5 per cent of human or bovine albumin, and tris(hydroxymethyl)aminomethane or imidazole, appropriately buffered.

The test is performed in accordance with the manufacturer's instructions with at least 2 dilution series with as many dilutions as are needed to obtain a total of at least 3 different concentrations in the linear range of the assay.

Check the validity of the assay and calculate the potency of the test preparation using the usual statistical methods (for example, *5.3*).

COLLAGEN-BINDING ASSAY

Collagen-binding is determined by an enzyme-linked immunosorbent assay on collagen-coated microtitre plates. The method is based on the specific binding of von Willebrand factor to collagen fibrils and the subsequent binding of polyclonal anti-von Willebrand factor antibody conjugated to an enzyme, which on addition of a chromogenic substrate yields a product that can be quantitated spectrophotometrically. Under appropriate conditions, there is a linear relationship between von Willebrand factor collagen-binding and absorbance.

REAGENTS

Collagen. Use native equine or human fibrils of collagen type I or III. For ease of handling, collagen solutions may be used.

Collagen diluent. Dissolve 50 g of *glucose R* in *water R*, adjust to pH 2.7-2.9 with *1 M hydrochloric acid* and dilute to 1000 ml with *water R*.

Phosphate-buffered saline (PBS). Dissolve 8.0 g of *sodium chloride R*, 1.05 g of *disodium hydrogen phosphate dihydrate R*, 0.2 g of *sodium dihydrogen phosphate R* and 0.2 g of *potassium chloride R* in *water R*. Adjust to pH 7.2 using *1 M sodium hydroxide* or *1 M hydrochloric acid* and dilute to 1000 ml with *water R*.

Washing buffer. PBS containing 1 g/l of *polysorbate 20 R*.

Blocking reagent. PBS containing 1 g/l of *polysorbate 20 R* and 10 g/l of *bovine serum albumin R*.

Dilution buffer. PBS containing 1 g/l of *polysorbate 20 R* and 50 g/l of *bovine serum albumin R*.

Conjugate. Rabbit anti-human von Willebrand factor serum horseradish peroxidase conjugate. Use according to the manufacturer's instructions.

Substrate solution. Immediately before use, dissolve a tablet of *o*-phenylenediamine dihydrochloride and a tablet of urea hydrogen peroxide in 20 ml of *water R* or use a suitable volume of hydrogen peroxide. Protect from light.

Microtitre plates. Flat-bottomed polystyrene plates with surface properties optimised for enzyme immunoassay and high protein-binding capacity.

METHOD

Test solutions. Reconstitute the preparation to be examined as stated on the label. Dilute with dilution buffer to produce a solution containing approximately 1 IU of von Willebrand factor. Prepare 2 series of at least 3 further dilutions using dilution buffer.

Reference solutions. Reconstitute the reference preparation as directed. Dilute with dilution buffer to produce a solution containing approximately 1 IU of von Willebrand factor. Prepare 2 series of at least 3 further dilutions using dilution buffer.

Allow the solution of collagen to warm to room temperature. Dilute with collagen diluent to obtain a solution containing 30-75 µg/ml of collagen, mix gently to produce a uniform

suspension of collagen fibrils. Pipette 100 µl into each well of the microtitre plate. Cover the plate with plastic film and incubate at 37 °C overnight. Empty the wells of the collagen-coated plate by inverting and draining on a paper towel. Add 250 µl of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times. Add 250 µl of blocking reagent to each well, cover the plate with plastic film and incubate at 37 °C for 1 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µl of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Add 100 µl each of the test solutions or reference solutions to the wells. Add 100 µl of dilution buffer to a series of wells to serve as negative control. Cover the plate with plastic film and incubate at 37 °C for 2 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µl of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Prepare a suitable dilution of the conjugate (for example, a dilution factor of 1 to 4000) with PBS containing 5 g/l of *bovine serum albumin R* and add 100 µl to each well. Cover the plate with plastic film and incubate at 37 °C for 2 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µl of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Add 100 µl of substrate solution to each of the wells and incubate at room temperature for 20 min in the dark. Add 100 µl of *1 M hydrochloric acid* to each of the wells.

Measure the absorbance at 492 nm. Use the absorbance values to estimate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

The assay is invalid if the absorbances measured for the negative controls are greater than 0.05.

01/2008:20722

2.7.22. ASSAY OF HUMAN COAGULATION FACTOR XI

The principle of the assay is to measure the ability of a factor XI preparation to reduce the prolonged coagulation time of factor XI-deficient plasma. The reaction is accelerated by addition of a reagent containing phospholipid and a contact activator, e.g. kaolin, silica or ellagic acid. The potency is assessed by comparing the dose-response curve of the preparation to be examined to that of a reference preparation consisting of human normal plasma.

1 unit of factor XI is equal to the activity of 1 ml of human normal plasma. Human normal plasma is prepared by pooling plasma units from not fewer than 30 donors and stored at – 30 °C or lower.

Reconstitute separately the preparation to be examined and the reference preparation as stated on the label and use immediately. Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulphate R* (10 µg of protamine sulphate neutralises 1 IU of heparin). Predilute the preparation to be examined and the reference preparation in factor XI-deficient plasma (for example *plasma substrate R3*) to produce solutions containing 0.5-2.0 units/ml. Prepare at least 3 appropriate dilutions for each material, preferably in duplicate, using a suitable buffer solution (for example *imidazole buffer solution pH 7.3 R*) containing 10 g/l of bovine or human albumin. Use these dilutions immediately.

Use an apparatus suitable for measurement of coagulation times or perform the assay with incubation tubes maintained in a water bath at 37 °C. Place in each tube 0.1 ml of factor XI-deficient plasma (for example *plasma substrate R3*) and 0.1 ml of one of the dilutions of the reference preparation or of the preparation to be examined. Add to each tube 0.1 ml of a suitable Activated Partial Thromboplastin Time (APTT) reagent containing phospholipid and contact activator and incubate the mixture for a recommended time at 37 °C. To each tube, add 0.1 ml of a 3.7 g/l solution of *calcium chloride R* previously heated to 37 °C. Using a timer, measure the coagulation time, i.e. the interval between the moment of the addition of the calcium chloride and the first indication of the formation of fibrin. The volumes given above may be adapted to the APTT reagent and apparatus used. Calculate the potency using the usual statistical methods (for example, *5.3*).

01/2008:20723

2.7.23. NUMERATION OF CD34/CD45+ CELLS IN HAEMATOPOIETIC PRODUCTS

This chapter describes immunolabelling and analysis by flow cytometry (*2.7.24*) to determine the number of CD34/CD45+ cells contained in haematopoietic products. The determination is carried out by a single platform method using calibrated fluorospheres, after lysis of the sample red blood cells if necessary.

This method applies to all types of preparations and whole blood. However, its level of precision makes it particularly suitable for preparations containing very low percentages of CD34/CD45+ cells.

Graft quality assessment by CD34/CD45+ cell enumeration

A variety of studies have established that the 1-3 per cent of cells in the bone marrow that express the CD34 cell surface antigen are capable of reconstituting long-term, multilineage haematopoiesis after myeloablative therapy. CD34/CD45+ cells are also found in the peripheral circulation of normal individuals but are extremely rare (0.01-0.1 per cent). However, CD34/CD45+ cells may also be mobilised from marrow to the peripheral circulation in greater numbers by haematopoietic cytokines such as granulocyte colony-stimulating factor and/or chemotherapy.

The technique used for enumeration of CD34/CD45+ cells must meet the following requirements:

- high sensitivity, since haematopoietic stem cells are rare events;
- accuracy, to provide clinically relevant results;
- reproducibility, to provide clinically reliable results;
- speed, to provide real-time analysis.

Selection of parameters

The flow cytometry assay uses commercially available, directly conjugated fluorochrome-labelled monoclonal antibodies, routine staining and whole blood lysing procedures, and a gating strategy using light scatter and immunofluorescence analysis using a pan-CD45/CD34 monoclonal antibody combination.

It is possible to determine CD34/CD45+ cell viability by appropriate nucleic acid staining with a stain that does not cross the intact cell membrane (for example, with 7-aminoactinomycin D).

Selection of monoclonal antibodies

CD34 antibodies. Use class III CD34 antibodies that detect all glycosylation variants of the molecule (for example, clone 8G12 or 581). To detect rare events, use an antibody conjugated to the brightest fluorochrome excitable using an argon laser-based flow cytometer, for example phycoerythrin (PE).

CD45 antibodies. Pan-CD45 antibodies that detect all isoforms and all glycoforms of this structure are required. A CD45 antibody conjugated to fluorescein isothiocyanate (FITC) fluorochrome is generally used (for example, J33, HLe1, 2D1).

Isotypic or isoclonic controls. A negative control is analysed to detect any non-specific signal in the PE fluorescence region. If using an isotypic control (a monoclonal antibody to an irrelevant antigen of the same isotype as the CD34 antibody employed), the PE-conjugated isotype is combined with CD45-FITC (or PerCP). If using an isoclonic control, the unconjugated (in excess) and PE-conjugated CD34 identical monoclonal antibody is combined with conjugated CD45. Alternative combinations may be used.

Absolute count of CD34/CD45+

Calibrated fluorospheres. Depending on the technique used, the internal standard either consists of calibrated beads in suspension or is directly introduced into the associated tubes by the manufacturer.

The absolute count of the CD34/CD45+ cells per microlitre is calculated using the following expression:

$$\frac{A}{B} \times C$$

A = number of CD34/CD45+ cells counted;

B = number of fluorosphere singlets counted;

C = known fluorosphere concentration.

Gating strategies

The purpose of sequential gating is to select the population of interest and simultaneously minimise interference from debris and mature cells to which antibodies can bind non-specifically. If using a commercial kit, apply the gating recommended by the manufacturer. If using an in-house assay, it is preferable to apply a currently recommended strategy. A gating strategy that uses light scattering parameters and CD34/CD45 fluorescence will aid in the accurate identification and enumeration of CD34/CD45+ cells.

Number of events analysed

A sufficient number of events are analysed to maintain acceptable precision, for example not fewer than 100 CD34+ events and not fewer than 60 000 CD45+ events; the total number of cells counted may be greater if the percentage of CD34 is 0.1 per cent or less.

Specimen collection

Acid citrate dextrose (ACD) formula A is the anticoagulant used in apheresis procedures. This anticoagulant allows both an automated leucocyte count and flow cytometry evaluation to be performed on the same specimen. Edetic acid (EDTA) is the anticoagulant of choice for peripheral blood sampling.

Specimen transport

Transport conditions guarantee the physical and thermal safety of samples.

Specimen integrity and storage

Fresh (less than 24 h old) apheresis products, whole blood samples, umbilical cord blood specimens or bone marrow samples can be processed. Old specimens (more than 24 h old) and specimens that have been frozen and thawed are stained with a viability dye. On receipt, the temperature within the package is verified.

TECHNIQUE

Sample preparation

Ensure that the concentration of leucocytes is suitable prior to staining with monoclonal antibodies. If necessary, dilute the sample with medium that is compatible with the product to be tested and the lysing system. Record the dilution factor. It is recommended to perform the test with a negative control.

Flow cytometry analysis

Autostandardisation

For analysis of cells labelled with a commercially available kit, manufacturers have developed some quality tools for setting the flow cytometer. These settings are then automatically transferred on protocol analysis of samples. Specific fluorospheres are used to set the photomultiplier tube (PMT) on target values, compensation is set and the system is checked using a control preparation.

System settings

- *Discriminator/threshold*: the forward angle light scatter threshold is set to exclude debris (low forward scatter) but not small lymphocytes from the light-scatter plot.
- *PMT high voltage settings*: these must be consistent with cell-surface marker analysis and established within each laboratory so that negative and positive cell populations of moderate antigen density can be distinguished; PMT voltages are reviewed and adjusted periodically according to standardised laboratory procedures.
- *Compensation*: this must be acceptable for the colour spectra overlap (for example, FITC/PE) encountered in cell-surface marker analysis; colour compensation is analysed and adjusted according to standardised laboratory procedures.
- *Flow rate*: this must be consistent with routine cell-surface marker analysis.
- *Gating regions*: the gating regions established for the CD34/CD45 samples are maintained unaltered for the analysis of the negative region.

Calculation of absolute number of CD34/CD45+ cells

The absolute number of CD34/CD45+ cells is calculated using the following expression:

$$n \times D \times V$$

n = total number of CD34/CD45+ cells per microlitre;

D = dilution factor;

V = volume of the product to be tested, in microlitres.

Results are reported as both the percentage of CD34/CD45+ cells and the absolute number per microlitre. They may also be reported as the absolute number per kilogram of recipient body mass, where this is possible.

01/2008:20724

2.7.24. FLOW CYTOMETRY

Flow cytometry consists of a multiparametric analysis of optical properties of individual particles in a fluidic system.

Cells or particles in suspension are individually distributed into a linear array (stream), which flows through a detection device. Solid tissues have to be reduced to a single-cell suspension to be analysed.

The spectrum of parameters measurable by flow cytometry includes volume and morphological complexity of cells or cell-like structures, cell pigments, DNA content, RNA content, proteins, cell surface markers, intracellular markers, enzymatic activity, pH, membrane and fluidity.

It is possible to collect 2 morphological parameters plus 1 or more fluorescence signals per single cell. The multiparametric analysis allows the definition of cell populations by their phenotype.

APPARATUS

Focusing, magnifying, and choice of light source are optimised to allow the automatic detection and measurement of morphological differences and staining patterns. Flow cytofluorimetric analysis meets the following criteria:

- choice of light source depending on the parameters to be analysed;
- adjustment of instrument settings depending on the cell type to be analysed (for example, cell cultures, leucocytes, platelets, bacteria, spermatozoa, yeast) and the analysis to be performed (for example, phenotyping, cell cycle, apoptosis, cytokines, membrane fluidity, fluorescent protein).

Flow cytometry is characterised by the automated quantification of set parameters for a high number of single cells during each analysis session. For example, 100 000 particles or more (practically unlimited) are analysed one after the other, typically in about 1 min. The detection limit is as low as 100 fluorescent molecules per cell.

A flow cytometer apparatus has 5 main components:

- a fluidic system and a flow cell;
- a light source;
- a detection and Analogue to Digital Conversion (ADC) system;
- an amplification system;
- a computer provided with software for analysis of the signals.

FLUIDIC SYSTEM AND FLOW CELL

The single cell is exposed to the light source and detected in the flow cell. The fluidic system carries the suspended cells individually from the sample tube to the laser intercept point. To achieve this, the sample stream is drawn out to a very thin fluid thread by a sheath fluid in the flow cell (hydrodynamic focusing). The light beam is focused in an elliptical shape, by 2 confocal lenses, into the flow cell channel through which the cells pass. The flow rate must be constant during routine cell surface marker analysis and must ensure a suitable distance between the cells to allow counting.

LIGHT SOURCES

Commonly used light sources are:

- lamps (mercury, xenon);
- high power water-cooled lasers (argon, krypton, dye laser);
- low power air-cooled lasers (argon (488 nm), red helium-neon (633 nm), green helium-neon, helium-cadmium (UV));
- diode lasers (blue, green, red, violet).

SIGNAL DETECTION

When a particle passes across the light beam, it scatters some of the light in all directions. Fluorescent dyes, when added to the particle, give off their own light (fluorescence), which is also radiated in all directions. 2 types of signals may thereby be generated:

- scatter of light;
- fluorescence emission.

The instrument's light detectors collect some of this scattered and fluorescent light and produce electronic signals proportional to the amount of light collected.

Scatter. 2 parameters of light scattering are measured:

- the amount scattered mainly forward (forward scatter (FS))
- the amount scattered at 90° from the direction of the light beam (side scatter (SS)).

Forward scatter correlates with the cell volume while side scatter is influenced by parameters such as the shape of the nucleus, the amount and type of cytoplasmic granules or the membrane roughness, and correlates with the morphological complexity of the cell, so that the higher the SS intensity, the higher the cell complexity. As a function of the morphological characteristics of cells, scatter signals will always be generated during a flow analysis; they are defined as intrinsic parameters.

Fluorescence. Depending on the type and number of light sources, when a cell passes through the sensing area, it will emit fluorescent light. Fluorescence signals are generated from fluorescent dyes naturally present in the cells (for example, co-enzymes, chlorophyll, seaweed pigments) and/or from fluorescent probes taken up by the cells when stained for the analysis of specific characteristics (for example, fluorescent antibodies, nucleic acid dyes, pH probes, calcium probes, fluorescent proteins). Nowadays, there is a large number and a wide range of different types of fluorescent probes available. The optical filters must be adapted to the fluorochromes used and changed if necessary. Each fluorescent probe is characterised by its excitation spectrum and its emission spectrum. They are chosen depending on the nature of the excitation source and the detection system, and according to the specific purpose of the analysis.

SIGNAL MANAGEMENT AND ANALOGUE TO DIGITAL CONVERSION

Scatter and fluorescence signals emitted by cells when passing across the laser beam are sorted and addressed to their detectors using optical filters. The detectors are transducers (photomultiplier tubes (PMTs)) that convert light signals radiated from the cells into voltage pulses.

The process of counting each pulse in the appropriate channel is known as Analogue to Digital Conversion (ADC). The process is finally shown as a frequency histogram.

Amplification. Voltage pulses need to be amplified for optimal visualisation. The amplification process accentuates the differences between cell signals, and consequently increases the resolution among cell populations of different characteristics (for example, the differentiation of viable from non-viable cells, or non-specific fluorescence from antigen-specific fluorescence after staining with a fluorescent monoclonal antibody).

There are 2 methods of amplification: linear or logarithmic; the choice between the 2 types is made for every single signal according to the morphological characteristics of the cells and the staining reagents used (for example, fluorescent monoclonal antibodies, nucleic acid dyes).

Linear amplification, which enhances the differences among strong pulses, is used with those parameters that generate high intensity signals, for example:

– cell scatters;

– fluorescence from nucleic acid dyes for cell cycle studies.

Logarithmic amplification, in contrast, is for weak pulses and parameters or analysis conditions that may generate both weak and strong pulses, for example:

– cell antigens;

– scatter from platelets, bacteria, yeast;

– fluorescence from nucleic acid dyes for apoptosis studies.

Compensation of fluorescence signals. Each fluorescent dye has an absorption wavelength spectrum and a higher emission wavelength spectrum. When using 2 or more fluorescent probes simultaneously for staining cells (for example, 4-antigen immunophenotyping), the fluorochromes emission spectra may overlap. As a consequence, each fluorescence detector will sense its own specific fluorescent light and a variable amount of light emitted by the other fluorescent probes. This results in signal over-evaluation and poor separation of the cell populations.

The solution is in the use of an electronic matrix that allows the selective subtraction of the interfering signals from each fluorescence signal after detector sensing (fluorescence compensation).

Fluorescence compensation requires the use of fluorescence calibrators, preferably positive cell samples stained with the fluorochromes of interest, combined in a manner equivalent to that for the antibody used for the analysis.

SIGNAL PLOTTING AND DISPLAY

After amplification and compensation, the signals are plotted in 2 or 3 dimensions. Histograms show the signal intensities versus the cell counts for a given parameter. Cytograms, in which each dot represents a cell, result from the combination of 2 signal intensities (dual-parameter dot plots). The type and number of plots and signal combinations are chosen on the basis of the specimens and dyes used. When analysing acquired data, the flow cytometry software can also generate other kinds of graphs (such as overlays, surface plots, tomograms, contour plots, density plots, overlay plots). Statistical data such as mean fluorescent intensities (and their shifts in time or their dependence on cell function) can also be used.

DATA ANALYSIS

Different kinds of cell populations may be present inside the cell suspensions to be analysed, some of which are unwanted (such as dead cells, debris or macro-aggregates), or simply not relevant for the analysis (for example, granulocytes when studying lymphocytes). This depends on the cell sample type (whole blood, bone marrow, cell cultures, biological fluids, cell suspensions from solid tissues) and on the handling procedures (for example, staining methods, lysis, fixation, cryopreservation, thawing, paraffin-embedded tissue preparation).

As a consequence, not all the signals generated during a flow cytometry analysis belong to the cells to be studied. 2 strategies are adopted to exclude unwanted and irrelevant cell signals.

The 1st is used during data acquisition. It is a noise threshold, applied to 1 (or more) significant parameter(s), set to acquire only the cells with signal intensities higher than the pre-defined discrimination value for that parameter. Due to its characteristics of a strong signal with a low grade of interference, forward scatter is the parameter most often used as discriminator.

The 2nd, applied during data analysis, consists of the use of gating regions to restrict the analysis only to signals from those populations that satisfy given morphological and expression profile characteristics. 2 types of logical gating are commonly used. The 1st is the morphological gate. The cell populations are identified using their morphological signals (FS and SS). A region gate is drawn around the population of interest (for example, lymphocytes, viable cells) then the fluorescence plots are gated into the selected region. The 2nd is the fluorescence-based gate. The cell population of interest is identified on the basis of the expression intensity of an antigen or a dye, then a gate region is drawn around it. Afterwards the fluorescence plots are gated into the selected region.

The analysis software allows the creation of multiple gate regions, using a sequential logic order. This feature is especially useful when studying rare cell populations or for sorting purposes.

CONTROLS

Internal control. The system's optical alignment must be validated before analysis using adapted fluorospheres and the optimum fluidic stability is checked. The data obtained are reported and allow the periodical review of control values against the mean performance value. A positive control is highly desirable to prove that the test antibody is functional and to allow the proper setting of the flow cytometer. The positive control must include samples known to be positive for the marker of interest.

External control. To ensure reliability in the data obtained or to check inter-laboratory reproducibility, participation in a proficiency testing study is recommended.

01/2008:20727

2.7.27. FLOCCULATION VALUE (Lf) OF DIPHTHERIA AND TETANUS TOXINS AND TOXOIDS (RAMON ASSAY)

The content of toxin or toxoid in a sample can be expressed as a flocculation value (Lf) using the Ramon assay. In this assay, antitoxin is added in increasing concentrations to a series of tubes containing a constant amount of toxin or toxoid. At the equivalence point of toxin/toxoid and antitoxin, flocculation occurs in 1 or more tubes. The first tube in which flocculation occurs is used to determine the Lf value of the sample.

The Lf value of a toxin or toxoid is determined by the number of units of antitoxin that, when mixed with the sample, produces an optimally flocculating mixture (Ramon assay).

Practical experience has shown that the results of the calibration of antitoxins in International Units (IU), for example by comparison to international antitoxin standards, depends on the immunochemical method used. For this reason, antitoxins used for the Ramon assay must be directly calibrated against the *international biological reference reagents for diphtheria or tetanus toxoid for flocculation tests*, using the principles described below. The concentration thus determined may be indicated in Lf-equivalents per millilitre (Lf-eq./ml).

By definition, 1 Lf is the quantity of toxin or toxoid that flocculates in the shortest time with 1 Lf-eq. of specific antitoxin.

A range of volumes of the reference standard of antitoxin adjusted to a concentration of 100 Lf-eq./ml is dispensed into a series of, for example, 7 cm × 1 cm flocculation tubes. A sufficient quantity of a 9 g/l solution of *sodium chloride R* is added to each tube to give a constant total

volume of, for example, 1 ml. The test sample is diluted to give an expected concentration of approximately 50 Lf/ml, and, for example, 1 ml aliquots of this dilution are dispensed into each of the tubes containing antitoxin. The tubes are properly mixed by shaking, then placed in a water-bath at a constant temperature between 30 °C and 52 °C, and observed at regular intervals for the first appearance of floccules. This may require the use of a magnifying lens and strong illumination.

The first and the second mixtures to flocculate are recorded as well as the time taken for the first flocculation to appear. 2 tubes may flocculate simultaneously.

The first tube to flocculate is the one that contains the amount of antitoxin closest in equivalence to the amount of antigen in the sample. The antitoxin content of this tube can be used to calculate the Lf value of the sample. If 2 tubes flocculate at the same time, the mean from the tubes are given as the result.

The time taken for the first tube to flocculate (Kf) is a useful indicator of the quality of the antigen. If at a given temperature and concentration of toxoid and antitoxin the Kf value is increased compared with normal, this indicates that the antigen has been damaged. The Kf value may also change with the quality of the antitoxin used.

Example

Tube	A	B	C	D	E	F
Antitoxin added (Lf-eq.)	40	45	50	55	60	65
Antitoxin added (ml)	0.40	0.45	0.50	0.55	0.60	0.65
Saline added (ml)	0.60	0.55	0.50	0.45	0.40	0.35
Diluted sample added	1.0	1.0	1.0	1.0	1.0	1.0

If in this example the first tube to flocculate is tube C then the Lf value of the diluted sample is 50 Lf/ml. However, if the first tube to flocculate is tube A or tube F this does not indicate equivalence at that level. It would be necessary to perform a repeat test using either a different dilution of test sample or selecting a different range of doses of reference antitoxin.

More precision can be obtained by making allowance for the sequence of flocculation after the first tube. Thus, in the example quoted, if the second tube to flocculate had been tube D, the final value for the diluted sample would be 52, whereas if the second tube to flocculate was tube B, the final value would be 48. The test may be performed in duplicate with slightly different dilutions of the test sample.

If there is no indication of the expected Lf value of the sample available, it is advisable to obtain a rough estimate by use of a wider range of antitoxin content in the tubes before proceeding to the final test.

Example

Tube	A	B	C	D	E	F
Antitoxin content (Lf-eq.)	20	30	45	70	100	150

The level of toxin or toxoid and antitoxin concentration in the test may be varied, but this will markedly affect the flocculation time, so that at very low levels the test will take too long, whilst at a high concentration the onset of flocculation may be so rapid as to make it difficult to distinguish the first and second tubes to flocculate.

Assay of low concentrations by blend flocculation

For very low concentrations, it is preferable to measure toxin or toxoid by the method of blend flocculation. This involves comparison of the Lf value of a known toxin or toxoid and that of a mixture of the sample with that toxin or toxoid.

When a toxin or toxoid with a known Lf value and a toxin or toxoid with an unknown Lf value are flocculated together, the mixture will flocculate as the sum of their values if they are homogeneous. If non-homogenous toxins or toxoids are mixed they will produce an aberrant pattern with 2 flocculation maxima.

01/2008:20728

2.7.28. COLONY-FORMING CELL ASSAY FOR HUMAN HAEMATOPOIETIC PROGENITOR CELLS

The haematopoietic system represents a continuum of cells whose phenotype and properties change as they progress from stem cells to differentiated cells.

Haematopoietic progenitor cells (HPCs) are capable of forming colonies or ‘cell clusters’ in cultures grown in semi-solid media and are said to be ‘clonogenic’. The determination of the number of colony-forming cells (CFCs) in a cellular product is an indicator of the functional capacity of the progenitor cells and is a predictor of haematopoietic reconstitution. The measured number of CFCs correlates with the minimum number of progenitors present in the sample.

CELL-SURFACE MARKERS

The capacity of colony-forming cells to give rise to haematopoietic colonies *in vitro* and/or to reconstitute the haematopoietic system has been correlated with the expression of specific cell-surface antigens. The expression of the membrane antigen CD34 is an accepted marker for most of the haematopoietic progenitors and stem cells.

COLONY ASSAY SPECIFICITY

Colony-forming cells are identified with a nomenclature based on the lineages of mature cells present in the colony (for example, CFU-Mix, CFU-GEMM, CFU-GM, CFU-G, CFU-M, BFU-E, CFU-E, CFU-Meg) and are a population of progenitors able to give rise to colonies containing one or more lineages of haematopoietic cells. No or low capacity for self-renewal has been ascribed to this population of human HPCs compared with the most immature stem cells.

The amount and type of growth factors supplied during the culture modulate the type and size of colonies that will be formed.

Greater specificity on the general class of HPCs and on their relative proliferative potential is provided by the time required to differentiate *in vitro* into mature cells. The time required by post-natal colony-forming cells to give rise to a colony formed of mature cells *in vitro* is 10-14 days.

QUALITY ASSURANCE FOR A CFC ASSAY

It is paramount for the overall quality of the colony-forming cell assay to apply a strictly standardised approach. It is therefore recommended to carry out intra- and inter-laboratory validations. The source of the materials, including reagents, growth factors and disposables, is identified.

The main factors affecting variability in the CFC assay are the number of cells plated and the identification of colonies. Up to 15 per cent intra-laboratory variability may be observed for the same test. If it is necessary to evaluate the number of colony-forming cells in a purified cell population, it is possible to use a limiting dilution approach where the number of wells positive for cell proliferation is measured with an automated system.

The other main source of variability stems from the use of undefined materials (for example, foetal bovine serum or bovine serum albumin) in the CFC assay. These products derive from pools of source materials and provide a non-specific stimulation of cellular proliferation. However, it is not uncommon to have batches with particular characteristics that selectively stimulate the proliferation of specific haematopoietic lineages.

Finally, a low level of endotoxins (less than 0.01 IU/ml or less than 0.01 IU/mg) in all the materials used for the clonogenic assay is advisable, as higher levels result first in a progressive skewing of the haematopoietic lineages expression in the cultures, and afterwards in a more general inhibition of cell proliferation and clonogenesis.

CFC CLONOGENIC ASSAY

The CFC assay is based on the capacity of progenitor cells to form a colony when plated in a semi-solid medium or in a gel in the presence of specific growth factors. Different types of semi-solid media may be used (for example, methylcellulose, collagen, agar and plasma-clot) depending on the desired readout. Commercially available media usually give more reproducible results.

MATERIALS

A validation is performed at least for the following critical materials.

Growth factors. Both multilineage (such as Kit-ligand or stem cell factor (SCF), interleukin-3, granulocyte-macrophage colony-stimulating factor (GM-CSF)) and lineage-specific (erythropoietin, granulocyte colony-stimulating factor (G-CSF)) growth factors are required to obtain the highest number of colonies from a cell suspension containing a mixed population of HPCs.

Other media components. Media may be supplemented by serum (notably by foetal bovine serum) and/or albumin.

CELL CULTURE

Cells. The sample placed in culture must be representative of the cellular product injected. Cell suspensions are required for this assay. In the case of bone marrow aspirates, such suspensions can be obtained by forcing the bone marrow through a sieve or through progressively smaller calibre needles. Repeated passages through a 21-gauge needle are usually sufficient to disperse cell clusters into a cell suspension.

PLATING AND SCORING

The cells diluted in the culture medium are mixed in the semi-solid medium. It is common to plate 1 ml of the mixture in an untreated sterile Petri dish (Ø 35 mm).

Because of the viscosity of the medium, the solution cannot be plated with air displacement pipettes and the use of syringes equipped with large bore (≤ 18-gauge) needles is required.

The number of cells to be plated depends on the HPC concentration in the sample to be tested. So that no colony is derived from 2 different HPCs, the number of cells plated must allow between 40 and 80 colonies per plate (Ø 35 mm) to be counted. The 'target' number of colonies per plate may be obtained either from the percentage of CD34+ (or concentration of CD34+ cells/ml) determined by flow cytometry (*2.7.24*) or from different dilutions of the cell suspension (usually 2 concentrations are tested).

The plates are incubated in aerobic conditions with a carbon dioxide concentration of 5 per cent, at 37 °C in a humid (saturated) atmosphere for 10-14 days, and the number of colonies is then scored under an inverted microscope. Care must be taken when manipulating the dishes containing the colonies as the methylcellulose-based medium is viscous but not jellified. An inclined plate will result in mixed and 'comet'-shaped colonies making the scoring likely to be incorrect.

IDENTIFICATION OF THE COLONIES

The size and structure of the colonies depend on the type of mature cells that are their constituents. 50 cells per colony is usually considered a minimum. The presence of haemoglobinised cells identifies progenitors of the erythroid lineage. As the amount of mature cells for each lineage largely depends on the growth factors added to the cultures, performing differentiated counts is not recommended unless otherwise prescribed.

EXPRESSION OF THE RESULTS

The results of CFC culture are usually expressed as the arithmetic mean of the number of colonies counted in at least 3 plates in the test. The mean number of colonies is then related to 10^4 or 10^5 viable nucleated cells placed in culture.

01/2008:20729

2.7.29. NUCLEATED CELL COUNT AND VIABILITY

The determination of the quality of cell suspensions requires accurate measurements of both cell concentration and percentage of viable cells. These data are essential to the decision-making process for preparing cellular products and for maintaining optimum culture conditions. The cell count may be expressed as the number of cells per volume of cell suspension and the cell viability as the number of viable cells per volume of cell suspension. The cell-count procedure may be performed manually (haemocytometer) or with an automated apparatus (for example, particle counter, flow cytometer). Other methods than that described below may be used.

CELL NUMBER

MANUAL COUNTING

Description of the apparatus and test principle. The following materials are required:

- a haemocytometer: a specialised microscope counting chamber available in different designs. It consists of a thick slide and a coverslip mounted to delimit a chamber with a specific volume for each design. The thick slide of the various haemocytometers consists of counting chambers separated by deep groves to avoid cross-filling. The counting chamber is etched in the glass and contains a grid which is specific for each model;
- a light microscope - low power 10× to 40× magnification;
- pipettes of a suitable volume range.

The haemocytometer is used to quantify the number of cells in a given solution by calculation of the cell concentration per millilitre (C) using the following expression:

$$a \times 10^n \times d$$

a = number of cells counted;

d = dilution factor (where applicable);

n = factor varying with the volume of the haemocytometer chamber.

It is possible to distinguish between mixed cell populations provided they differ in size or pigmentation (for example, leukocytes and erythrocytes).

Preparation of the counting chamber and analysis. Mount the coverslip (slightly moistened on the edges) on the slide. Move the coverslip back and forth over the slide, pressing slightly on the sides. Prepare a suitable dilution of the cell suspension in isotonic buffer or in haemolysis buffer.

Add an appropriate volume of the dilution to the counting chamber. The liquid is added to the border of the coverslip and is drained inside the chamber by capillarity. Carefully place the haemocytometer under the microscope and focus. Count the cells in a zone of the grid. Calculate the cell concentration in the diluted and original samples.

To increase the accuracy of the measurement, it is important to respect the following basic precautions:

- use only suitably thickened coverslips;
- wherever possible, count more than 100 cells (if necessary, count more areas);
- where cell clustering is detected (i.e. the cell suspension is not monocellular), resuspend the cells before sampling and count again;
- avoid underfilling or overflowing the chamber, otherwise the volume will no longer be accurate.

AUTOMATED COUNTING METHODS

Particle counters based on conductivity variation. Electronic particle counting devices measure the size and number of particles in a solution.

Particle counters are calibrated before use with a solution of particles of known concentration and size. To allow the counting of larger particles, tubes fitted with differently calibrated orifices are available. These apparatuses do not allow the discrimination between dead and live cells. As cell debris may also generate pulses that may cause errors, counters are also fitted with a threshold control allowing only larger particles to be counted.

The apparatus must be qualified for the counting of cellular products (in terms of linearity, accuracy, etc.).

Particle counters based on flow cytometry (*2.7.24*). The flow cytometer is calibrated with reference particles of known concentration and size to give an absolute cell number per volume. However, a calibrating solution is no longer necessary in instruments using 2 electrodes inserted in the sampling chamber where the fixed size of the sampling chamber and distance between the 2 electrodes allow the measurement of the content of a fixed volume. This type of instrument rarely needs to be calibrated after the initial setting.

VIABILITY

This section applies to cell staining by viability dyes and manual or automated analysis, under a light microscope or by flow cytometry, of a cell suspension in order to determine the percentage of viable cells.

Depending on the type of cells and the method used, the results may differ.

MANUAL DYE-EXCLUSION METHOD

Test principle. This test is based on the exclusion of the dye from viable cells whereas dead or damaged cells absorb the dye and are coloured. It provides information on the cytoplasmic membrane integrity but its results do not necessarily reflect cell functionality. Recently trypsinised or thawed viable cells may have leaky membranes, causing them to absorb the dye.

Dye. Trypan blue is the stain most commonly used to distinguish between viable and non-viable cells, but other suitable dyes such as erythrosin B or nigrosin may also be used. It is an acid dye (M_r 961), an anion with 4 sulphonate groups that can easily bind to proteins; therefore the protein concentration of the preparation to be tested must be as low as possible.

Test conditions. Dye fixation is strongly influenced by pH, within a range of 6.6 to 7.6. Fixation is optimal at pH 7.5. The other conditions, such as the dye concentration and the staining time are validated.

Storage conditions of the dye: Generally a 0.4 or 0.5 per cent trypan blue solution in sterile phosphate-buffered saline is used. Store protected from light and air.

Test preparation and analysis. Stain the cell suspension at the required dilution (usually in phosphate-buffered saline) with, for example, a trypan blue solution having a final concentration of 0.1 to 0.2 per cent. Mix gently. Incubate for not more than 2-4 min at room temperature. Mix gently and place a suitable volume in a counting chamber. Count without delay.

Determine the percentage of viable cells from the ratio of the number of unstained cells to the total number of cells under a light microscope, considering all stained cells as dead cells. Viability (V) is calculated as a percentage using the following expression:

$$\frac{n}{N} \times 100$$

n = number of unstained (viable) cells;

N = total number of cells (stained and unstained).

It is essential that the incubation time be not more than 4 min as the number of stained cells may increase significantly afterwards. For a new determination, it may therefore be necessary to prepare a new test.

AUTOMATED METHODS

Flow cytometry

Test principle. The test is based on the ability of certain dyes to cross damaged membranes and bind to DNA by intercalating between bases so that dead cells may fluoresce and be detected by flow cytometry (*2.7.24*). Non-viable cells are evaluated and discriminated by focusing on positive staining whereas viable cells remain unstained. This analysis is generally performed with 7-aminoactinomycin D (7-AAD) or propidium iodide (PI) but other suitable dyes may also be used.

Dye. 7-AAD and PI are given as examples of membrane-impermeants that may be used as viability dyes.

7-AAD is an analogue of actinomycin D that contains a substituted amino group at position 7 of the chromophore. It intercalates between cytosine and guanine DNA bases. The spectral properties of 7-AAD make this molecule particularly suitable for flow-cytometry analysis. The maximum absorption of the 7-AAD/DNA complex is situated in the green spectral region and is thus suitable for an argon laser-equipped cytometer (excitation wavelength of 488 nm). The deep red fluorescence emission of the 7-AAD

viability dye (635 nm to 675 nm) eases the use of the probe in combination with fluorescein isothiocyanate (FITC) and phycoerythrin (PE)-conjugated antibodies, because in contrast to PI, the 7-AAD/DNA complex shows minimal overlap with FITC and PE.

PI binds to double-stranded DNA by intercalating between bases with little or no sequence preference and with a stoichiometry of 1 dye molecule per 4-5 DNA base pairs. Once the dye is bound to nucleic acids, its fluorescence is enhanced 20- to 30-fold, the fluorescence excitation maximum is shifted around 30-40 nm towards the red and the fluorescence emission maximum (615 nm) is shifted around 15 nm towards the blue. Although its absorptivity is quite low, PI exhibits a sufficiently large Stokes shift to allow simultaneous detection of nucleic acids and fluorescein-labelled antibodies, provided that the suitable optical filters are used.

Storage conditions of nucleic acid dye solution: 5 ± 3 °C.

Test preparation and analysis. In the case of haematopoietic cells, the dye may be added after CD45 labelling to obtain a better separation of cells from debris and platelets with a side scatter (SS)/CD45+ gating region. The incubation conditions of the cell suspension with the dye are validated previously.

Incubation is performed at room temperature protected from light. Where necessary, lysis of red blood cells is performed using, for example, ammonium chloride. If not, add buffer alone.

Percentages of viable cells are directly given by the flow cytometer and deduced from the analysis of positive cells (dead cells) in the SS/7-AAD or SS/PI cytogram (dot plots).

Positive controls may consist of stabilised cells (dead cells) mixed with fresh viable cells at a target value.

Digital imaging of stained cells. Digital imaging allows the automation of dye-exclusion methods. The cell suspension and viability-dye solution are directly mixed by a machine. The system, which allows sample aspiration, reagent handling, and subsequent instrument cleaning is fully automated. Once the cellular suspension has been aspirated and mixed with the dye solution, it is pumped to the flow cell for imaging. The stained cell suspension is aspirated through a chamber where stroboscopic light allows a camera to photograph the flowing cells. The images are digitalised and the number of dead or live cells counted by the software.

2.8. METHODS IN PHARMACOGNOSY

01/2008:20801

2.8.1. ASH INSOLUBLE IN HYDROCHLORIC ACID

Ash insoluble in hydrochloric acid is the residue obtained after extracting the sulphated or total ash with hydrochloric acid, calculated with reference to 100 g of drug.

To the crucible containing the residue from the determination of sulphated or total ash, add 15 ml of *water R* and 10 ml of *hydrochloric acid R*, cover with a watch-glass, boil the mixture gently for 10 min and allow to cool. Filter through an ashless filter, wash the residue with hot *water R* until the filtrate is neutral, dry, ignite to dull redness, allow to cool in a desiccator and weigh. Reheat until the difference between 2 consecutive weighings is not more than 1 mg.

01/2008:20802

2.8.2. FOREIGN MATTER

Herbal drugs should be free from moulds, insects and other animal contamination.

Foreign matter is material consisting of any or all of the following:

1) *Foreign organs*: matter coming from the source plant but not defined as the drug,

2) *Foreign elements*: matter not coming from the source plant and either of vegetable or mineral origin.

DETERMINATION OF FOREIGN MATTER

Weigh 100 g to 500 g of the substance to be examined, or the minimum quantity prescribed in the monograph, and spread it out in a thin layer. Examine for foreign matter by inspection with the unaided eye or by use of a lens (6 ×). Separate foreign matter and weigh it and calculate the percentage present.

01/2008:20803

2.8.3. STOMATA AND STOMATAL INDEX

STOMATA

There are several types of stomata (see Figure 2.8.3.-1), distinguished by the form and arrangement of the surrounding cells:

(1) The *anomocytic* (irregular-celled) type: the stoma is surrounded by a varying number of cells in no way differing from those of the epidermis generally,

(2) The *anisocytic* (unequal-celled) type: the stoma is usually surrounded by 3 subsidiary cells, of which one is markedly smaller than the others,

(3) The *diacytic* (cross-celled) type: the stoma is accompanied by 2 subsidiary cells, whose common wall is at right angles to the guard cells,

(4) The *paracytic* (parallel-celled) type: the stoma has on each side one or more subsidiary cells parallel to the long axis of the pore and guard cells.

STOMATAL INDEX

$$\text{Stomatal Index} = \frac{100 \times S}{E + S}$$

S = the number of stomata in a given area of leaf,

E = the number of epidermal cells (including trichomes) in the same area of leaf.

For each sample of leaf, make not fewer than 10 determinations and calculate the mean.

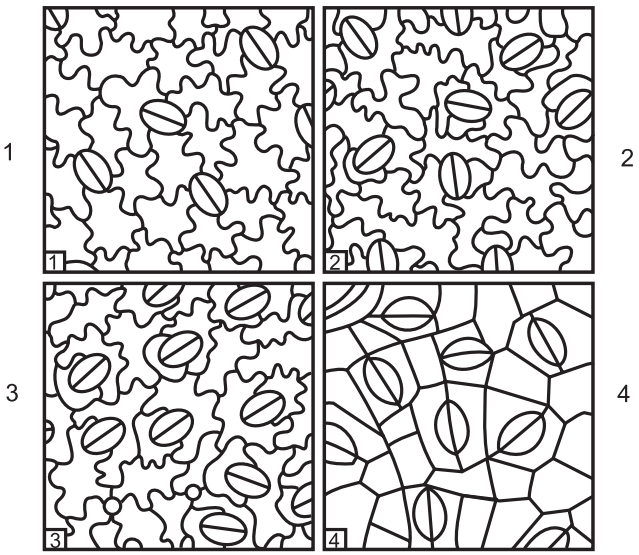

Figure 2.8.3.-1

01/2008:20804

2.8.4. SWELLING INDEX

The swelling index is the volume in millilitres occupied by 1 gram of a drug, including any adhering mucilage, after it has swollen in an aqueous liquid for 4 h.

In a 25 ml ground-glass stoppered cylinder graduated over a height of 125 ± 5 mm in 0.5 ml divisions, place 1.0 g of the drug, whole or of the degree of comminution prescribed in the monograph. Unless otherwise prescribed, moisten the drug with 1.0 ml of *alcohol R*, add 25 ml of *water R* and close the cylinder. Shake vigorously every 10 min for 1 h. Allow to stand for 3 h. At 90 min after the beginning of the test, release any large volumes of liquid retained in the layer of the drug and any particles of the drug floating at the surface of the liquid by rotating the cylinder about a vertical axis. Measure the volume occupied by the drug, including any adhering mucilage. Carry out 3 tests at the same time.

The swelling index is given by the mean of the 3 tests.

01/2008:20805

2.8.5. WATER IN ESSENTIAL OILS

Mix 10 drops of the essential oil with 1 ml of *carbon disulphide R*. The solution remains clear on standing.

01/2008:20806

2.8.6. FOREIGN ESTERS IN ESSENTIAL OILS

Heat 1 ml of the essential oil for 2 min on a water-bath with 3.0 ml of a freshly prepared 100 g/l solution of *potassium hydroxide R* in *alcohol R*. No crystals are formed within 30 min, even after cooling.

01/2008:20807

2.8.7. FATTY OILS AND RESINIFIED ESSENTIAL OILS IN ESSENTIAL OILS

Allow 1 drop of the essential oil to fall onto filter paper. The drop evaporates completely within 24 h without leaving any translucent or greasy spot.

01/2008:20808

2.8.8. ODOUR AND TASTE OF ESSENTIAL OILS

Mix 3 drops of the essential oil with 5 ml of *90 per cent V/V alcohol R* and stir in 10 g of powdered *sucrose R*. The odour and taste are similar to that of the plant or parts of the plant from which the essential oil has been obtained.

01/2008:20809

2.8.9. RESIDUE ON EVAPORATION OF ESSENTIAL OILS

The residue on evaporation of an essential oil is the percentage by mass of the oil which remains after evaporation on a water-bath under the conditions specified below.

Apparatus. The apparatus (see Figure 2.8.9.-1) consists of:

- Water-bath with a cover having holes of 70 mm diameter,
- Evaporating dish of heat-resistant glass which is inert to the contents,
- Desiccator.

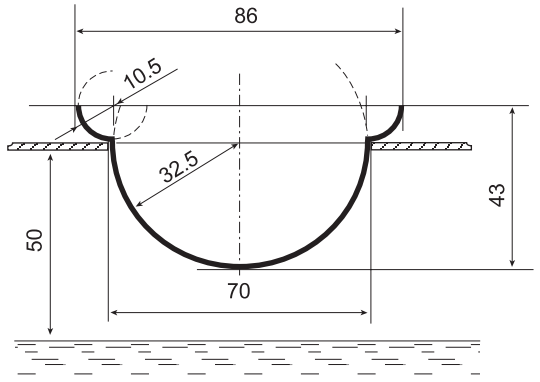

Figure 2.8.9.-1.

Dimensions in millimetres

Method. Weigh the evaporating dish after having heated it on the water-bath for 1 h and cooled it in the desiccator. Weigh into the evaporating dish 5.00 g of the essential oil, unless otherwise prescribed. Heat the oil on the vigorously boiling water-bath in a draught-free atmosphere for the prescribed time. Allow to cool in the desiccator and weigh. During the test, the level of water in the bath is maintained about 50 mm beneath the level of the cover.

01/2008:20810

2.8.10. SOLUBILITY IN ALCOHOL OF ESSENTIAL OILS

Place 1.0 ml of the essential oil in a 25 ml or 30 ml glass-stoppered cylinder. Place in a constant temperature device, maintained at a temperature of 20 ± 0.2 °C. Using a burette of at least 20 ml capacity, add the alcohol of the strength prescribed in the monograph by increments of 0.1 ml until solution is complete and then continue adding by increments of 0.5 ml to a total of 20 ml, shaking frequently and vigorously. Record the volume of alcohol added when a clear solution has been obtained and, if the solution becomes cloudy or opalescent before 20 ml of alcohol has been added, record the volume added when the cloudiness or opalescence appears and, where applicable, the volume added when the cloudiness or opalescence disappears.

If a clear solution has not been obtained when 20 ml of alcohol of the prescribed strength has been added, repeat the test using the next highest concentration of alcohol.

An essential oil is said to be "soluble in *n* volumes and more of alcohol of given strength *t*" when the clear solution in *n* volumes remains clear when compared with the undiluted oil after further addition of alcohol of the same strength up to a total of 20 volumes of alcohol.

An essential oil is said to be "soluble in *n* volumes of alcohol of given strength *t*, becoming cloudy when diluted" when the clear solution in *n* volumes becomes cloudy in n_1 volumes (n_1 less than 20) and stays so after further gradual addition of alcohol of the same strength up to a total of 20 volumes of alcohol.

An essential oil is said to be "soluble in *n* volumes of alcohol of given strength *t* with cloudiness between n_1 and n_2 volumes" when the clear solution in *n* volumes becomes cloudy in n_1 volumes (n_1 less than 20) and stays so after further gradual addition of alcohol of the same strength up to a total of n_2 volumes of alcohol and then becomes clear (n_2 less than 20).

An essential oil is said to be "soluble with opalescence" when the alcoholic solution shows a bluish tinge, similar to that of a standard of opalescence freshly prepared as follows: mix 0.5 ml of *silver nitrate solution R2* and 0.05 ml of *nitric acid R*; add 50 ml of a 12 mg/l solution of *sodium chloride R*; mix and allow to stand protected from light for 5 min.

01/2008:20811

2.8.11. ASSAY OF 1,8-CINEOLE IN ESSENTIAL OILS

Weigh 3.00 g of the oil, recently dried with *anhydrous sodium sulphate R*, into a dry test-tube and add 2.10 g of melted *cresol R*. Place the tube in the apparatus for the determination of freezing point (*2.2.18*) and allow to cool, stirring continuously. When crystallisation takes place there is a small rise in temperature. Note the highest temperature reached (t_1).

Remelt the mixture on a water-bath at a temperature that does not exceed t_1 by more than 5 °C and place the tube in the apparatus, maintained at a temperature 5 °C below t_1. When crystallisation takes place, or when the

temperature of the mixture has fallen 3 °C below t_1, stir continuously. Note the highest temperature at which the mixture crystallises (t_2). Repeat the operation until 2 highest values obtained for t_2 do not differ by more than 0.2 °C. If supercooling occurs, induce crystallisation by adding a small crystal of the complex consisting of 3.00 g of *cineole R* and 2.10 g of melted *cresol R*. If t_2 is below 27.4 °C, repeat the determination after the addition of 5.10 g of the complex.

The content of cineole corresponding to the highest temperature observed (t_2) is given in Table 2.8.11.-1. If 5.10 g of the complex has been added, calculate the cineole content per cent *m/m* from the expression:

$$2\,(A - 50)$$

where A is the value found in Table 2.8.11.-1.

The content of cineole, corresponding to the highest temperature observed (t_2), is obtained, where necessary, by interpolation.

Table 2.8.11.-1

t_2 °C	cineole per cent *m/m*	t_2 °C	cineole per cent *m/m*	t_2 °C	cineole per cent *m/m*	t_2 °C	cineole per cent *m/m*
24	45.5	32	56.0	40	67.0	48	82.0

2.8.12. DETERMINATION OF ESSENTIAL OILS IN HERBAL DRUGS

The determination of essential oils in herbal drugs is carried out by steam distillation in a special apparatus in the conditions described below. The distillate is collected in the graduated tube, using xylene to take up the essential oil; the aqueous phase is automatically returned to the distillation flask.

Apparatus. The apparatus comprises the following parts:

(a) a suitable round-bottomed flask with a short, ground-glass neck having an internal diameter of about 29 mm at the wide end;

(b) a condenser assembly (see Figure 2.8.12.-1) that closely fits the flask, the different parts being fused into one piece; the glass used has a low coefficient of expansion:

- the stopper *K′* is vented and the tube *K* has an orifice of diameter about 1 mm that coincides with the vent; the wide end of the tube *K* is of ground-glass and has an internal diameter of 10 mm;
- a pear-shaped swelling, *J*, of 3 ml capacity;
- the tube *JL* is graduated in 0.01 ml;
- the bulb-shaped swelling *L* has a capacity of about 2 ml;
- *M* is a three-way tap;
- the junction *B* is at a level 20 mm higher than the uppermost graduation;

(c) a suitable heating device, allowing a fine control;

(d) a vertical support with a horizontal ring covered with insulating material.

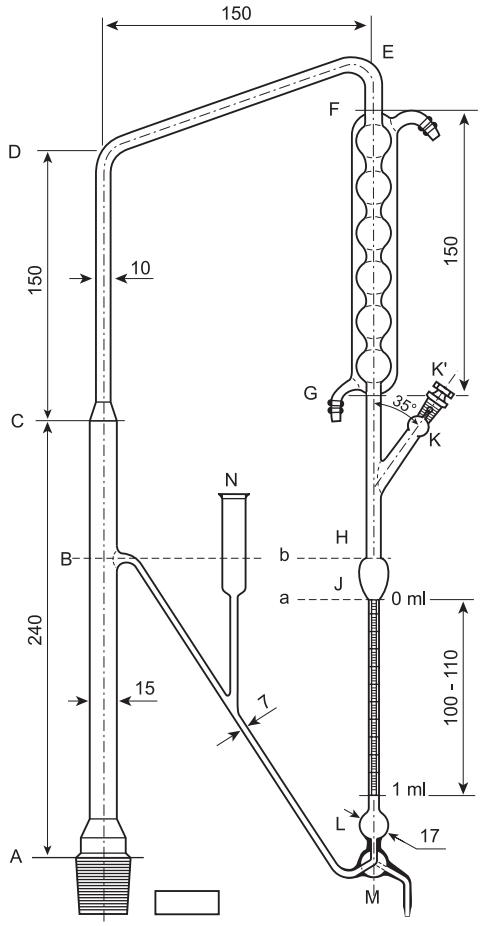

Figure 2.8.12.-1. - *Apparatus for the determination of essential oils in herbal drugs*

Dimensions in millimetres

Method. Use a thoroughly cleaned apparatus. Carry out the assay according to the nature of the drug to be examined. Place the prescribed volume of distillation liquid in the flask, add a few pieces of porous porcelain and attach the condenser assembly. Introduce *water R* through the filling funnel *N* until it is at the level *B*. Remove the stopper *K′* and introduce the prescribed quantity of *xylene R*, using a pipette with its tip at the bottom of the tube *K*. Replace the stopper *K′* and ensure that the orifice coincides with the vent. Heat the liquid in the flask to boiling and adjust the distillation rate to 2-3 ml/min, unless otherwise prescribed.

To determine the rate of distillation, during distillation lower the level of the water by means of the three-way tap until the meniscus is at the level of the lower mark (a) (see Figure 2.8.12.-2). Close the tap and measure the time taken for the liquid to reach the upper mark (b). Open the tap and continue the distillation, modifying the heat to regulate the distillation rate. Distil for 30 min. Stop the heating and after at least 10 min read off the volume of xylene in the graduated tube.

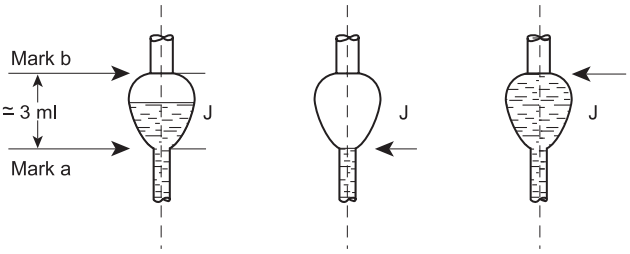

Figure 2.8.12.-2

Introduce into the flask the prescribed quantity of the drug and continue the distillation as described above for the time and at the rate prescribed. Stop the heating and after 10 min read the volume of liquid collected in the graduated tube and subtract the volume of xylene previously noted. The difference represents the quantity of essential oil in the mass of the drug taken. Calculate the result as millilitres per kilogram of drug.

When the essential oil is to be used for other analytical purposes, the water-free mixture of xylene and essential oil may be recovered as follows: remove the stopper *K′* and introduce 0.1 ml of a 1 g/l solution of *sodium fluoresceinate R* and 0.5 ml of *water R*. Lower the mixture of xylene and essential oil into the bulb-shaped swelling *L* by means of the three-way tap, allow to stand for 5 min and lower the mixture slowly until it just reaches the level of the tap *M*. Open the tap anti-clockwise so that the water flows out of the connecting tube *BM*. Wash the tube with *acetone R* and with a little *toluene R* introduced through the filling funnel *N*. Turn the tap anti-clockwise in order to recover the mixture of xylene and essential oil in an appropriate flask.

01/2008:20813

2.8.13. PESTICIDE RESIDUES

Definition. For the purposes of the Pharmacopoeia, a pesticide is any substance or mixture of substances intended for preventing, destroying or controlling any pest, unwanted species of plants or animals causing harm during or otherwise interfering with the production, processing, storage, transport or marketing of herbal drugs. The item includes substances intended for use as growth-regulators, defoliants or desiccants and any substance applied to crops either before or after harvest to protect the commodity from deterioration during storage and transport.

Limits. Unless otherwise indicated in the monograph, the drug to be examined at least complies with the limits indicated in Table 2.8.13.-1. The limits applying to pesticides that are not listed in the table and whose presence is suspected for any reason comply with the limits set by European Community directives 76/895 and 90/642, including their annexes and successive updates. Limits for pesticides that are not listed in Table 2.8.13.-1 nor in EC directives are calculated using the following expression:

$$\frac{ADI \times M}{MDD \times 100}$$

ADI = acceptable daily intake, as published by FAO-WHO, in milligrams per kilogram of body mass,

M = body mass in kilograms (60 kg),

MDD = daily dose of the drug, in kilograms.

If the drug is intended for the preparation of extracts, tinctures or other pharmaceutical forms whose preparation method modifies the content of pesticides in the finished product, the limits are calculated using the following expression:

$$\frac{ADI \times M \times E}{MDD \times 100}$$

E = extraction factor of the method of preparation, determined experimentally.

Higher limits can also be authorised, in exceptional cases, especially when a plant requires a particular cultivation method or has a metabolism or a structure that gives rise to a higher than normal content of pesticides.

The competent authority may grant total or partial exemption from the test when the complete history (nature and quantity of the pesticides used, date of each treatment during cultivation and after the harvest) of the treatment of the batch is known and can be checked precisely.

Sampling

Method. For containers up to 1 kg, take one sample from the total content, thoroughly mixed, sufficient for the tests. For containers between 1 kg and 5 kg, take three samples, equal in volume, from the upper, middle and lower parts of the container, each being sufficient to carry out the tests. Thoroughly mix the samples and take from the mixture an amount sufficient to carry out the tests. For containers of more than 5 kg, take three samples, each of at least 250 g from the upper, middle and lower parts of the container. Thoroughly mix the samples and take from the mixture an amount sufficient to carry out the tests.

Size of sampling. If the number (*n*) of containers is three or fewer, take samples from each container as indicated above under Method. If the number of containers is more than three, take $\sqrt{n} + 1$ samples from containers as indicated under Method, rounding up to the nearest unit if necessary.

The samples are to be analysed immediately to avoid possible degradation of the residues. If this is not possible, the samples are stored in airtight containers suitable for food contact, at a temperature below 0 °C, protected from light.

Reagents. All reagents and solvents are free from any contaminants, especially pesticides, that might interfere with the analysis. It is often necessary to use special quality solvents or, if this is not possible, solvents that have recently been re-distilled in an apparatus made entirely of glass. In any case, suitable blank tests must be carried out.

Apparatus. Clean the apparatus and especially glassware to ensure that they are free from pesticides, for example, soak for at least 16 h in a solution of phosphate-free detergent, rinse with large quantities of *distilled water R* and wash with acetone and hexane or heptane.

Qualitative and quantitative analysis of pesticide residues. The analytical procedures used are validated according to the regulations in force. In particular, they satisfy the following criteria:

- the chosen method, especially the purification steps, are suitable for the combination pesticide residue/substance to be analysed, and not susceptible to interference from co-extractives; the limits of detection and quantification are measured for each pesticide-matrix combination to be analysed,
- between 70 per cent to 110 per cent of each pesticide is recovered,
- the repeatability of the method is not less than the values indicated in Table 2.8.13.-2,

– the reproducibility of the method is not less than the values indicated in Table 2.8.13.-2,

– the concentration of test and reference solutions and the setting of the apparatus are such that a linear response is obtained from the analytical detector.

Table 2.8.13.-1

Substance	Limit (mg/kg)
Alachlor	0.02
Aldrin and Dieldrin (sum of)	0.05
Azinphos-methyl	1.0
Bromopropylate	3.0
Chlordane (sum of *cis*-, *trans* - and Oxythlordane)	0.05
Chlorfenvinphos	0.5
Chlorpyrifos	0.2
Chlorpyrifos-methyl	0.1
Cypermethrin (and isomers)	1.0
DDT (sum of *p,p'*-DDT, *o,p'*-DDT, *p,p'*-DDE and *p,p'*-TDE)	1.0
Deltamethrin	0.5
Diazinon	0.5
Dichlorvos	1.0
Dithiocarbamates (as CS_2)	2.0
Endosulfan (sum of isomers and Endosulfan sulphate)	3.0
Endrin	0.05
Ethion	2.0
Fenitrothion	0.5
Fenvalerate	1.5
Fonofos	0.05
Heptachlor (sum of Heptachlor and Heptachlorepoxide)	0.05
Hexachlorobenzene	0.1
Hexachlorocyclohexane isomers (other than γ)	0.3
Lindane (γ-Hexachlorocyclohexane)	0.6
Malathion	1.0
Methidathion	0.2
Parathion	0.5
Parathion-methyl	0.2
Permethrin	1.0
Phosalone	0.1
Piperonyl butoxide	3.0
Pirimiphos-methyl	4.0
Pyrethrins (sum of)	3.0
Quintozene (sum of quintozene, pentachloroaniline and methyl pentachlorophenyl sulphide)	1.0

Table 2.8.13.-2

Concentration of the pesticide (mg/kg)	Repeatability (difference, ± mg/kg)	Reproducibility (difference, ± mg/kg)
0.010	0.005	0.01
0.100	0.025	0.05
1.000	0.125	0.25

The following section is published for information.

Test for pesticides

ORGANOCHLORINE, ORGANOPHOSPHORUS AND PYRETHROID INSECTICIDES

The following methods may be used, in connection with the general method above. Depending on the substance being examined, it may be necessary to modify, sometimes extensively, the procedure described hereafter. In any case, it may be necessary to use, in addition, another column with a different polarity or another detection method (mass spectrometry...) or a different method (immunochemical methods...) to confirm the results obtained.

This procedure is valid only for the analysis of samples of herbal drugs containing less than 15 per cent of water. Samples with a higher content of water may be dried, provided it has been shown that the drying procedure does not affect significantly the pesticide content.

1. EXTRACTION

To 10 g of the substance being examined, coarsely powdered, add 100 ml of *acetone R* and allow to stand for 20 min. Add 1 ml of a solution containing 1.8 µg/ml of *carbophenothion R* in *toluene R*. Homogenise using a high-speed blender for 3 min. Filter and wash the filter cake with two quantities, each of 25 ml, of *acetone R*. Combine the filtrate and the washings and heat using a rotary evaporator at a temperature not exceeding 40 °C until the solvent has almost completely evaporated. To the residue add a few millilitres of *toluene R* and heat again until the acetone is completely removed. Dissolve the residue in 8 ml of *toluene R*. Filter through a membrane filter (45 µm), rinse the flask and the filter with *toluene R* and dilute to 10.0 ml with the same solvent (solution A).

2. PURIFICATION

2.1. Organochlorine, organophosphorus and pyrethroid insecticides. Examine by size-exclusion chromatography (*2.2.30*).

The chromatographic procedure may be carried out using:

– a stainless steel column 0.30 m long and 7.8 mm in internal diameter packed with *styrene-divinylbenzene copolymer R* (5 µm),

– as mobile phase *toluene R* at a flow rate of 1 ml/min.

Performance of the column. Inject 100 µl of a solution containing 0.5 g/l of *methyl red R* and 0.5 g/l of *oracet blue 2R R* in *toluene R* and proceed with the chromatography. The column is not suitable unless the colour of the eluate changes from orange to blue at an elution volume of about 10.3 ml. If necessary calibrate the column, using a solution containing, in *toluene R*, at a suitable concentration, the insecticide to be analysed with the lowest molecular mass (for example, dichlorvos) and that with the highest molecular mass (for example, deltamethrin). Determine which fraction of the eluate contains both insecticides.

Purification of the test solution. Inject a suitable volume of solution A (100 µl to 500 µl) and proceed with the chromatography. Collect the fraction as determined above (solution B). Organophosphorus insecticides are usually eluted between 8.8 ml and 10.9 ml. Organochlorine and pyrethroid insecticides are usually eluted between 8.5 ml and 10.3 ml.

2.2. Organochlorine and pyrethroid insecticides. In a chromatography column, 0.10 m long and 5 mm in internal diameter, introduce a piece of defatted cotton and 0.5 g of silica gel treated as follows: heat *silica gel for chromatography R* in an oven at 150 °C for at least 4 h.

Allow to cool and add dropwise a quantity of *water R* corresponding to 1.5 per cent of the mass of silica gel used; shake vigorously until agglomerates have disappeared and continue shaking for 2 h using a mechanical shaker. Condition the column using 1.5 ml of *hexane R*. Prepacked columns containing about 0.50 g of a suitable silica gel may also be used provided they are previously validated.

Concentrate solution B in a current of *helium for chromatography R* or *oxygen-free nitrogen R* almost to dryness and dilute to a suitable volume with *toluene R* (200 µl to 1 ml according to the volume injected in the preparation of solution B). Transfer quantitatively onto the column and proceed with the chromatography using 1.8 ml of *toluene R* as the mobile phase. Collect the eluate (solution C).

3. QUANTITATIVE ANALYSIS

3.1. Organophosphorus insecticides. Examine by gas chromatography (*2.2.28*), using *carbophenothion R* as internal standard. It may be necessary to use a second internal stan-dard to identify possible interference with the peak corresponding to carbophenothion.

Test solution. Concentrate solution B in a current of *helium for chromatography R* almost to dryness and dilute to 100 µl with *toluene R*.

Reference solution. Prepare at least three solutions in *toluene R* containing the insecticides to be determined and carbophenothion at concentrations suitable for plotting a calibration curve.

The chromatographic procedure may be carried out using:

– a fused-silica column 30 m long and 0.32 mm in internal diameter the internal wall of which is covered with a layer 0.25 µm thick of *poly(dimethyl)siloxane R*,

– *hydrogen for chromatography R* as the carrier gas. Other gases such as *helium for chromatography R* or *nitrogen for chromatography R* may also be used provided the chromatography is suitably validated.

– a phosphorus-nitrogen flame-ionisation detector or a atomic emission spectrometry detector,

maintaining the temperature of the column at 80 °C for 1 min, then raising it at a rate of 30 °C/min to 150 °C, maintaining at 150 °C for 3 min, then raising the temperature at a rate of 4 °C/min to 280 °C and maintaining at this temperature for 1 min, and maintaining the temperature of the injector port at 250 °C and that of the detector at 275 °C. Inject the chosen volume of each solution. When the chromatograms are recorded in the prescribed conditions, the relative retention times are approximately those listed in Table 2.8.13.-3. Calculate the content of each insecticide from the peak areas and the concentrations of the solutions.

3.2. Organochlorine and pyrethroid insecticides. Examine by gas chromatography (*2.2.28*), using carbophenothion as the internal standard. It may be necessary to use a second internal standard to identify possible interference with the peak corresponding to carbophenothion

Test solution. Concentrate solution C in a current of *helium for chromatography R* or *oxygen-free nitrogen R* almost to dryness and dilute to 500 µl with *toluene R*.

Reference solution. Prepare at least three solutions in *toluene R* containing the insecticides to be determined and carbophenothion at concentrations suitable for plotting a calibration curve.

Table 2.8.13.-3

Substance	Relative retention times
Dichlorvos	0.20
Fonofos	0.50
Diazinon	0.52
Parathion-methyl	0.59
Chlorpyrifos-methyl	0.60
Pirimiphos-methyl	0.66
Malathion	0.67
Parathion	0.69
Chlorpyrifos	0.70
Methidathion	0.78
Ethion	0.96
Carbophenothion	1.00
Azinphos-methyl	1.17
Phosalon	1.18

The chromatographic procedure may be carried out using:

– a fused silica column 30 m long and 0.32 mm in internal diameter the internal wall of which is covered with a layer 0.25 µm thick of *poly(dimethyl)(diphenyl)siloxane R*,

– *hydrogen for chromatography R* as the carrier gas. Other gases such as *helium for chromatography R* or *nitrogen for chromatography R* may also be used, provided the chromatography is suitably validated,

– an electron-capture detector,

– a device allowing direct cold on-column injection,

maintaining the temperature of the column at 80 °C for 1 min, then raising it at a rate of 30 °C/min to 150 °C, maintaining at 150 °C for 3 min, then raising the temperature at a rate of 4 °C/min to 280 °C and maintaining at this temperature for 1 min, and maintaining the temperature of the injector port at 250 °C and that of the detector at 275 °C. Inject the chosen volume of each solution. When the chromatograms are recorded in the prescribed conditions, the relative retention times are approximately those listed in Table 2.8.13.-4. Calculate the content of each insecticide from the peak areas and the concentrations of the solutions.

Table 2.8.13.-4

Substance	Relative rentention times
α-Hexachlorocyclohexane	0.44
Hexachlorobenzene	0.45
β-Hexachlorocyclohexane	0.49
Lindane	0.49
δ-Hexachlorocyclohexane	0.54
ϵ-Hexachlorocyclohexane	0.56
Heptachlor	0.61
Aldrin	0.68
cis-Heptachlor-epoxide	0.76
o,p'-DDE	0.81
α-Endosulfan	0.82
Dieldrin	0.87
p,p'-DDE	0.87
o,p'-DDD	0.89
Endrin	0.91

Substance	Relative rentention times
β-Endosulfan	0.92
o,p'-DDT	0.95
Carbophenothion	1.00
p,p'-DDT	1.02
cis-Permethrin	1.29
trans-Permethrin	1.31
Cypermethrin*	1.40
Fenvalerate*	1.47 and 1.49
Deltamethrin	1.54

* The substance shows several peaks.

2.8.14. DETERMINATION OF TANNINS IN HERBAL DRUGS

Carry out all the extraction and dilution operations protected from light.

In the case of a herbal drug or a dry extract, to the stated amount of the powdered drug (180) (*2.9.12*) or the extract in a 250 ml round-bottomed flask add 150 ml of *water R*. Heat on a water-bath for 30 min. Cool under running water and transfer quantitatively to a 250 ml volumetric flask. Rinse the round-bottomed flask and collect the washings in the volumetric flask, then dilute to 250.0 ml with *water R*. Allow the solids to settle and filter the liquid through a filter paper 125 mm in diameter. Discard the first 50 ml of the filtrate.

In the case of a liquid extract or a tincture, dilute the stated amount of the liquid extract or tincture to 250.0 ml with *water R*. Filter the mixture through a filter paper 125 mm in diameter. Discard the first 50 ml of the filtrate.

Total polyphenols. Dilute 5.0 ml of the filtrate to 25.0 ml with *water R*. Mix 2.0 ml of this solution with 1.0 ml of *phosphomolybdotungstic reagent R* and 10.0 ml of *water R* and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm (A_1), using *water R* as the compensation liquid.

Polyphenols not adsorbed by hide powder. To 10.0 ml of the filtrate, add 0.10 g of *hide powder CRS* and shake vigorously for 60 min. Filter and dilute 5.0 ml of the filtrate to 25.0 ml with *water R*. Mix 2.0 ml of this solution with 1.0 ml of *phosphomolybdotungstic reagent R* and 10.0 ml of *water R* and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm (A_2), using *water R* as the compensation liquid.

Standard. Dissolve immediately before use 50.0 mg of *pyrogallol R* in *water R* and dilute to 100.0 ml with the same solvent. Dilute 5.0 ml of the solution to 100.0 ml with *water R*. Mix 2.0 ml of this solution with 1.0 ml of *phosphomolybdotungstic reagent R* and 10.0 ml of *water R* and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm (A_3), using *water R* as the compensation liquid.

Calculate the percentage content of tannins expressed as pyrogallol from the expression:

$$\frac{62.5\,(A_1 - A_2)\,m_2}{A_3 \times m_1}$$

m_1 = mass of the sample to be examined, in grams,

m_2 = mass of pyrogallol, in grams.

01/2008:20815

2.8.15. BITTERNESS VALUE

The bitterness value is the reciprocal of the dilution of a compound, a liquid or an extract that still has a bitter taste. It is determined by comparison with quinine hydrochloride, the bitterness value of which is set at 200 000.

Determination of the correction factor

A taste panel comprising at least 6 persons is recommended. The mouth must be rinsed with *water R* before tasting.

To correct for individual differences in tasting bitterness amongst the panel members it is necessary to determine a correction factor for each panel member.

Stock solution. Dissolve 0.100 g of *quinine hydrochloride R* in *water R* and dilute to 100.0 ml with the same solvent. Dilute 1.0 ml of this solution to 100.0 ml with *water R*.

Reference solutions. Prepare a series of dilutions by placing in a first tube 3.6 ml of the stock solution and increasing the volume by 0.2 ml in each subsequent tube to a total of 5.8 ml; dilute the contents of each tube to 10.0 ml with *water R*.

Determine as follows the dilution with the lowest concentration that still has a bitter taste. Take 10.0 ml of the weakest solution into the mouth and pass it from side to side over the back of the tongue for 30 s. If the solution is not found to be bitter, spit it out and wait for 1 min. Rinse the mouth with *water R*. After 10 min, use the next dilution in order of increasing concentration.

Calculate the correction factor *k* for each panel member from the expression:

$$k = \frac{n}{5.00}$$

n = number of millilitres of the stock solution in the dilution of lowest concentration that is judged to be bitter.

Persons who are unable to taste any bitterness when using the reference solution prepared from 5.8 ml of stock solution have to be excluded from the panel.

Sample preparation

If necessary, reduce the sample to a powder (710) (*2.9.12*). To 1.0 g of sample add 100 ml of boiling *water R*. Heat on a water-bath for 30 min, stirring continuously. Allow to cool and dilute to 100 ml with *water R*. Shake vigorously and filter, discarding the first 2 ml of the filtrate. The filtrate is labelled C-1 and has a dilution factor (DF) of 100.

If liquids have to be examined, 1 ml of the liquid is diluted with a suitable solvent to 100 ml and designated C-1.

Determination of the bitterness value

Test solutions:

10.0 ml of C-1 is diluted with *water R* to 100 ml: C-2	(DF = 1000)
10.0 ml of C-2 is diluted with *water R* to 100 ml: C-3	(DF = 10 000)
20.0 ml of C-3 is diluted with *water R* to 100 ml: C-3A	(DF = 50 000)
10.0 ml of C-3 is diluted with *water R* to 100 ml: C-4	(DF = 100 000)

Starting with dilution C-4 each panel member determines the dilution which still has a bitter taste. This solution is designated D. Note the DF of solution D is Y.

Starting with solution D prepare the following sequence of dilutions:

Solution D (ml)	1.2	1.5	2.0	3.0	6.0	8.0
water R (ml)	8.8	8.5	8.0	7.0	4.0	2.0

Determine the number of millilitres of solution D which, when diluted to 10.0 ml with *water R*, still has a bitter taste (X).

Calculate the bitterness value for each panel member from the expression:

$$\left(\frac{\mathrm{Y} \times k}{\mathrm{X} \times 0.1}\right)$$

Calculate the bitterness value of the sample to be examined as the average value for all panel members.

01/2008:20816

2.8.16. DRY RESIDUE OF EXTRACTS

In a flat-bottomed dish about 50 mm in diameter and about 30 mm in height, introduce rapidly 2.00 g or 2.0 ml of the extract to be examined. Evaporate to dryness on a water-bath and dry in an oven at 100-105 °C for 3 h. Allow to cool in a desiccator over *diphosphorus pentoxide R* or *anhydrous silica gel R* and weigh. Calculate the result as a mass percentage or in grams per litre.

01/2008:20817

2.8.17. LOSS ON DRYING OF EXTRACTS

In a flat-bottomed dish about 50 mm in diameter and about 30 mm in height, weigh rapidly 0.50 g of the extract to be examined, finely powdered. Dry in an oven at 100-105 °C for 3 h. Allow to cool in a desiccator over *diphosphorus pentoxide R* or *anhydrous silica gel R* and weigh. Calculate the result as a mass percentage.

01/2008:20818

2.8.18. DETERMINATION OF AFLATOXIN B_1 IN HERBAL DRUGS

CAUTION: aflatoxins are very toxic and carcinogenic. Perform manipulations under an extraction hood whenever possible. Take particular precautions, such as use of a glove box, when toxins are in dry form because of their electrostatic properties and the tendency to disperse through the working areas. Decontamination procedures for laboratory wastes of aflatoxins were developed by the International Agency for Research on Cancer (IARC).

Aflatoxins are naturally occurring mycotoxins produced mainly by *Aspergillus flavus* and *Aspergillus parasiticus*. These fungi are common and widespread in nature and are most often found when certain grains are grown under conditions of stress such as drought. The mould occurs in soil, decaying vegetation, hay, and grains undergoing microbial spoilage, and invades all types of organic substrates whenever and wherever the conditions are favourable for its growth. Favourable conditions include high moisture content and high temperature. At least 13 different types of aflatoxin are produced in nature and most of these are known to be highly toxic and carcinogenic. Aflatoxin B_1 is considered the most toxic. Herbal drugs that are subject to contamination by aflatoxins are tested by a validated method.

Unless otherwise indicated in the monograph, herbal drugs contain not more than 2 µg/kg of aflatoxin B_1. The competent authority may also require compliance with a limit of 4 µg/kg for the sum of aflatoxins B_1, B_2, G_1 and G_2.

The method described below is cited as an example of a method that has been shown to be suitable for devil's claw root, ginger and senna pods. Its suitability for other herbal drugs must be demonstrated or another validated method used.

METHOD

Liquid chromatography (*2.2.29*).

Aflatoxins are subject to light degradation. Carry out the determination protected from daylight by using UV-absorbing foil on windows in combination with subdued light, or curtains or blinds in combination with artificial light (fluorescent tubes are acceptable). Protect aflatoxin-containing solutions from daylight.

Rinse glassware before use with a 10 per cent *V/V* solution of *sulphuric acid R* and then rinse carefully with *distilled water R* until no more acid is present.

Test solution. Use an immunoaffinity column containing antibodies against aflatoxin B_1 with a capacity of not less than 100 ng of aflatoxin B_1 and which gives a recovery of not less than 80 per cent when a solution of 5 ng of aflatoxin B_1 in a mixture of 12.5 ml of *methanol R* and 87.5 ml of *water R* is passed through. Allow the immunoaffinity column to reach room temperature. To 5.00 g of the powdered drug (500) (*2.9.12*) add 100 ml of a mixture of 30 volumes of *water R* and 70 volumes of *methanol R* and extract by sonication for 30 min. Filter through folded filter paper. Pipette 10.0 ml of the clear filtrate into a 150 ml conical flask. Add 70 ml of *water R*. Pass 40 ml through the immunoaffinity column at a flow rate of 3 ml/min (not exceeding 5 ml/min). Wash the column with 2 volumes, each of 10 ml, of *water R* at a flow rate not exceeding 5 ml/min and dry by applying a slight vacuum for 5-10 s or by passing air through the immunoaffinity column by means of a syringe for 10 s. Apply 0.5 ml of *methanol R* to the column and allow to pass through by gravity. Collect the eluate in a 5 ml volumetric flask. After 1 min, apply a 2nd portion of 0.5 ml of *methanol R*. After a further 1 min, apply a 3rd portion of 0.5 ml of *methanol R*. Collect most of the applied elution solvent by pressing air through or applying vacuum to the column. Dilute to 5 ml with *water R* and shake well. If the solution is clear it can be used directly for analysis. Otherwise, pass it through a disposable filter unit prior to injection. Use a disposable filter unit (e.g. 0.45 µm pore size polytetrafluoroethylene filter) that has been shown not to cause loss of aflatoxin by retention.

Aflatoxin B_1 primary stock solution. Dissolve *aflatoxin B_1 R* in a mixture of 2 volumes of *acetonitrile R* and 98 volumes of *toluene R* to give a 10 µg/ml solution. To determine the exact concentration of aflatoxin B_1 in the stock solution, record the absorption curve (*2.2.25*) between 330 nm and 370 nm in quartz cells.

Calculate the aflatoxin B_1 mass concentration, in micrograms per millilitre, using the following expression:

$$\frac{A \times M \times 100}{\varepsilon \times l}$$

A = absorbance determined at the maximum of the absorption curve;

M = molar mass of aflatoxin B_1 (312 g/mol);

ϵ = molar absorptivity of aflatoxin B_1 in the toluene-acetonitrile mixture (1930 m^2/mol);

l = optical path length of the cell (1 cm).

Aflatoxin B_1 secondary stock solution. Prepare a secondary stock solution containing 100 ng/ml aflatoxin B_1 by diluting aflatoxin B_1 primary stock solution with a mixture of 2 volumes of *acetonitrile R* and 98 volumes of *toluene R*. Wrap the flask tightly in aluminium foil and store it below 4 °C. Before use, do not remove the aluminium foil until the contents have reached room temperature. If the solution has to be stored for a long period (for example, 1 month), weigh the flask and record the mass before and after each use of the solution.

Aflatoxin B_1 standard solutions. Place the volumes of aflatoxin secondary stock solution indicated in Table 2.8.18.-1 in separate 250 ml volumetric flasks. Pass a stream of nitrogen through at room temperature until the solvent has just evaporated. To each flask, add 75 ml of *methanol R*, allow the aflatoxin B_1 to dissolve and dilute to 250 ml with *water R*.

Table 2.8.18.-1. – *Aflatoxin B_1 standard solutions*

Standard solution	Volume of secondary stock solution (µl)	Final concentration of standard solution (ng/ml)
1	125	0.05
2	250	0.1
3	500	0.2
4	750	0.3
5	1000	0.4

Calibration curve. Prepare the calibration curve using aflatoxin B_1 standard solutions 1 to 5, which cover a range equivalent to 1-8 µg/kg of aflatoxin B_1 in the herbal drug. Check the plot for linearity. If the content of aflatoxin B_1 in the sample to be examined is outside of the calibration range, the test solution must be diluted to an aflatoxin content that is appropriate for the established calibration curve.

Column:

– *size*: l = 0.25 m, Ø = 4.6 mm;

– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase:

– *mobile phase A* (for post-column derivatisation with photochemical reactor or pyridinium bromide): *acetonitrile R, methanol R, water R* (2:3:6 *V/V/V*);

– *mobile phase B* (for post-column derivatisation with electrochemically derived bromine): add 0.12 g of *potassium bromide R* and 350 µl of *dilute nitric acid R1* per litre of mobile phase A.

Flow rate: 1 ml/min.

Detection: fluorescence detector with a 360 nm excitation filter and a 420 nm cut-off emission filter, or equivalent. Recommended settings for adjustable detectors are 365 nm (excitation wavelength) and 435 nm (emission wavelength).

Injection: 500 µl.

Post-column derivatisation with pyridinium hydrobromide perbromide (PBPB):

– pulseless pump;

– T-piece with zero dead volume;

– polytetrafluoroethylene reaction tube, l = 0.45 m, Ø = 0.5 mm;

– mobile phase A;

– post-column derivatisation reagent: dissolve 50 mg of *pyridinium hydrobromide perbromide R* in 1000 ml of *water R* (store protected from light and use within 4 days);

– flow rate of the derivatisation reagent: 0.4 ml/min.

Post-column derivatisation with photochemical reactor (PHRED)

– reactor unit with one 254 nm low pressure mercury UV bulb (minimum 8 W);

– polished support plate;

– knitted reactor coil: polytetrafluoroethylene tubing knitted tightly around the UV bulb, l = 25 m, Ø = 0.25 mm, nominal void volume 1.25 ml;

– exposure time: 2 min;

– mobile phase A.

Post-column derivatisation with electrochemically generated bromine (KOBRA):

– KOBRA-cell: electrochemical cell that generates a reactive form of bromine for derivatisation of aflatoxins, resulting in enhanced fluorescence; available from various commercial suppliers;

– Derivation direct-current supply in series with the KOBRA-cell, providing a constant current of about 100 µA;

– polytetrafluoroethylene reaction tube, l = 0.12 m, Ø = 0.25 mm;

– mobile phase B.

Elution order: aflatoxin G_2, aflatoxin G_1, aflatoxin B_2, aflatoxin B_1.

Calculation: calculate the calibration curve $y = ax + b$, with aflatoxin B_1 concentration (ng/ml) on the x-axis and the signal (S) on the y-axis. The aflatoxin B_1 concentration (C) in a measured solution is equal to $\frac{S-b}{a}$.

Calculate the aflatoxin B_1 content of the herbal drug, in nanograms per gram, using the following expression:

$$\frac{V_1 \times V_2 \times C}{m \times V_i}$$

m = mass of the herbal drug taken for analysis, in grams;

V_1 = volume of the solvent used for extraction, in millilitres;

V_i = aliquot taken for immunoaffinity clean-up, in millilitres;

V_2 = final volume of solution after elution from the immunoaffinity column and dilution, in millilitres;

C = measured aflatoxin B_1 concentration of the test solution, in nanograms per millilitre.

The presence of aflatoxin B_1 may be confirmed by recording the chromatogram without post-column derivatisation, which leads to a large decrease (greater than 10-fold) in the response due to aflatoxin B_1.

01/2008:20820

2.8.20. HERBAL DRUGS: SAMPLING AND SAMPLE PREPARATION

In order to reduce the effect of sampling in qualitative and quantitative analysis, it is necessary to ensure that the composition of the sample used is representative of the batch of material being examined. The following procedures are the minimum considered applicable for herbal drugs. *NOTE: other procedures may be used if they can be demonstrated to produce representative batch samples.*

BULK SAMPLE

Where external examination of containers, markings and labels of a batch indicate that it can be considered to be homogeneous, sample the number of randomly selected containers indicated below. Where a batch cannot be considered to be homogeneous, divide it into sub-batches that are as homogeneous as possible, then sample each sub-batch as a homogeneous batch using, as a minimum, the number of randomly selected containers indicated below.

Number of containers in batch (*N*)	Number of containers to be sampled (*n*)
1 - 3	all
> 3	$n^* = \sqrt{N} + 1$

* round *n* up to the next integer

Take one sample from each container to be sampled. The sample is taken from the upper, middle or lower section of the container, such that the samples taken are representative of different parts of the containers. In the case of large bales or bags, samples must be taken from a depth of at least 10 cm. The mass of the material taken from each container is such that the total mass of the bulk sample complies with the following values.

Mass of herbal drug in the batch (kg)	Minimum mass of samples as a percentage of the mass of the batch of herbal drug
< 50	1.00*
50 - 100	0.50
> 100 - 250	0.25
> 250 - 500	0.20
> 500 - 1000	0.18
> 1000 - 2500	0.15
> 2500 - 5000	0.10
> 5000 - 10 000	0.08
> 10 000 - 25 000	0.05

NOTE: if the mass of the batch is greater than 25 000 kg, it is divided into sub-batches, and the procedure is applied to each sub-batch as though it were a homogeneous batch.

* subject to a minimum total mass of 125 g for the bulk sample; if this minimum requirement represents more than 10.0 per cent of the mass of herbal drug in the batch, the whole batch may be used as the sample.

Prepare the bulk sample by combining and thoroughly mixing the samples taken from each of the randomly selected containers (see Table 2.8.20.-1).

TEST SAMPLE

Unless otherwise prescribed in the monograph, prepare the test sample as follows.

Reduce the size of the bulk sample by quartering (see Note below) or by any other method that produces a homogeneous sample, making sure that each retained portion remains representative of the whole, until the minimum retained quantity complies with the following conditions.

Type of herbal drug	Minimum weight of test sample
Roots, rhizomes, bark, herbs	500 g or mass of whole sample if bulk sample is less than 500 g
Leaves, flowers, seeds, fruits	250 g or mass of whole sample if bulk sample is less than 250 g
Broken or fragmented drugs (where average mass of the pieces is less than 0.5 g)	125 g

NOTE: quartering consists of placing the bulk sample, thoroughly mixed, as a level and square-shaped heap and dividing it diagonally into 4 equal parts. 2 opposite quarters are retained and carefully remixed. The process is repeated as necessary until the required minimum mass is obtained for the test sample.

Mill the test sample in a single pass through a 1 mm screen or the screen size specified in the monograph. The use of a milling machine is recommended.

Pass the milled sample through a 1 mm standard sieve or the sieve specified in the monograph. The residue retained on the sieve must not be more than 10 per cent of the total mass of the milled sample, of which not more than 2 per cent of the total mass of the milled sample may be of a particle size greater than 1.5 mm or 1.5 times the specified particle size in the monograph. If these conditions are met, the sample and residue are to be well mixed to form the test sample for analysis.

In those cases where these requirements are not met, the test sample for analysis is composed of the 2 parts measured separately. Therefore, the quantity required for each analysis is derived by weighing proportional quantities of the powder and the residue.

NOTE: for determination of microscopic characters, a portion of the milled test sample is re-milled through a 0.355 mm screen.

Table 2.8.20.-1. – *Operation of the sampling procedure in order to obtain the prescribed bulk sample*

2.9. PHARMACEUTICAL TECHNICAL PROCEDURES

01/2008:20901

2.9.1. DISINTEGRATION OF TABLETS AND CAPSULES

This test is provided to determine whether tablets or capsules disintegrate within the prescribed time when placed in a liquid medium under the experimental conditions presented below.

For the purposes of this test, disintegration does not imply complete dissolution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the discs, if used, is a soft mass having no palpably firm core.

Use apparatus A for tablets and capsules that are not greater than 18 mm long. For larger tablets or capsules use apparatus B.

TEST A - TABLETS AND CAPSULES OF NORMAL SIZE

Apparatus. The apparatus consists of a basket-rack assembly, a 1 litre, low-form beaker, 149 ± 11 mm in height and having an inside diameter of 106 ± 9 mm for the immersion fluid, a thermostatic arrangement for heating the fluid between 35 °C and 39 °C, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles per minute, through a distance of 55 ± 2 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke the wire mesh remains at least 15 mm below the surface of the fluid, and descends to not less than 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition, rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

Basket-rack assembly. The basket-rack assembly consists of 6 open-ended transparent tubes, each 77.5 ± 2.5 mm long and having an inside diameter of 21.85 ± 1.15 mm and a wall 1.9 ± 0.9 mm thick; the tubes are held in a vertical position by 2 plates, each 90 ± 2 mm in diameter and 6.75 ± 1.75 mm in thickness, with 6 holes, each 24 ± 2 mm in diameter, equidistant from the centre of the plate and equally spaced from one another. Attached to the under surface of the lower plate is a woven stainless steel wire cloth, which has a plain square weave with 2.0 ± 0.2 mm mesh apertures and with a wire diameter of 0.615 ± 0.045 mm. The parts of the apparatus are assembled and rigidly held by means of 3 bolts passing through the 2 plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device using a point on its axis.

The design of the basket-rack assembly may be varied somewhat provided the specifications for the glass tubes and the screen mesh size are maintained. The basket-rack assembly conforms to the dimensions shown in Figure 2.9.1.-1.

Discs. The use of discs is permitted only where specified or allowed. Each tube is provided with a cylindrical disc 9.5 ± 0.15 mm thick and 20.7 ± 0.15 mm in diameter. The disc is made of a suitable, transparent plastic material having a specific gravity of 1.18-1.20. 5 parallel 2 ± 0.1 mm holes extend between the ends of the cylinder. One of the holes is centered on the cylindrical axis. The other holes are centered 6 ± 0.2 mm from the axis on imaginary lines perpendicular to the axis and parallel to each other. 4 identical trapezoidal-shaped planes are cut into the wall of the cylinder, nearly perpendicular to the ends of the cylinder. The trapezoidal shape is symmetrical; its parallel sides coincide with the ends of the cylinder and are parallel to an imaginary line connecting the centres of 2 adjacent holes 6 mm from the cylindrical axis. The parallel side of the trapezoid on the bottom of the cylinder has a length of 1.6 ± 0.1 mm and its bottom edges lie at a depth of 1.6 ± 0.1 mm from the cylinder's circumference. The parallel side of the trapezoid on the top of the cylinder has a length of 9.4 ± 0.2 mm and its centre lies at a depth of 2.6 ± 0.1 mm from the cylinder's circumference. All surfaces of the disc are smooth.

If the use of discs is specified, add a disc to each tube and operate the apparatus as directed under Procedure. The discs conform to the dimensions shown in Figure 2.9.1.-1.

The use of automatic detection employing modified discs is permitted where the use of discs is specified or allowed. Such discs must comply with the requirements of density and dimension given in this chapter.

Procedure. Place 1 dosage unit in each of the 6 tubes of the basket and, if prescribed, add a disc. Operate the apparatus using the specified medium, maintained at 37 ± 2 °C, as the immersion fluid. At the end of the specified time, lift the basket from the fluid and observe the dosage units: all of the dosage units have disintegrated completely. If 1 or 2 dosage units fail to disintegrate, repeat the test on 12 additional dosage units. The requirements of the test are met if not less than 16 of the 18 dosage units tested have disintegrated.

TEST B – LARGE TABLETS AND LARGE CAPSULES

Apparatus. The main part of the apparatus (Figure 2.9.1.-2) is a rigid basket-rack assembly supporting 3 cylindrical transparent tubes 77.5 ± 2.5 mm long, 33.0 mm ± 0.5 mm in internal diameter, and with a wall thickness of 2.5 ± 0.5 mm. Each tube is provided with a cylindrical disc 31.4 ± 0.13 mm in diameter and 15.3 ± 0.15 mm thick, made of transparent plastic with a relative density of 1.18-1.20. Each disc is pierced by 7 holes, each 3.15 ± 0.1 mm in diameter, 1 in the centre and the other 6 spaced equally on a circle of radius 4.2 mm from the centre of the disc. The tubes are held vertically by 2 separate and superimposed rigid plastic plates 97 mm in diameter and 9 mm thick, with 3 holes. The holes are equidistant from the centre of the plate and equally spaced. Attached to the under side of the lower plate is a piece of woven gauze made from stainless steel wire 0.63 ± 0.03 mm in diameter and having mesh apertures of 2.0 ± 0.2 mm. The plates are held rigidly in position and 77.5 mm apart by vertical metal rods at the periphery. A metal rod is also fixed to the centre of the upper plate to enable the assembly to be attached to a mechanical device capable of raising and lowering it smoothly at a constant frequency of between 29 and 32 cycles per minute, through a distance of 55 ± 2 mm.

The assembly is suspended in the specified liquid medium in a suitable vessel, preferably a 1 litre beaker. The volume of the liquid is such that when the assembly is in the highest position the wire mesh is at least 15 mm below the surface of the liquid, and when the assembly is in the lowest position the wire mesh is at least 25 mm above the bottom of the beaker and the upper open ends of the tubes remain above

the surface of the liquid. A suitable device maintains the temperature of the liquid at 35-39 °C.

The design of the basket-rack assembly may be varied provided the specifications for the tubes and wire mesh are maintained.

Method. Test 6 tablets or capsules either by using 2 basket-rack assemblies in parallel or by repeating the procedure. In each of the 3 tubes, place 1 tablet or capsule and, if prescribed, add a disc; suspend the assembly in the beaker containing the specified liquid. Operate the apparatus for the prescribed period, withdraw the assembly and examine the state of the tablets or capsules. To pass the test, all 6 of the tablets or capsules must have disintegrated.

01/2008:20902

2.9.2. DISINTEGRATION OF SUPPOSITORIES AND PESSARIES

The disintegration test determines whether the suppositories or pessaries soften or disintegrate within the prescribed time when placed in a liquid medium in the experimental conditions described below.

Disintegration is considered to be achieved when:

a) dissolution is complete,

b) the components of the suppository or pessary have separated: melted fatty substances collect on the surface of the liquid, insoluble powders fall to the bottom and soluble components dissolve, depending on the type of preparation, the components may be distributed in one or more of these ways,

c) there is softening of the sample that may be accompanied by appreciable change of shape without complete separation of the components, the softening is such that the suppository or pessary no longer has a solid core offering resistance to pressure of a glass rod,

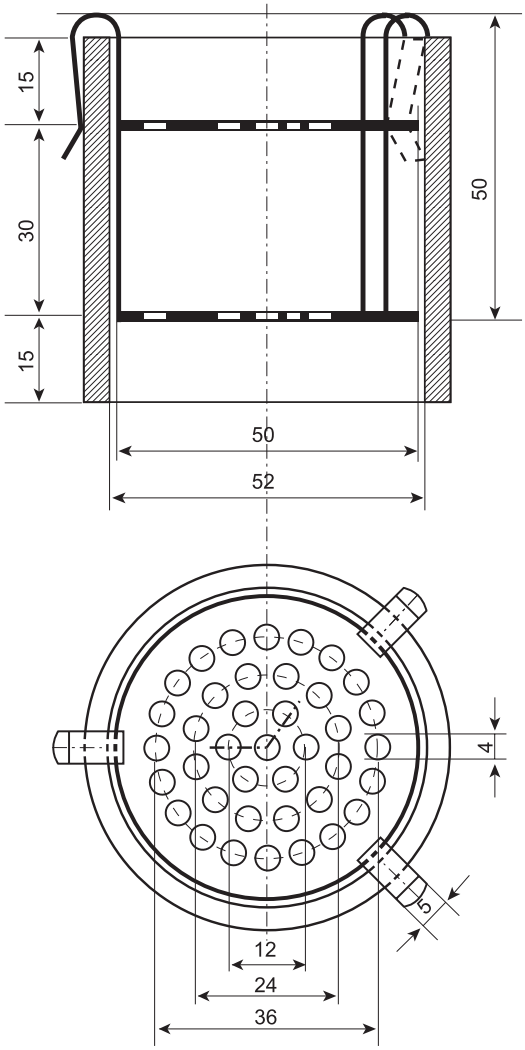
d) rupture of the gelatin shell of rectal or vaginal capsules occurs allowing release of the contents,

e) no residue remains on the perforated disc or if a residue remains, it consists only of a soft or frothy mass having no solid core offering resistance to pressure of a glass rod (vaginal tablets).

Apparatus. The apparatus (Figure 2.9.2.-1) consists of a sleeve of glass or suitable transparent plastic, of appropriate thickness, to the interior of which is attached by means of three hooks a metal device consisting of two perforated stainless metal discs each containing 39 holes 4 mm in diameter; the diameter of the discs is similar to that of the interior of the sleeve; the discs are about 30 mm apart. The test is carried out using three such apparatuses each containing a single sample. Each apparatus is placed in a

beaker with a capacity of at least 4 litres filled with water maintained at 36-37 °C, unless otherwise prescribed. The apparatuses may also be placed together in a vessel with a capacity of at least 12 litres. The beaker is fitted with a slow stirrer and a device that will hold the cylinders vertically not less than 90 mm below the surface of the water and allow them to be inverted without emerging from the water.

Method. Use three suppositories or pessaries. Place each one on the lower disc of a device, place the latter in the sleeve and secure. Invert the apparatuses every 10 min. Examine the samples after the period prescribed in the monograph. To pass the test all the samples must have disintegrated.



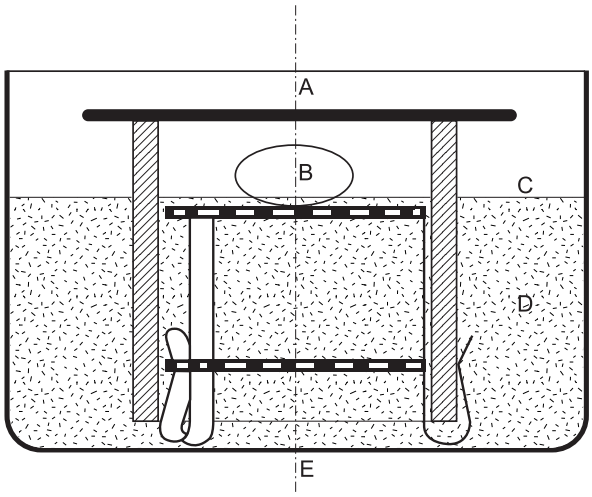


Figure 2.9.2.-1. – *Apparatus for disintegration of suppositories and pessaries*

Dimensions in millimetres

METHOD OF OPERATION FOR VAGINAL TABLETS

Use the apparatus described above, arranged so as to rest on the hooks (see Figure 2.9.2.-2). Place it in a beaker of suitable diameter containing water maintained at 36-37 °C with the level just below the upper perforated disc. Using a pipette, adjust the level with water at 36-37 °C until a uniform film covers the perforations of the disc. Use three vaginal tablets. Place each one on the upper plate of an apparatus and cover the latter with a glass plate to maintain appropriate conditions of humidity. Examine the state of the samples after the period prescribed in the monograph. To pass the test all the samples must have disintegrated.

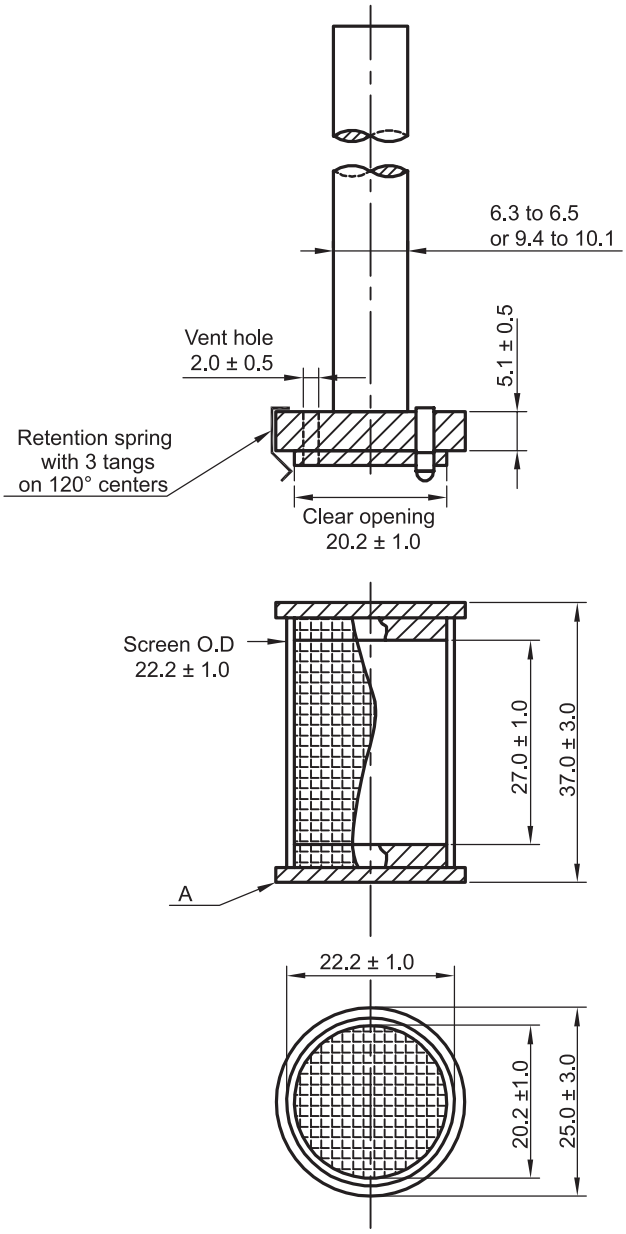
2.9.3. DISSOLUTION TEST FOR SOLID DOSAGE FORMS



This test is provided to determine compliance with the dissolution requirements for solid dosage forms administered orally. In this chapter, a dosage unit is defined as 1 tablet or 1 capsule or the amount specified.

APPARATUS

Apparatus 1 (Basket apparatus). The assembly consists of the following: a vessel, which may be covered, made of glass or other inert, transparent material(1); a motor; a drive shaft; and a cylindrical basket (stirring element). The vessel is partially immersed in a suitable water-bath of any convenient size or heated by a suitable device such as a heating jacket. The water-bath or heating device permits maintaining the temperature inside the vessel at 37 ± 0.5 °C during the test and keeping the dissolution medium in constant, smooth motion. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smoothly rotating stirring element. Apparatus that permits observation of the preparation and stirring element during the test is preferable. The vessel is cylindrical, with a hemispherical bottom and a capacity of 1 litre. Its height is 160-210 mm and its inside diameter is 98-106 mm. Its sides are flanged at the top. A fitted cover may be used to retard evaporation(2). The shaft is positioned so that its axis is not more than 2 mm at any point from the vertical axis of the vessel and rotates smoothly and without significant wobble that could affect the results. A speed-regulating device is used that allows the shaft rotation speed to be selected and maintained at a specified rate, within ± 4 per cent.

Shaft and basket components of the stirring element are fabricated of stainless steel, type 316 or equivalent, to the specifications shown in Figure 2.9.3.-1.

(1) The materials must not sorb, react, or interfere with the preparation to be tested.
(2) If a cover is used, it provides sufficient openings to allow ready insertion of the thermometer and withdrawal of samples.

1) Screen with welded seam: 0.25-0.31 mm wire diameter with wire opening of 0.36-0.44 mm. After welding the screen may be slighty altered.

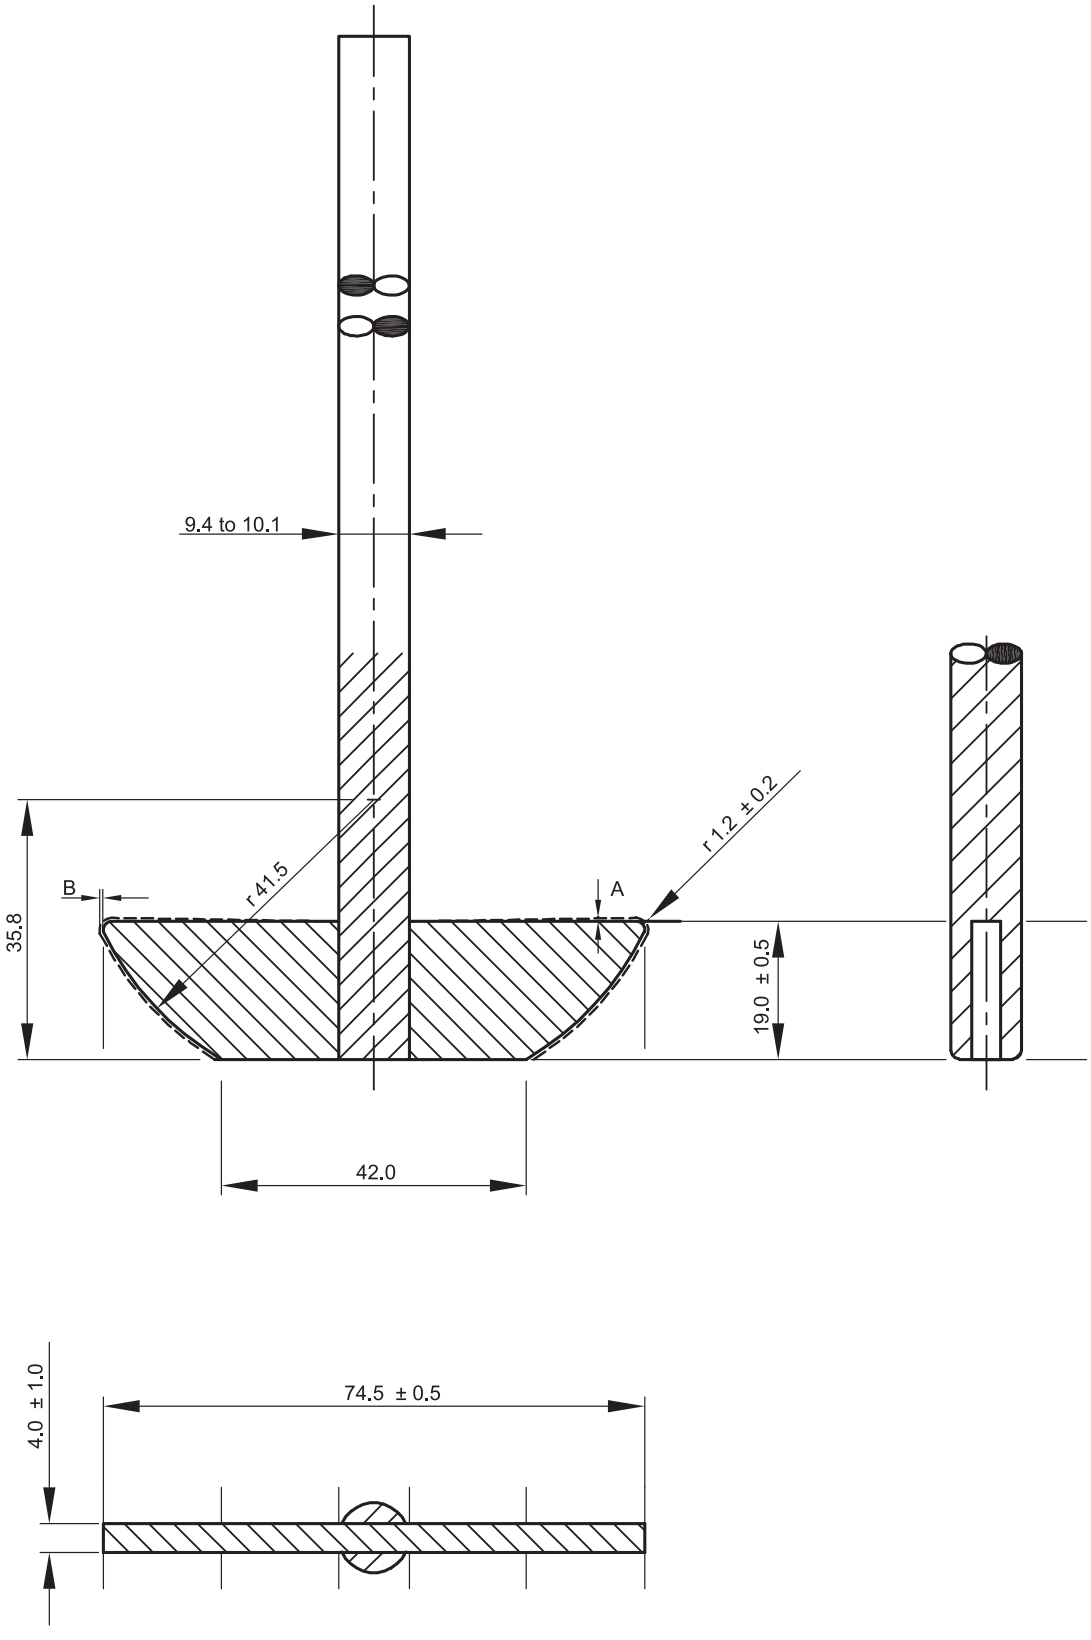
2) Maximum allowable runout at "A" is 1.0 mm when the part is rotated on center line axis with basket mounted.

Figure 2.9.3.-1. – *Apparatus 1, Basket stirring element*
Dimensions in millimetres

A basket having a gold coating of about 2.5 µm (0.0001 inch) thick may be used. The dosage unit is placed in a dry basket at the beginning of each test. The distance between the inside bottom of the vessel and the bottom of the basket is maintained at 25 ± 2 mm during the test.

Apparatus 2 (Paddle apparatus). Use the assembly from Apparatus 1, except that a paddle formed from a blade and a shaft is used as the stirring element. The shaft is positioned so that its axis is not more than 2 mm from the vertical axis of the vessel, at any point, and rotates smoothly without significant wobble that could affect the results. The vertical center line of the blade passes through the axis of the shaft so that the bottom of the blade is flush with the bottom of the shaft. The paddle conforms to the specifications shown in Figure 2.9.3.-2. The distance of 25 ± 2 mm between the bottom of the blade and the inside bottom of the vessel is maintained during the test. The metallic or suitably inert, rigid blade and shaft comprise a single entity. A suitable two-part detachable design may be used provided the assembly remains firmly engaged during the test. The paddle blade and shaft may be coated with a suitable coating so as to make them inert. The dosage unit is allowed to sink to the bottom of the vessel before rotation of the blade is started. A small, loose piece of non-reactive material, such as not more than a few turns of wire helix, may be attached to dosage units that would otherwise float. An alternative sinker device is shown in Figure 2.9.3.-3. Other validated sinker devices may be used.

Apparatus 3 (Reciprocating cylinder). The assembly consists of a set of cylindrical, flat-bottomed glass vessels; a set of glass reciprocating cylinders; inert fittings (stainless steel type 316 or other suitable material) and screens that are made of suitable nonsorbing and nonreactive material, and that are designed to fit the tops and bottoms of the reciprocating cylinders; a motor and drive assembly to reciprocate the cylinders vertically inside the vessels, and if desired, index the reciprocating cylinders horizontally to a different row of vessels. The vessels are partially immersed in a suitable water-bath of any convenient size that permits holding the temperature at 37 ± 0.5 °C during the test. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smooth, vertically reciprocating cylinder. A device is used that allows the reciprocation rate to be selected and maintained at the specified dip rate, within ± 5 per cent. An apparatus that permits observation of the preparations and reciprocating cylinders is preferable. The vessels are provided with an evaporation cap that remains in place for the duration of the test. The components conform to the dimensions shown in Figure 2.9.3.-4 unless otherwise specified.



Apparatus 4 (Flow-through cell). The assembly consists of a reservoir and a pump for the dissolution medium; a flow-through cell; a water-bath that maintains the dissolution medium at 37 ± 0.5 °C. Use the specified cell size.

The pump forces the dissolution medium upwards through the flow-through cell. The pump has a delivery range between 240 ml/h and 960 ml/h, with standard flow rates of 4 ml/min, 8 ml/min, and 16 ml/min. It must deliver a constant flow (± 5 per cent of the nominal flow rate); the flow profile is sinusoidal with a pulsation of 120 ± 10 pulses/min. Non-pulsated flow may also be used.

The flow-through cell (see Figures 2.9.3.-5 and 2.9.3.-6) of transparent and inert material is mounted vertically, with a filter system that prevents escape of undissolved particles from the top of the cell; standard cell diameters are 12 mm and 22.6 mm; the bottom cone is usually filled with small glass beads of about 1 mm diameter, with 1 bead of about 5 mm positioned at the apex to protect the fluid entry tube; a tablet holder (see Figures 2.9.3.-5 and 2.9.3.-6) is available for positioning of special dosage forms. The cell is immersed in a water-bath, and the temperature is maintained at 37 ± 0.5 °C.

The apparatus uses a clamp mechanism and 2 O-rings for the fixation of the cell assembly. The pump is separated from the dissolution unit in order to shield the latter against any vibrations originating from the pump. The position of the pump must not be on a level higher than the reservoir flasks. Tube connections are as short as possible. Use suitably inert tubing, such as polytetrafluoroethylene, with a 1.6 mm inner diameter and inert flanged-end connections.

Apparatus suitability. The determination of suitability of the apparatus to perform dissolution testing must include conformance to the dimensions and tolerances of the apparatus as given above. In addition, critical test parameters that have to be monitored periodically during use include

A and B dimensions do not vary more than 0.5 mm when part is rotated on center line axis.
Tolerances are ± 1.0 mm unless otherwise stated.

Figure 2.9.3.-2. – *Apparatus 2, Paddle stirring element*
Dimensions in millimetres

volume and temperature of the dissolution medium, rotation speed (Apparatus 1 and 2, dip rate (Apparatus 3), and flow rate of medium (Apparatus 4).

Determine the acceptable performance of the dissolution test assembly periodically.

PROCEDURE

APPARATUS 1 AND 2

Conventional-release solid dosage forms

Procedure. Place the stated volume of the dissolution medium (± 1 per cent) in the vessel of the specified apparatus.

Assemble the apparatus, equilibrate the dissolution medium to 37 ± 0.5 °C, and remove the thermometer. The test may also be carried out with the thermometer in place, provided it is shown that results equivalent to those obtained without the thermometer are obtained.

Place 1 dosage unit in the apparatus, taking care to exclude air bubbles from the surface of the dosage unit. Operate the apparatus at the specified rate. Within the time interval specified, or at each of the times stated, withdraw a specimen from a zone midway between the surface of the dissolution medium and the top of the rotating basket or blade, not less than 1 cm from the vessel wall. Where multiple sampling times are specified, replace the aliquots withdrawn for analysis with equal volumes of fresh dissolution medium at 37 °C or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered for the duration of the test and verify the temperature of the medium at suitable times. Perform the analysis using a suitable assay method(3). Repeat the test with additional dosage units.

If automated equipment is used for sampling or the apparatus is otherwise modified, verification that the modified apparatus will produce results equivalent to those obtained with the apparatus described in this chapter, is necessary.

Dissolution medium. A suitable dissolution medium is used. The volume specified refers to measurements made between 20 °C and 25 °C. If the dissolution medium is a buffered solution, adjust the solution so that its pH is within 0.05 units of the specified pH. Dissolved gases can cause bubbles to form, which may change the results of the test. In such cases, dissolved gases must be removed prior to testing(4).

Time. Where a single time specification is given, the test may be concluded in a shorter period if the requirement for minimum amount dissolved is met. Samples are to be withdrawn only at the stated times, within a tolerance of ± 2 per cent.

Prolonged-release solid dosage forms

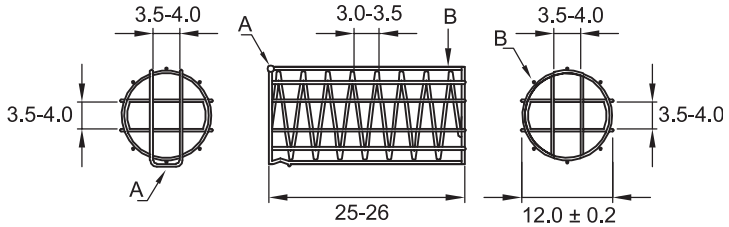
Procedure. Proceed as described for conventional-release dosage forms.

Dissolution medium. Proceed as described for conventional-release dosage forms.

Time. The test-time points, generally 3, are expressed in hours.

Delayed-release solid dosage forms

Procedure. Use Method A or Method B.



Method A

– *Acid stage.* Place 750 ml of *0.1 M hydrochloric acid* in the vessel, and assemble the apparatus. Allow the medium to equilibrate to a temperature of 37 ± 0.5 °C. Place 1 dosage unit in the apparatus, cover the vessel and operate the apparatus at the specified rate. After 2 h of operation in *0.1 M hydrochloric acid*, withdraw an aliquot of the fluid and proceed immediately as directed under Buffer stage. Perform an analysis of the aliquot using a suitable assay method.
– *Buffer stage.* Complete the operations of adding the buffer and adjusting the pH within 5 min. With the apparatus operating at the rate specified, add to the fluid in the vessel 250 ml of 0.20 M solution of *trisodium phosphate dodecahydrate R* that has been equilibrated to 37 ± 0.5 °C. Adjust, if necessary, with *2 M hydrochloric acid R* or *2 M sodium hydroxide R* to a pH of 6.8 ± 0.05. Continue to operate the apparatus for 45 min, or for the specified time. At the end of the time period, withdraw an aliquot of the fluid and perform the analysis using a suitable assay method.

Method B

– *Acid Stage.* Place 1000 ml of *0.1 M hydrochloric acid* in the vessel and assemble the apparatus. Allow the medium to equilibrate to a temperature of 37 ± 0.5 °C. Place 1 dosage unit in the apparatus, cover the vessel, and operate the apparatus at the specified rate. After 2 h of operation in *0.1 M hydrochloric acid*, withdraw an aliquot of the fluid, and proceed immediately as directed under Buffer stage. Perform an analysis of the aliquot using a suitable assay method.
– *Buffer stage.* For this stage of the procedure use buffer that has previously been equilibrated to a temperature of 37 ± 0.5 °C. Drain the acid from the vessel and add 1000 ml of pH 6.8 phosphate buffer, prepared by mixing 3 volumes of *0.1 M hydrochloric acid* with 1 volume of 0.20 M solution of *trisodium phosphate dodecahydrate R* and adjusting, if necessary, with *2 M hydrochloric acid R* or *2 M sodium hydroxide R* to a pH of 6.8 ± 0.05. This may also be accomplished by removing from the apparatus the vessel containing the acid and replacing it with another vessel, containing the buffer and transferring the dosage unit to the vessel containing the buffer. Continue to operate the apparatus for 45 min, or for the specified time. At the end of the time period, withdraw an aliquot of the fluid and perform the analysis using a suitable assay method.

Time. All test times stated are to be observed within a tolerance of ± 2 per cent, unless otherwise specified.

A: acid-resistant wire clasp

B: acid-resistant wire support

Figure 2.9.3.-3. – *Alternative sinker*
Dimensions in millimetres

(3) Test specimens are filtered immediately upon sampling unless filtration is demonstrated to be unnecessary. Use an inert filter that does not cause adsorption of the active substance or contain extractable substances that would interfere with the analysis.
(4) A method of deaeration is as follows: heat the medium, while stirring gently, to about 41 °C, immediately filter under vacuum using a filter having a porosity of 0.45 µm or less, with vigorous stirring, and continue stirring under vacuum for about 5 min. Other validated deaeration techniques for removal of dissolved gases may be used.

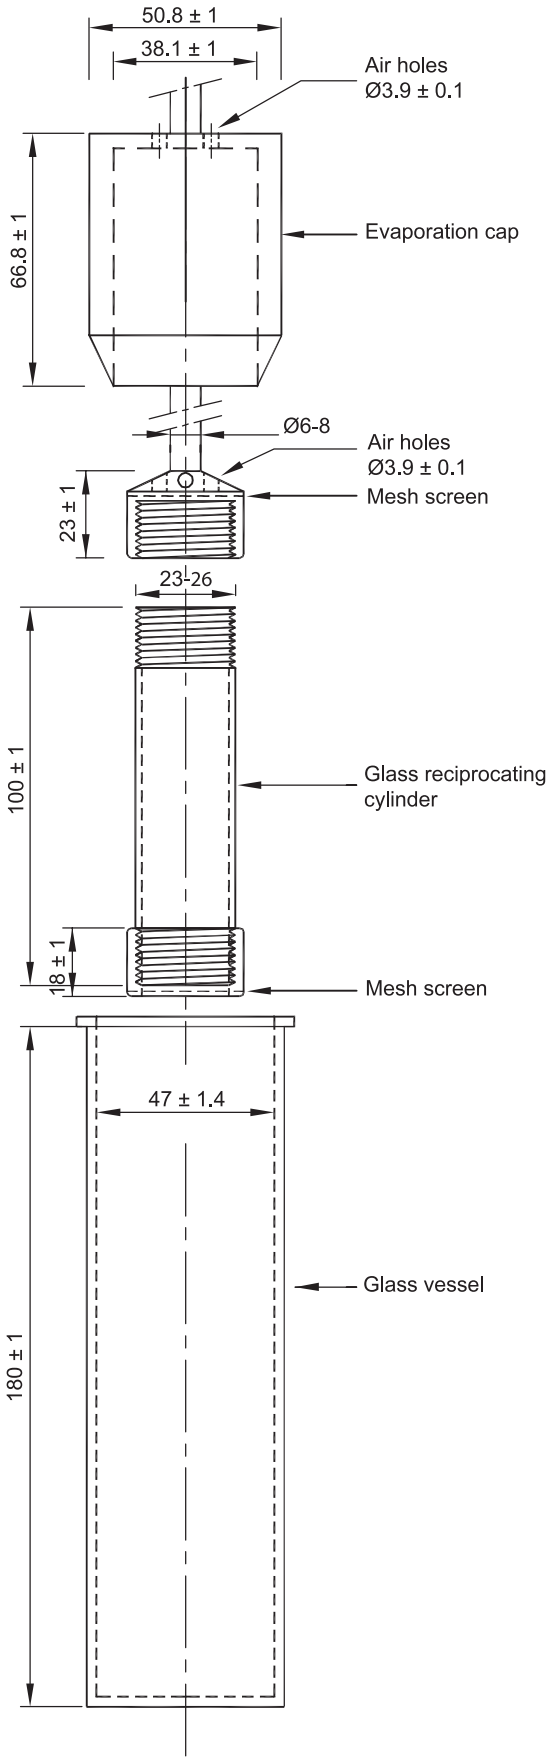


Figure 2.9.3.-4. – *Apparatus 3, glass vessel and reciprocating cylinder*

Dimensions in millimetres unless otherwise specified

APPARATUS 3

Conventional-release solid dosage forms

Procedure. Place the stated volume of the dissolution medium (± 1 per cent) in each vessel of the apparatus. Assemble the apparatus, equilibrate the dissolution medium to 37 ± 0.5 °C, and remove the thermometer. Place 1 dosage unit in each of the reciprocating cylinders, taking care to exclude air bubbles from the surface of each dosage unit, and immediately operate the apparatus as specified. During the upward and downward stroke, the reciprocating cylinder moves through a total distance of 9.9-10.1 cm. Within the time interval specified, or at each of the times stated, raise the reciprocating cylinders and withdraw a portion of the medium from a zone midway between the surface of the dissolution medium and the bottom of each vessel. Perform the analysis as directed. If necessary, repeat the test with additional dosage units.

Replace the aliquot withdrawn for analysis with equal volumes of fresh dissolution medium at 37 °C or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered with the evaporation cap for the duration of the test and verify the temperature of the medium at suitable times.

Dissolution medium. Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

Time. Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

Prolonged-release dosage forms

Procedure. Proceed as described for conventional-release dosage forms under Apparatus 3.

Dissolution medium. Proceed as described for prolonged-release dosage forms under Apparatus 1 and 2.

Time. Proceed as described for prolonged-release dosage forms under Apparatus 1 and 2.

Delayed-release dosage forms

Procedure. Proceed as described for delayed-release dosage forms, Method B, under Apparatus 1 and 2, using one row of vessels for the acid stage media and the following row of vessels for the buffer stage media, and using the volume of medium specified (usually 300 ml).

Time. Proceed as directed for delayed-release dosage forms under Apparatus 1 and 2.

APPARATUS 4

Conventional-release dosage forms

Procedure. Place the glass beads into the cell specified. Place 1 dosage unit on top of the beads or, if specified, on a wire carrier. Assemble the filter head and fix the parts together by means of a suitable clamping device. Introduce by the pump the dissolution medium warmed to 37 ± 0.5 °C through the bottom of the cell to obtain the flow rate specified and measured with an accuracy of 5 per cent. Collect the eluate by fractions at each of the times stated. Perform the analysis as directed. Repeat the test with additional dosage units.

Dissolution medium. Proceed as described for conventional-release dosage forms under Apparatus 1 and 2

Time. Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

Prolonged-release dosage forms

Procedure. Proceed as described for conventional-release dosage forms under Apparatus 4.

Dissolution medium. Proceed as described for conventional-release dosage forms under Apparatus 4.

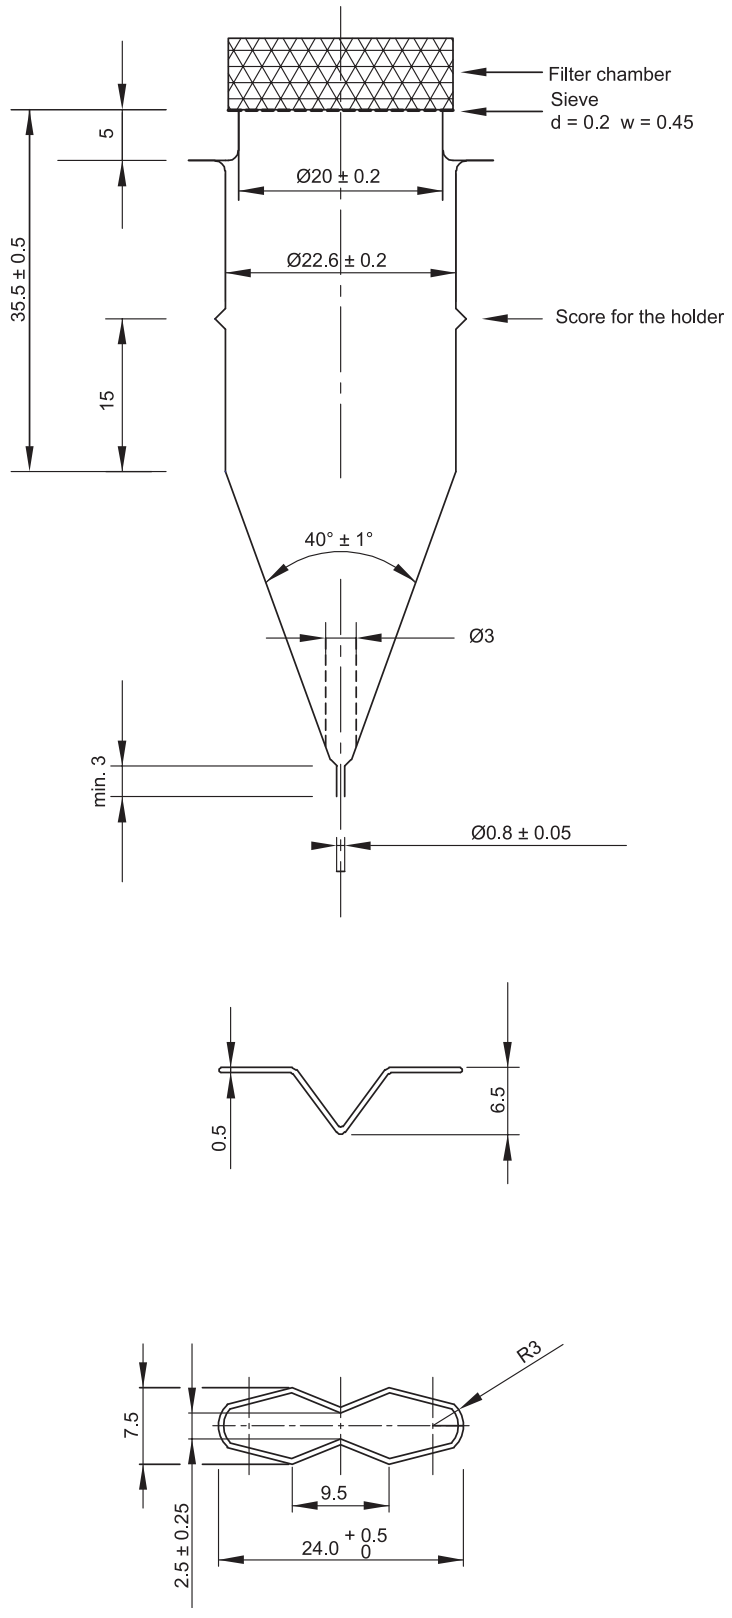

Figure 2.9.3.-5. – *Apparatus 4, large cell for tablets and capsules (top), tablet holder for the large cell (bottom) Dimensions in millimetres unless otherwise specified*

Time. Proceed as described for conventional-release dosage forms under Apparatus 4.

Delayed-release dosage forms

Procedure. Proceed as described for delayed-release dosage forms under Apparatus 1 and 2, using the specified media.

Time. Proceed as described for delayed-release dosage forms under Apparatus 1 and 2.

INTERPRETATION

Conventional-release solid dosage forms

Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the dosage units tested conform to Table 2.9.3.-1. Continue testing through the 3 levels unless the results conform at either S_1 or S_2. The quantity Q, is the specified amount of dissolved active substance, expressed as a percentage of the

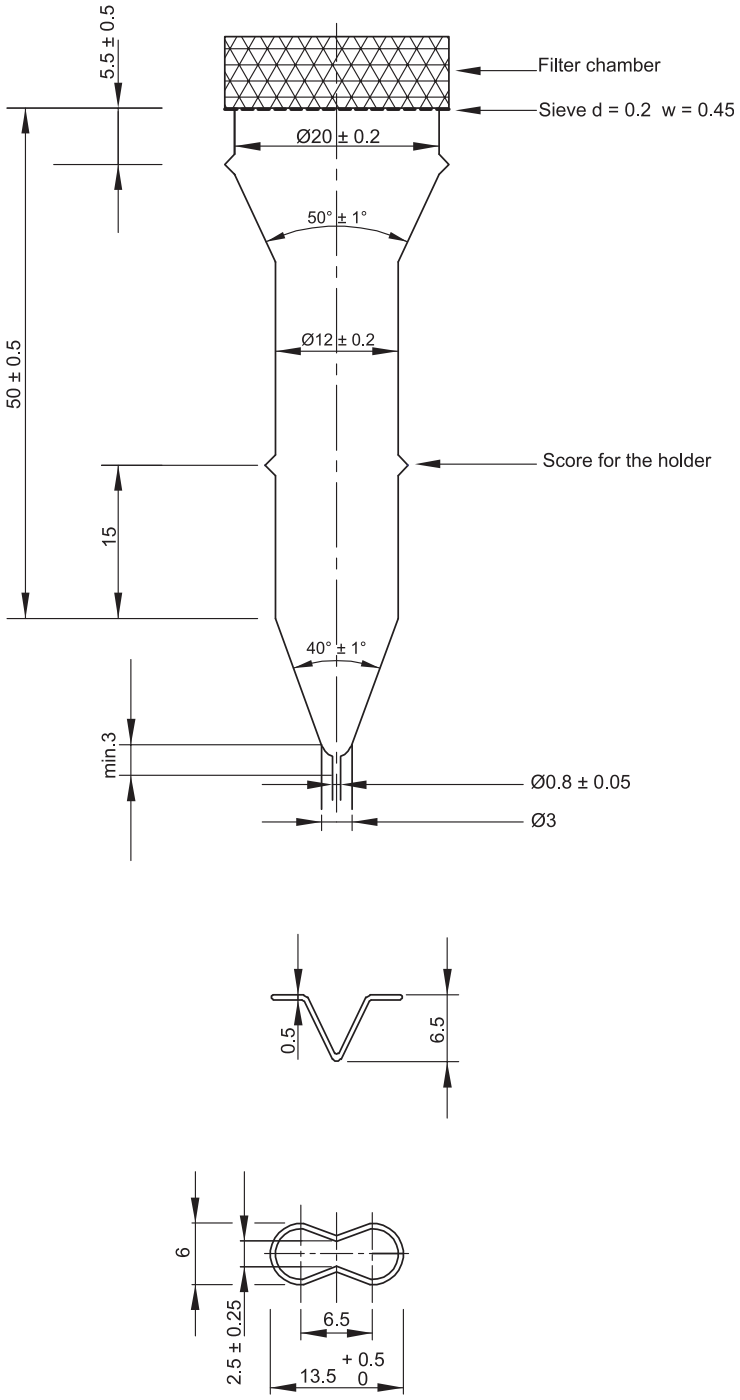

Figure 2.9.3.-6. – *Apparatus 4, small cell for tablets and capsules (top), tablet holder for the small cell (bottom)*
Dimensions in millimetres unless otherwise specified

labelled content; the 5 per cent, 15 per cent, and 25 per cent values in the Table are percentages of the labelled content so that these values and Q are in the same terms.

Table 2.9.3.-1

Level	Number tested	Acceptance criteria
S_1	6	Each unit is not less than Q + 5 per cent.
S_2	6	Average of 12 units (S_1 + S_2) is equal to or greater than Q, and no unit is less than Q – 15 per cent.
S_3	12	Average of 24 units (S_1 + S_2 + S_3) is equal to or greater than Q, not more than 2 units are less than Q – 15 per cent, and no is less than Q – 25 per cent.

Prolonged-release dosage forms

Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the dosage units tested conform to Table 2.9.3.-2. Continue testing through the 3 levels unless the results conform at either L_1 or L_2. Limits on the amounts of active substance dissolved are expressed in terms of the percentage of labelled content. The limits embrace each value of Q_i, the amount dissolved at each specified fractional dosing interval. Where more than one range is specified, the acceptance criteria apply individually to each range.

Table 2.9.3.-2

Level	Number tested	Acceptance criteria
L_1	6	No individual value lies outside each of the stated ranges and no individual value is less than the stated amount at the final test time.
L_2	6	The average value of the 12 units ($L_1 + L_2$) lies within each of the stated ranges and is not less than the stated amount at the final test time; none is more than 10 per cent of labelled content outside each of the stated ranges; and none is more than 10 per cent of labelled content below the stated amount at the final test time.
L_3	12	The average value of the 24 units ($L_1 + L_2 + L_3$) lies within each of the stated ranges, and is not less than the stated amount at the final test time; not more than 2 of the 24 units are more than 10 per cent of labelled content outside each of the stated ranges; not more than 2 of the 24 units are more than 10 per cent of labelled content below the stated amount at the final test time; and none of the units is more than 20 per cent of labelled content outside each of the stated ranges or more than 20 per cent of labelled content below the stated amount at the final test time.

Delayed-release dosage forms

Acid stage. Unless otherwise specified, the requirements of this portion of the test are met if the quantities, based on the percentage of the labelled content of active substance dissolved from the units tested conform to Table 2.9.3.-3. Continue testing through the 3 levels unless the results of both acid and buffer stages conform at an earlier level.

Table 2.9.3.-3

Level	Number tested	Acceptance criteria
A_1	6	No individual value exceeds 10 per cent dissolved.
A_2	6	The average value of the 12 units ($A_1 + A_2$) is not more than 10 per cent dissolved, and no individual unit is greater than 25 per cent dissolved.
A_3	12	The average value of the 24 units ($A_1 + A_2 + A_3$) is not more than 10 per cent dissolved, and no individual unit is greater than 25 per cent dissolved.

Buffer stage. Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the units tested conform to Table 2.9.3.-4. Continue testing through the 3 levels unless the results of both stages conform at an earlier level. The value of Q in Table 2.9.3.-4 is 75 per cent dissolved unless otherwise specified. The quantity, Q, is the specified total amount of active substance dissolved in both the acid and buffer stages, expressed as a percentage of the labelled content. The 5 per cent, 15 per cent and 25 per cent values in the Table are percentages of the labelled content so that these values and Q are in the same terms.

Table 2.9.3.-4

Level	Number tested	Acceptance criteria
B_1	6	No unit is less than $Q + 5$ per cent.
B_2	6	The average value of the 12 units ($B_1 + B_2$) is equal to or greater than Q, and no unit is less than $Q - 15$ per cent.
B_3	12	The average value of the 24 units ($B_1 + B_2 + B_3$) is equal to or greater than Q, not more than 2 units are less than $Q - 15$ per cent, and no unit is less than $Q - 25$ per cent.

The following section is published for information

Guidance on dissolution testing

In the determination of the dissolution rate of the active substance(s) of a solid dosage form, the following are to be specified:

- the apparatus to be used, and in cases where the flow-through apparatus is specified, which flow-through cell is to be used;
- the composition, the volume and the temperature of the dissolution medium;
- the rotation speed or the flow rate of the dissolution medium;
- the time, the method and the amount for sampling of the test solution or the conditions for continuous monitoring;
- the method of analysis;
- the acceptance criteria.

The choice of apparatus to be used depends on the physico-chemical characteristics of the dosage form. When a large quantity of dissolution medium is required to ensure sink conditions, or when a change of pH is necessary, the flow-through apparatus may be preferred.

EXPERIMENTAL TESTING CONDITIONS

The use of the basket and the paddle apparatus and the reciprocating cylinder apparatus is generally based on the principle of operating under "sink conditions", i.e. in such a manner that the material already in solution does not exert a significant modifying effect on the rate of dissolution of the remainder. "Sink conditions" normally occur in a volume of dissolution medium that is at least 3 to 10 times the saturation volume.

In general, an aqueous medium is used. The composition of the medium is chosen on the basis of the physico-chemical characteristics of the active substance(s) and excipient(s) within the range of conditions to which the dosage form is likely to be exposed after its administration. This applies in particular to the pH and the ionic strength of the dissolution medium.

The pH of the dissolution medium is usually set between pH 1 and 8. In justified cases, a higher pH may be needed. For the lower pH values in the acidic range, *0.1 M hydrochloric acid* is normally used. Recommended dissolution media are described hereafter.

Water is recommended as a dissolution medium only when it is proven that the pH variations do not have an influence on the dissolution characteristics.

In specific cases, dissolution media may contain enzymes, surfactants, further inorganic substances and organic substances. For the testing of preparations containing poorly aqueous-soluble active substances, modification of the medium may be necessary. In such circumstances, a low concentration of surfactant is recommended; it is recommended to avoid the use of organic solvents.

Gases dissolved in the dissolution medium can affect the results of the dissolution test. This is true, in particular, for the flow-through apparatus where de-aeration of the medium is necessary to avoid the formation of gas bubbles in the flow-through cell. A suitable method of de-aeration is as follows: heat the medium while stirring gently to about 41 °C, immediately filter under vacuum using a filter with a porosity of 0.45 µm or less, with vigorous stirring, and continue stirring under vacuum for about 5 min. Other de-aeration techniques for removal of dissolved gases may be used.

Using the paddle or basket apparatus, the volume of dissolution medium is normally 500-1000 ml. A stirring speed of between 50 r/min and 100 r/min is normally chosen; it must not exceed 150 r/min.

For the flow-through apparatus, the liquid flow rate is normally set between 4 ml/min and 50 ml/min.

RECOMMENDED DISSOLUTION MEDIA

The following dissolution media may be used.

Table 2.9.3.-5. – *Examples of dissolution media*

pH	Dissolution media
pH 1.0	HCl
pH 1.2	NaCl, HCl
pH 1.5	NaCl, HCl
pH 4.5	Phosphate or acetate buffer
pH 5.5 and 5.8	Phosphate or acetate buffer
pH 6.8	Phosphate buffer
pH 7.2 and 7.5	Phosphate buffer

The composition and preparation of these various media are indicated below.

Hydrochloric acid media

– *0.2 M hydrochloric acid,*

– *0.2 M sodium chloride.* Dissolve 11.69 g of *sodium chloride R* in *water R* and dilute to 1000.0 ml with the same solvent.

For preparing media with the following pH, place 250.0 ml of 0.2 M sodium chloride in a 1000 ml volumetric flask, add the specified volume of *0.2 M hydrochloric acid,* then dilute to 1000.0 ml with *water R* (see Table 2.9.3.-6.).

The hydrochloric acid media may also be prepared by replacing sodium chloride by potassium chloride.

Acetate buffer solutions

– *2 M acetic acid.* Dilute 120.0 g of *glacial acetic acid R* to 1000.0 ml with *water R.*

– *Acetate buffer solution pH 4.5.* Dissolve 2.99 g of *sodium acetate R* in *water R.* Add 14.0 ml of 2 M acetic acid and dilute to 1000.0 ml with *water R.*

– *Acetate buffer solution pH 5.5.* Dissolve 5.98 g of *sodium acetate R* in *water R.* Add 3.0 ml of 2 M acetic acid and dilute to 1000.0 ml with *water R.*

– *Acetate buffer solution pH 5.8.* Dissolve 6.23 g of *sodium acetate R* in *water R.* Add 2.1 ml of 2 M acetic acid and dilute to 1000.0 ml with *water R.*

Phosphate buffer solutions

For preparing buffers with the pH values indicated in Table 2.9.3.-7, place 250.0 ml of *0.2 M potassium dihydrogen phosphate R* in a 1000 ml volumetric flask, add the specified volume of *0.2 M sodium hydroxide,* then dilute to 1000.0 ml with *water R.*

Other phosphate buffer solutions

– *Phosphate buffer solution pH 4.5.* Dissolve 13.61 g of *potassium dihydrogen phosphate R* in 750 ml of *water R.* Adjust the pH (*2.2.3*) if necessary with *0.1 M sodium hydroxide* or with *0.1 M hydrochloric acid.* Dilute to 1000.0 ml with *water R.*

– *Phosphate buffer solution pH 5.5 R.*

– *Phosphate buffer solution pH 6.8 R1.*

– *Buffer solution pH 7.2 R.*

– *0.33 M phosphate buffer solution pH 7.5 R.*

Table 2.9.3.-7. – *Phosphate buffer solutions*

pH	5.8	6.0	6.2	6.4	6.6	6.8
NaOH (ml)	18.0	28.0	40.5	58.0	82.0	112.0
pH	7.0	7.2	7.4	7.6	7.8	8.0
NaOH (ml)	145.5	173.5	195.5	212.0	222.5	230.5

Simulated intestinal fluid pH 6.8

Mix 250.0 ml of a solution containing 6.8 g of *potassium dihydrogen phosphate R,* 77.0 ml of *0.2 M sodium hydroxide* and 500 ml of *water R.* Add 10.0 g of *pancreas powder R,* mix and adjust the pH (*2.2.3*), if necessary. Dilute to 1000.0 ml with *water R.*

Artificial gastric juice

Dissolve 2.0 g of *sodium chloride R* and 3.2 g of *pepsin powder R* in *water R.* Add 80 ml of *1 M hydrochloric acid* and dilute to 1000.0 ml with *water R.* If required, pepsin powder may be omitted.

Increasing pH

For a test involving increasing pH, one of the following sequences may be used:

Time (h)	0 - 1	1 - 2	2 - 3	3 - 4	4 - 5	5 - 6	6 - 7	7
pH	1.0							
pH	1.2	6.8						
pH	1.2	2.5	4.5		7.0		7.5	
pH	1.5	4.5			7.2			

To achieve this pH variation, it is possible either:

– to substitute one buffer solution for another (whole substitution);

– to remove only half of the medium each time (half change method) and replace it with a buffer solution of higher pH: the initial pH is 1.2 and the second solution is phosphate buffer solution pH 7.5;

– to an initial solution at pH 1.5, add a dose of a powder mixture containing *tris(hydroxymethyl)aminomethane R* and *anhydrous sodium acetate R* to obtain pH 4.5 and a second dose to obtain pH 7.2, as described below:

  – *hydrochloric acid pH 1.5.* Dissolve 2 g of *sodium chloride R* in *water R,* add 31.6 ml of *hydrochloric acid R* and dilute to 1000.0 ml with *water R*;

  – *buffer solution pH 4.5.* Mix 2.28 g of *tris(hydroxymethyl)aminomethane R* with 1.77 g of *anhydrous sodium acetate R.* Dissolve this mixture in the hydrochloric acid solution pH 1.5 described above;

  – *buffer solution pH 7.2.* Mix 2.28 g of *tris(hydroxymethyl)aminomethane R* with 1.77 g of *anhydrous sodium acetate R.* Dissolve this mixture in the buffer solution pH 4.5 described above.

The flow-through cell may be used for the continuous change of pH.

Table 2.9.3.-6. – *Hydrochloric acid media*

pH	1.2	1.3	1.4	1.5	1.6	1.7	1.8	1.9	2.0	2.1	2.2
HCl (ml)	425.0	336.0	266.0	207.0	162.0	130.0	102.0	81.0	65.0	51.0	39.0

QUALIFICATION AND VALIDATION

Due to the nature of the test method, quality by design is an important qualification aspect for *in vitro* dissolution test equipment. Any irregularities such as vibration or undesired agitation by mechanical imperfections are to be avoided.

Qualification of the dissolution test equipment has to consider the dimensions and tolerances of the apparatus. Critical test parameters, such as temperature and volume of dissolution medium, rotation speed or liquid flow rate, sampling probes and procedures have to be monitored periodically during the periods of use.

The performance of the dissolution test equipment may be monitored by testing a reference product which is sensitive to hydrodynamic conditions. Such tests may be performed periodically or continuously for comparative reasons with other laboratories.

During testing, critical inspection and observation are required. This approach is especially important to explain any out-lying results.

Validation of automated systems, whether concerning the sampling and analytical part or the dissolution media preparation and test performance, has to consider accuracy, precision, and the avoidance of contamination by any dilutions, transfers, cleaning and sample or solvent preparation procedures.

DISSOLUTION SPECIFICATIONS FOR ORAL DOSAGE FORMS

The dissolution specification is expressed as the quantity *Q* of the active substance as a percentage of the content stated on the product label, which is dissolved in a specified time frame.

Conventional-release dosage forms

Unless otherwise specified, the value of *Q* is 75 per cent. In most cases, when tested under reasonable and justified test conditions at least 75 per cent of the active substance is released within 45 min. Typically, one limit is specified to ensure that most of the active substance is dissolved within the pre-set time period.

In cases where a longer release time than that recommended above is justified, limits at 2 time intervals may be specified.

Prolonged-release dosage forms

A manufacturer's dissolution specification for prolonged-release dosage forms is normally expected to consist of 3 or more points. The first specification point is intended to prevent unintended rapid release of the active substance ('dose dumping'). It is therefore set after a testing period corresponding to a dissolved amount of typically 20 per cent to 30 per cent. The second specification point defines the dissolution pattern and so is set at around 50 per cent release. The final specification point is intended to ensure almost complete release which is generally understood as more than 80 per cent release.

Delayed-release dosage forms

A delayed-release dosage form may release the active substance(s) fractionally or totally according to the formulation design when tested in different dissolution media, e.g. in increasing pH conditions. Dissolution specifications have, therefore, to be decided from case to case.

Gastro-resistant dosage forms require at least 2 specification points in a sequential test and 2 different specifications in a parallel test. In a sequential test, the first specification point is set after 1 h or 2 h in acidic medium and the second one at a pre-set time period of testing in an adequate buffer solution (preferably pH 6.8). Unless otherwise specified, the value of *Q* is 75 per cent.

01/2008:20904

2.9.4. DISSOLUTION TEST FOR TRANSDERMAL PATCHES

This test is used to determine the dissolution rate of the active ingredients of transdermal patches.

1. DISK ASSEMBLY METHOD

Equipment. Use the paddle and vessel assembly from the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*) with the addition of a stainless steel disk assembly (SSDA) in the form of a net with an aperture of 125 µm (see Figure 2.9.4.-1).

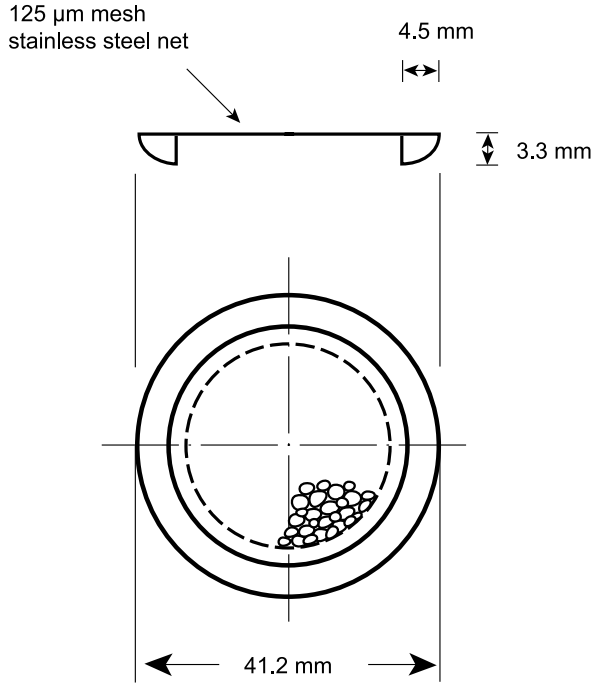

Figure 2.9.4.-1. – *Disk assembly*

The SSDA holds the system at the bottom of the vessel and is designed to minimise any dead volume between the SSDA and the bottom of the vessel. The SSDA holds the patch flat, with the release surface uppermost and parallel to the bottom of the paddle blade. A distance of 25 ± 2 mm between the bottom of the paddle blade and the surface of the SSDA is maintained during the test (see Figure 2.9.4.-2). The temperature is maintained at 32 ± 0.5 °C. The vessel may be covered during the test to minimise evaporation.

Procedure. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Apply the patch to the SSDA, ensuring that the release surface of the patch is as flat as possible. The patch may be attached to the SSDA by a prescribed adhesive or by a strip of a double-sided adhesive tape. The adhesive or tape are previously tested for the absence of interference with the assay and of adsorption of the active ingredient(s). Press the patch, release surface facing up, onto the side of the SSDA made adhesive. The applied patch must not overlap the borders of the SSDA. For this purpose and provided that the preparation is homogeneous and uniformly spread on the outer covering, an appropriate and exactly measured piece of the patch

may be cut and used for testing the dissolution rate. This procedure may also be necessary to achieve appropriate sink conditions. This procedure must not be applied to membrane-type patches. Place the patch mounted on the SSDA flat at the bottom of the vessel with the release surface facing upwards. Immediately rotate the paddle at 100 r/min, for example. At predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the blade, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume losses, as necessary. Repeat the test with additional patches.

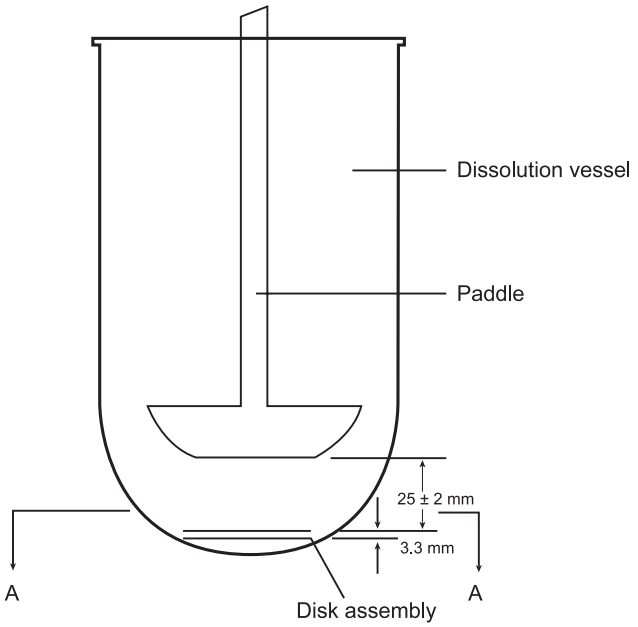

Figure 2.9.4.-2. – *Paddle and disk*

2. CELL METHOD

Equipment. Use the paddle and vessel assembly from the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*) with the addition of the extraction cell (*cell*).

The *cell* is made of chemically inert materials and consists of a *support*, a *cover* and, if necessary, a *membrane* placed on the patch to isolate it from the medium that may modify or adversely affect the physico-chemical properties of the patch (see Figure 2.9.4.-3).

Support. The central part of the support forms a cavity intended to hold the patch. The cavity has a depth of 2.6 mm and a diameter that is appropriate to the size of the patch to be examined. The following diameters can be used: 27 mm, 38 mm, 45 mm, 52 mm, corresponding to volumes of 1.48 ml, 2.94 ml, 4.13 ml, 5.52 ml, respectively.

Cover. The cover has a central opening with a diameter selected according to the size of the patch to be examined. The patch can thus be precisely centred, and its releasing surface limited. The following diameters may be used: 20 mm, 32 mm, 40 mm, 50 mm corresponding to areas of 3.14 cm^2, 8.03 cm^2, 12.56 cm^2, 19.63 cm^2, respectively. The cover is held in place by nuts screwed onto bolts projecting from the support. The cover is sealed to the support by a rubber ring set on the reservoir.

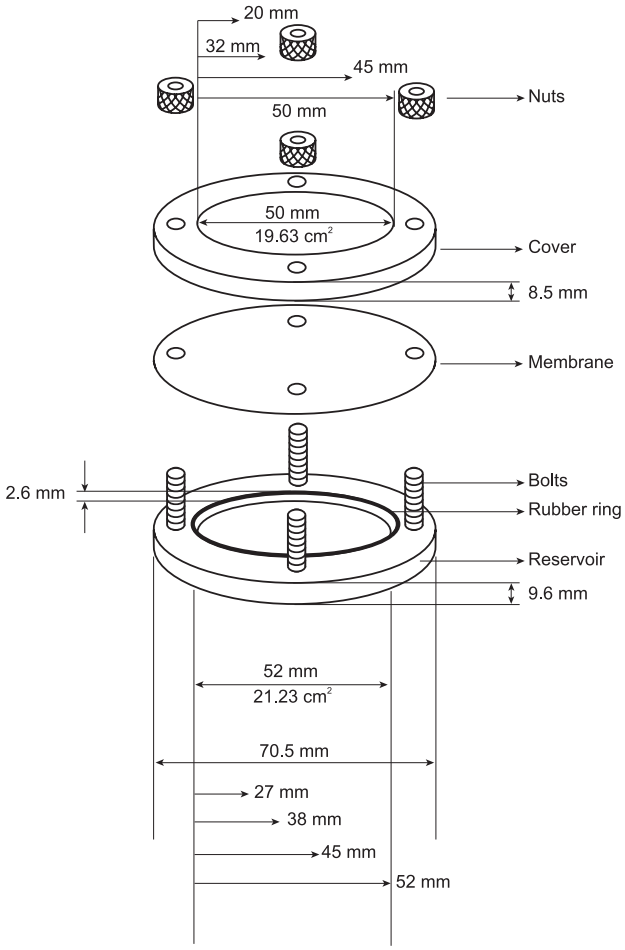

Figure 2.9.4.-3. – *Extraction cell*

Extraction cell. The *cell* holds the patch flat, with the release surface uppermost and parallel to the bottom of the paddle blade. A distance of 25 ± 2 mm is maintained between the paddle blade and the surface of the patch (see Figure 2.9.4.-4). The temperature is maintained at 32 ± 0.5 °C. The vessel may be covered during the test to minimise evaporation.

Procedure. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Precisely centre the patch in the *cell* with the releasing surface uppermost. Close the *cell*, if necessary applying a hydrophobic substance (for example, petrolatum) to the flat surfaces to ensure the seal, and ensure that the patch stays in place. Introduce the cell flat into the bottom of the vessel with the cover facing upwards. Immediately rotate the paddle, at 100 r/min for example. At predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the paddle blade, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume losses, as necessary. Repeat the test with additional patches.

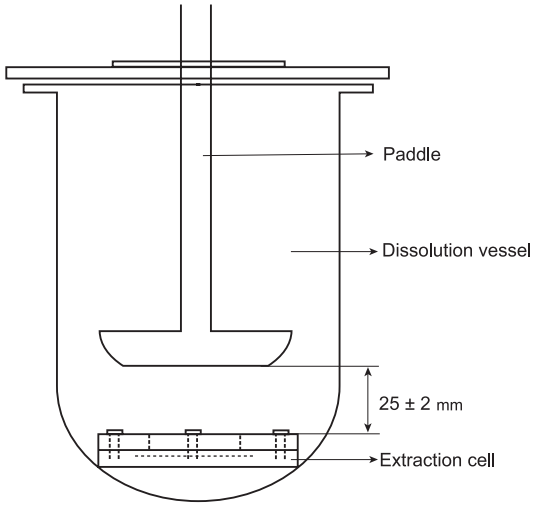

Figure 2.9.4.-4. – *Paddle over extraction cell*

3. ROTATING CYLINDER METHOD

Equipment. Use the assembly of the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*). Replace the paddle and shaft with a stainless steel cylinder stirring element (*cylinder*) (see Figure 2.9.4.-5). The patch is placed on the *cylinder* at the beginning of each test. The distance between the inside bottom of the vessel and the *cylinder* is maintained at 25 ± 2 mm during the test. The temperature is maintained at 32 ± 0.5 °C. The vessel is covered during the test to minimise evaporation.

Procedure. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Remove the protective liner from the patch and place the adhesive side on a piece of suitable inert porous membrane that is at least 1 cm larger on all sides than the patch. Place the patch on a clean surface with the membrane in contact with this surface. Two systems for adhesion to the *cylinder* may be used:

– apply a suitable adhesive to the exposed membrane borders and, if necessary, to the back of the patch,
– apply a double-sided adhesive tape to the external wall of the *cylinder*.

Using gentle pressure, carefully apply the non-adhesive side of the patch to the *cylinder*, so that the release surface is in contact with the dissolution medium and the long axis of the patch fits around the circumference of the *cylinder*.

The system for adhesion used is previously tested for absence of interference with the assay and of adsorption of the active ingredient(s).

Place the *cylinder* in the apparatus, and immediately rotate the *cylinder* at 100 r/min, for example. At determined intervals, withdraw a sample of dissolution medium from a zone midway between the surface of the dissolution medium and the top of the rotating *cylinder*, and not less than 1 cm from the vessel wall.

Perform the assay on each sample as directed in the individual monograph, correcting for any volume withdrawn, as necessary. Repeat the test with additional patches.

Interpretation. The requirements are met if the quantity of active ingredient(s) released from the patch, expressed as the amount per surface area per time unit, is within the prescribed limits at the defined sampling times.

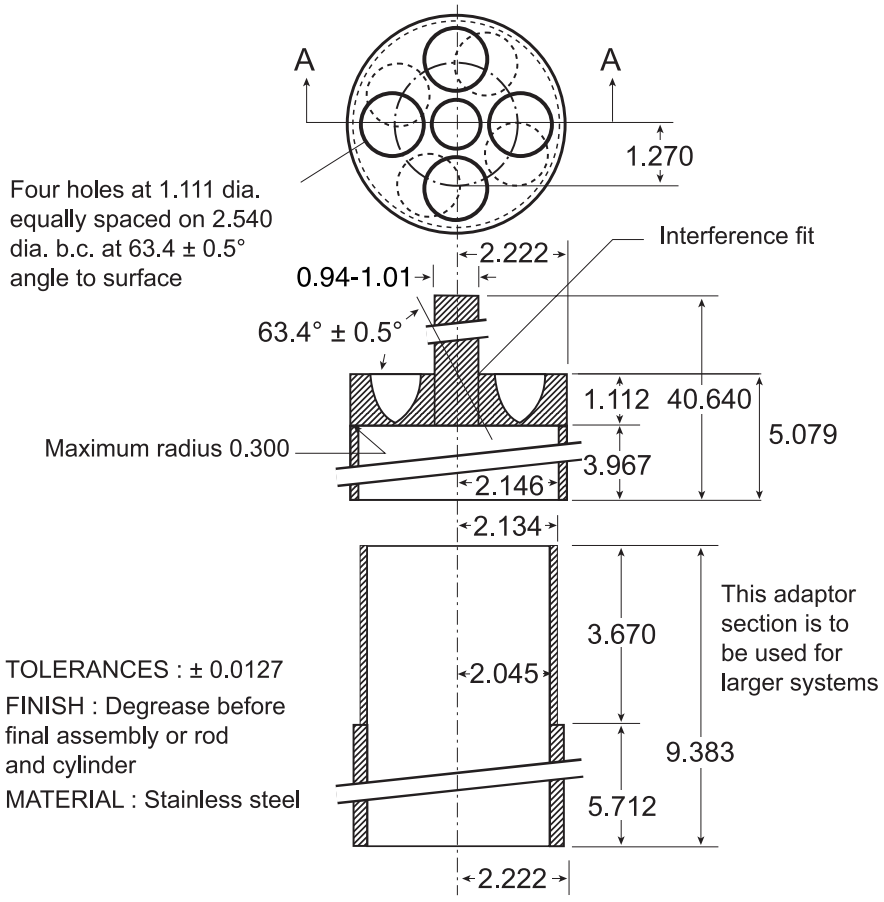

Figure 2.9.4.-5. – *Cylinder stirring element*
Dimensions in centimetres

2.9.5. UNIFORMITY OF MASS OF SINGLE-DOSE PREPARATIONS

Weigh individually 20 units taken at random or, for single-dose preparations presented in individual containers, the contents of 20 units, and determine the average mass. Not more than 2 of the individual masses deviate from the average mass by more than the percentage deviation shown in Table 2.9.5.-1 and none deviates by more than twice that percentage.

For capsules and powders for parenteral use, proceed as described below.

CAPSULES

Weigh an intact capsule. Open the capsule without losing any part of the shell and remove the contents as completely as possible. For soft shell capsules, wash the shell with a suitable solvent and allow to stand until the odour of the solvent is no longer perceptible. Weigh the shell. The mass of the contents is the difference between the weighings. Repeat the procedure with another 19 capsules.

Table 2.9.5.-1

Pharmaceutical Form	Average Mass	Percentage deviation
Tablets (uncoated and film-coated)	80 mg or less	10
	More than 80 mg and less than 250 mg	7.5
	250 mg or more	5
Capsules, granules (uncoated, single-dose) and powders (single-dose)	Less than 300 mg	10
	300 mg or more	7.5
Powders for parenteral use* (single-dose)	More than 40 mg	10
Suppositories and pessaries	All masses	5
Powders for eye-drops and powders for eye lotions (single-dose)	Less than 300 mg	10
	300 mg or more	7.5

* When the average mass is equal to or below 40 mg, the preparation is not submitted to the test for uniformity of mass but to the test for uniformity of content of single-dose preparations (*2.9.6*).

POWDERS FOR PARENTERAL USE

Remove any paper labels from a container and wash and dry the outside. Open the container and without delay weigh the container and its contents. Empty the container as completely as possible by gentle tapping, rinse it if necessary with *water R* and then with *alcohol R* and dry at 100-105 °C for 1 h, or, if the nature of the container precludes heating at this temperature, dry at a lower temperature to constant mass. Allow to cool in a desiccator and weigh. The mass of the contents is the difference between the weighings. Repeat the procedure with another 19 containers.

01/2008:20906

2.9.6. UNIFORMITY OF CONTENT OF SINGLE-DOSE PREPARATIONS

The test for uniformity of content of single-dose preparations is based on the assay of the individual contents of active substance(s) of a number of single-dose units to determine whether the individual contents are within limits set with reference to the average content of the sample.

The test is not required for multivitamin and trace-element preparations and in other justified and authorised circumstances.

Method. Using a suitable analytical method, determine the individual contents of active substance(s) of 10 dosage units taken at random.

Apply the criteria of test A, test B or test C as specified in the monograph for the dosage form in question.

TEST A

Tablets, powders for parenteral use, ophthalmic inserts, suspensions for injection. The preparation complies with the test if each individual content is between 85 per cent and 115 per cent of the average content. The preparation fails to comply with the test if more than one individual content is outside these limits or if one individual content is outside the limits of 75 per cent to 125 per cent of the average content.

If one individual content is outside the limits of 85 per cent to 115 per cent but within the limits of 75 per cent to 125 per cent, determine the individual contents of another 20 dosage units taken at random. The preparation complies with the test if not more than one of the individual contents of the 30 units is outside 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content.

TEST B

Capsules, powders other than for parenteral use, granules, suppositories, pessaries. The preparation complies with the test if not more than one individual content is outside the limits of 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content. The preparation fails to comply with the test if more than 3 individual contents are outside the limits of 85 per cent to 115 per cent of the average content or if one or more individual contents are outside the limits of 75 per cent to 125 per cent of the average content.

If 2 or 3 individual contents are outside the limits of 85 per cent to 115 per cent but within the limits of 75 per cent to 125 per cent, determine the individual contents of another 20 dosage units taken at random. The preparation complies with the test if not more than 3 individual contents of the 30 units are outside the limits of 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content.

TEST C

Transdermal patches. The preparation complies with the test if the average content of the 10 dosage units is between 90 per cent and 110 per cent of the content stated on the label and if the individual content of each dosage unit is between 75 per cent and 125 per cent of the average content.

01/2008:20907

2.9.7. FRIABILITY OF UNCOATED TABLETS

This chapter provides guidelines for the friability determination of compressed, uncoated tablets. The test procedure presented in this chapter is generally applicable to most compressed tablets. Measurement of tablet friability supplements other physical strength measurements, such as tablet breaking force.

Use a drum, with an internal diameter between 283-291 mm and a depth between 36-40 mm, of transparent synthetic polymer with polished internal surfaces, and subject to minimum static build-up (see Figure 2.9.7.-1.). One side of

the drum is removable. The tablets are tumbled at each turn of the drum by a curved projection with an inside radius between 75.5-85.5 mm that extends from the middle of the drum to the outer wall. The outer diameter of the central ring is between 24.5-25.5 mm. The drum is attached to the horizontal axis of a device that rotates at 25 ± 1 rpm. Thus, at each turn the tablets roll or slide and fall onto the drum wall or onto each other.

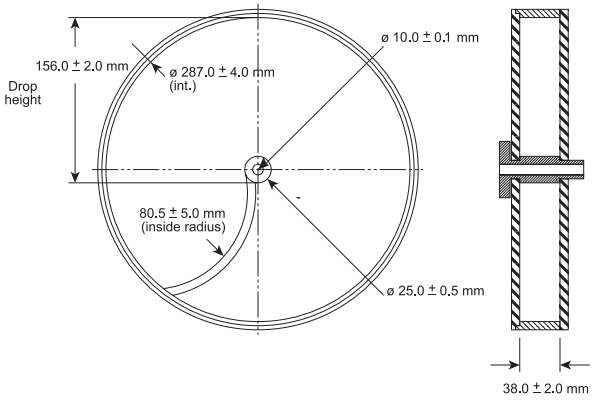

Figure 2.9.7.-1. — *Tablet friability apparatus*

For tablets with a unit mass equal to or less than 650 mg, take a sample of whole tablets corresponding as near as possible to 6.5 g. For tablets with a unit mass of more than 650 mg, take a sample of 10 whole tablets. The tablets are carefully dedusted prior to testing. Accurately weigh the tablet sample, and place the tablets in the drum. Rotate the drum 100 times, and remove the tablets. Remove any loose dust from the tablets as before, and accurately weigh.

Generally, the test is run once. If obviously cracked, cleaved, or broken tablets are present in the tablet sample after tumbling, the sample fails the test. If the results are difficult to interpret or if the weight loss is greater than the targeted value, the test is repeated twice and the mean of the 3 tests determined. A maximum loss of mass (obtained from a single test or from the mean of 3 tests) not greater than 1.0 per cent is considered acceptable for most products.

If tablet size or shape causes irregular tumbling, adjust the drum base so that the base forms an angle of about 10° with the horizontal and the tablets no longer bind together when lying next to each other, which prevents them from falling freely.

Effervescent tablets and chewable tablets may have different specifications as far as friability is concerned. In the case of hygroscopic tablets, a humidity-controlled environment is required for testing.

A drum with dual scooping projections, or apparatus with more than one drum, for the running of multiple samples at one time, are also permitted.

01/2008:20908

2.9.8. RESISTANCE TO CRUSHING OF TABLETS

This test is intended to determine, under defined conditions, the resistance to crushing of tablets, measured by the force needed to disrupt them by crushing.

APPARATUS

The apparatus consists of 2 jaws facing each other, one of which moves towards the other. The flat surfaces of the jaws are perpendicular to the direction of movement. The crushing surfaces of the jaws are flat and larger than the zone of contact with the tablet. The apparatus is calibrated using a system with a precision of 1 newton.

OPERATING PROCEDURE

Place the tablet between the jaws, taking into account, where applicable, the shape, the break-mark and the inscription; for each measurement orient the tablet in the same way with respect to the direction of application of the force. Carry out the measurement on 10 tablets, taking care that all fragments of tablets have been removed before each determination.

This procedure does not apply when fully automated equipment is used.

EXPRESSION OF RESULTS

Express the results as the mean, minimum and maximum values of the forces measured, all expressed in newtons.

Indicate the type of apparatus and, where applicable, the orientation of the tablets.

01/2008:20909

2.9.9. MEASUREMENT OF CONSISTENCY BY PENETROMETRY

This test is intended to measure, under determined and validated conditions, the penetration of an object into the product to be examined in a container with a specified shape and size.

APPARATUS

The apparatus consists of a penetrometer made up of a stand and a penetrating object. A suitable apparatus is shown in Figure 2.9.9.-1.

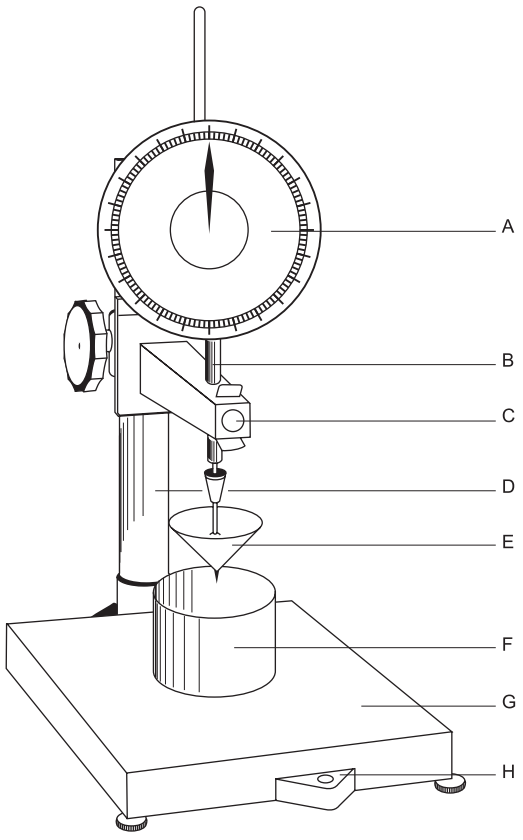

Figure 2.9.9.-1. — *Penetrometer*

A. Scale showing the depth of penetration, graduated in tenths of millimetres.

B. Vertical shaft to maintain and guide the penetrating object.

C. Device to retain and to release the penetrating object automatically and for a constant time.

D. Device to ensure that the penetrating object is vertical and that the base is horizontal.

E. Penetrating object (see Figures 2.9.9.-2 and 3).

F. Container.

G. Horizontal base.

H. Control for the horizontal base.

The stand is made up of:

– a vertical shaft to maintain and guide the penetrating object,

– a horizontal base,

– a device to ensure that the penetrating object is vertical,

– a device to check that the base is horizontal,

– a device to retain and release the penetrating object,

– a scale showing the depth of penetration, graduated in tenths of a millimetre.

The penetrating object, made of a suitable material, has a smooth surface, and is characterised by its shape, size and mass.

Suitable penetrating objects are shown in Figures 2.9.9.-2 and 2.9.9.-3.

PROCEDURE

Prepare the test samples by one of the following procedures:

A. Carefully and completely fill three containers, without forming air bubbles. Level if necessary to obtain a flat surface. Store the samples at 25 ± 0.5 °C for 24 h, unless otherwise prescribed.

B. Store three samples at 25 ± 0.5 °C for 24 h. Apply a suitable shear to the samples for 5 min. Carefully and completely fill three containers, without forming air bubbles, and level if necessary to obtain a flat surface.

C. Melt three samples and carefully and completely fill three containers, without forming air bubbles. Store the samples at 25 ± 0.5 °C for 24 h, unless otherwise prescribed.

Determination of penetration. Place the test sample on the base of the penetrometer. Verify that its surface is perpendicular to the vertical axis of the penetrating object. Bring the temperature of the penetrating object to 25 ± 0.5 °C and then adjust its position such that its tip just touches the surface of the sample. Release the penetrating object and hold it free for 5 s. Clamp the penetrating object and measure the depth of penetration. Repeat the test with the two remaining containers.

EXPRESSION OF THE RESULTS

The penetration is expressed in tenths of a millimetre as the arithmetic mean of the three measurements. If any of the individual results differ from the mean by more than 3 per cent, repeat the test and express the results of the six measurements as the mean and the relative standard deviation.

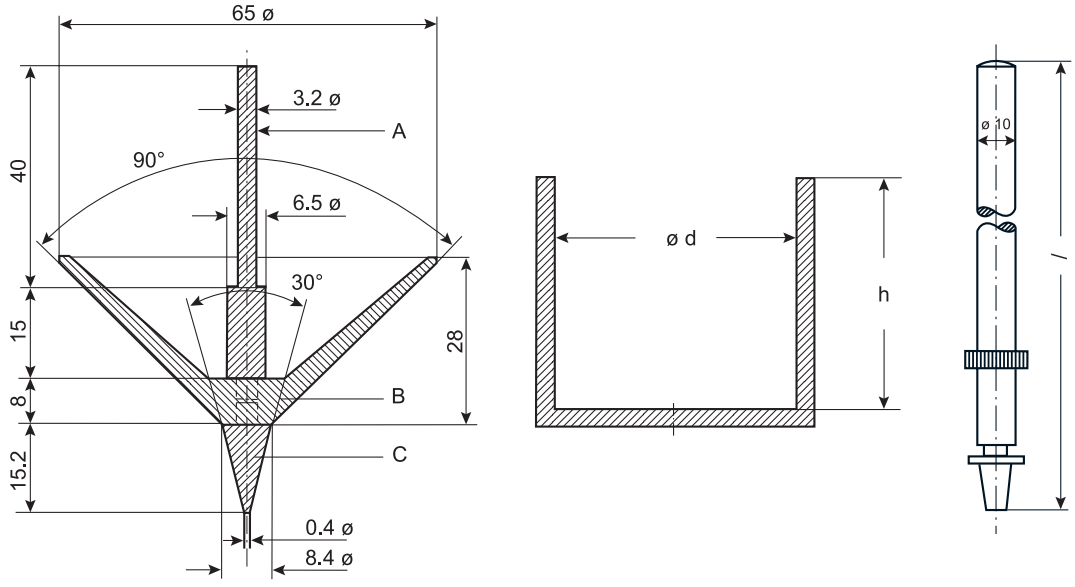

Figure 2.9.9.-2. – *Cone (m = 102.5 g), suitable container (d = 102 mm or 75 mm, h ≥ 62 mm) and shaft (l = 162 mm; m = 47.5 g).*

01/2008:20910

2.9.10. ETHANOL CONTENT AND ALCOHOLIMETRIC TABLES

This method is intended only for the examination of liquid pharmaceutical preparations containing ethanol. These preparations also contain dissolved substances which must be separated from the ethanol to be determined by distillation. When distillation would distil volatile substances other than ethanol and water the appropriate precautions are stated in the monograph.

The ethanol content of a liquid is expressed as the number of volumes of ethanol contained in 100 volumes of the liquid, the volumes being measured at 20 ± 0.1 °C. This is known as the “percentage of ethanol by volume” (per cent *V/V*). The content may also be expressed in grams of ethanol per 100 g of the liquid. This is known as the “percentage of ethanol by mass” (per cent *m/m*).

The relation between the density at 20 ± 0.1 °C, the relative density (corrected to vacuum) and the ethanol content of a mixture of water and ethanol is given in the tables of the International Organisation for Legal Metrology (1972), International Recommendation No. 22.

Apparatus. The apparatus (see Figure 2.9.10.-1) consists of a round-bottomed flask (*A*) fitted with a distillation head (*B*) with a steam trap and attached to a vertical condenser (*C*). The latter is fitted at its lower part with a tube (*D*) which carries the distillate into the lower part of a 100 ml or 250 ml volumetric flask. The volumetric flask is immersed in a mixture of ice and water (*E*) during the distillation. A disc having a circular aperture 6 cm in diameter is placed under flask (*A*) to reduce the risk of charring of any dissolved substances.

Method

Pycnometer method. Transfer 25.0 ml of the preparation to be examined, measured at 20 ± 0.1 °C, to the distillation flask. Dilute with 100 ml to 150 ml of *distilled water R* and add a few pieces of pumice. Attach the distillation head and condenser. Distil and collect not less than 90 ml of distillate in a 100 ml volumetric flask. Adjust the temperature to 20 ± 0.1 °C and dilute to 100.0 ml with *distilled water R* at 20 ± 0.1 °C. Determine the relative density at 20 ± 0.1 °C using a pycnometer.

Table 2.9.10.-1. - *Relationship between density, relative density and ethanol content*

ρ_{20} (kg·m^{-3})	Relative density of the distillate measured in air d_{20}^{20}	Ethanol content in per cent *V/V* at 20 °C

994.0	0.9958	2.86
994.5	0.9963	2.51
995.0	0.9968	2.16
995.5	0.9973	1.82
996.0	0.9978	1.47
996.5	0.9983	1.13
997.0	0.9988	0.80
997.5	0.9993	0.46
998.0	0.9998	0.13

The values indicated in Table 2.9.10.-1, column 3, are multiplied by four to obtain the percentage of ethanol by volume (*V/V*) contained in the preparation. After calculation of the ethanol content using the Table, round off the result to one decimal place.

Hydrometer method. Transfer 50.0 ml of the preparation to be examined, measured at 20 ± 0.1 °C, to the distillation flask, add 200 ml to 300 ml of *distilled water R* and distil, as described above, into a volumetric flask until at least 180 ml has been collected. Adjust the temperature to 20 ± 0.1 °C and dilute to 250.0 ml with *distilled water R* at 20 ± 0.1 °C.

Transfer the distillate to a cylinder whose diameter is at least 6 mm wider than the bulb of the hydrometer. If the volume is insufficient, double the quantity of the sample and dilute the distillate to 500.0 ml with *distilled water R* at 20 ± 0.1 °C.

Multiply the strength by five to allow for the dilution during the determination. After calculation of the ethanol content using the Table 2.9.10.-1 round off the result to one decimal place.

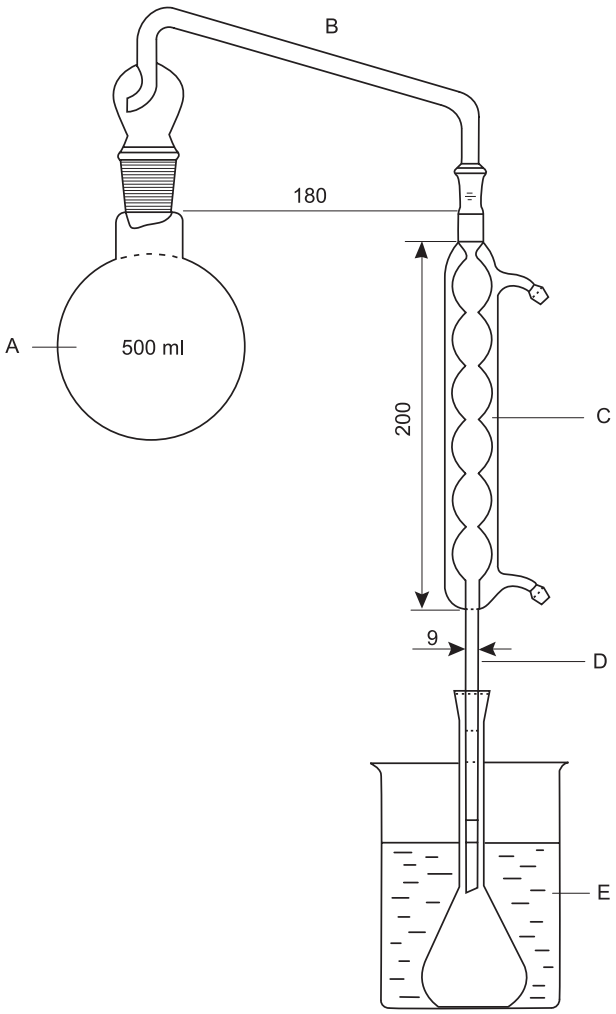

Figure 2.9.10.-1. – *Apparatus for the determination of ethanol content*
Dimensions in millimetres

2.9.11. TEST FOR METHANOL AND 2-PROPANOL

Examine by gas chromatography (*2.2.28*).

Internal standard solution. Prepare a solution containing 2.5 per cent *V/V* of *propanol R* in *ethanol R1*.

Test solution (a). To a certain amount of the distillate add 2.0 ml of the internal standard solution; adjust the ethanol content (*2.9.10*) to 10.0 per cent *V/V* by dilution to 50 ml with *water R* or addition of *ethanol R1*.

Test solution (b). Adjust the ethanol content (*2.9.10*) of a certain amount of the distillate to 10.0 per cent *V/V* by dilution to 50 ml with *water R* or addition of *ethanol R1*.

Reference solution (a). Prepare 50 ml of a solution containing 2.0 ml of the internal standard solution, 3.0 ml of *ethanol R1*, 0.05 per cent *V/V* of *2-propanol R* and sufficient *anhydrous methanol R* to give a total of 0.05 per cent *V/V* of methanol taking into account the methanol content of *ethanol R1*.

Reference solution (b). Prepare a 10.0 per cent *V/V* solution of *ethanol R1* containing 0.0025 per cent *V/V* of each *methanol R* and *2-propanol R*.

Column:

– *material*: fused silica,
– *size*: *l* = 30 m, Ø = 0.53 mm,
– *stationary phase*: *poly[(cyanopropyl)(phenyl)][dimethyl]siloxane R* (film thickness 3 µm).

Carrier gas: *helium for chromatography R*.

Flow rate: 2 ml/min.

Split ratio: 1:10.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 5	35
	5 - 15	35 - 85
Injection port		250
Detector		250

Detection: flame ionisation.

Injection: 1.0 µl.

System suitability:

– *propanol*: there is no peak corresponding to propanol in the chromatogram obtained with test solution (b),
– *peak-to-valley ratio*: minimum 15, where H_p = height above the baseline of the peak due to 2-propanol and H_v = height above the baseline of the lowest point of the curve separating this peak from the peak due to ethanol in the chromatogram obtained with the reference solution (a),
– *signal-to-noise ratio*: minimum 10 for the peaks due to methanol and 2-propanol in the chromatogram obtained with reference solution (b).

The content of methanol and 2-propanol is calculated with reference to the original sample.

01/2008:20912

2.9.12. SIEVE TEST

The degree of fineness of a powder may be expressed by reference to sieves that comply with the specifications for non-analytical sieves (*2.1.4*).

Where the degree of fineness of powders is determined by sieving, it is defined in relation to the sieve number(s) used either by means of the following terms or, where such terms cannot be used, by expressing the fineness of the powder as a percentage *m/m* passing the sieve(s) used.

The following terms are used in the description of powders:

Coarse powder. Not less than 95 per cent by mass passes through a number 1400 sieve and not more than 40 per cent by mass passes through a number 355 sieve.

Moderately fine powder. Not less than 95 per cent by mass passes through a number 355 sieve and not more than 40 per cent by mass passes through a number 180 sieve.

Fine powder. Not less than 95 per cent by mass passes through a number 180 sieve and not more than 40 per cent by mass passes through a number 125 sieve.

Very fine powder. Not less than 95 per cent by mass passes through a number 125 sieve and not more than 40 per cent by mass passes through a number 90 sieve.

If a single sieve number is given, not less than 97 per cent of the powder passes through the sieve of that number, unless otherwise prescribed.

Assemble the sieves and operate in a suitable manner until sifting is practically complete. Weigh the separated fractions of the powder.

01/2008:20914

2.9.14. SPECIFIC SURFACE AREA BY AIR PERMEABILITY

The test is intended for the determination of the specific surface area of dry powders expressed in square metres per gram in the sub-sieve region. The effect of molecular flow ("slip flow") which may be important when testing powders consisting of particles less than a few micrometres is not taken into account in the equation used to calculate the specific surface area.

APPARATUS

The apparatus consists of the following parts:

(a) a *permeability cell* (see Figure 2.9.14.-1), which consists of a cylinder with an inner diameter of 12.6 ± 0.1 mm (*A*), constructed of glass or non-corroding metal. The bottom of the cell forms an airtight connection (for example, via an adapter) with the manometer (Figure 2.9.14.-2). A ledge 0.5 mm to 1 mm in width is located 50 ± 15 mm from the top of the cell. It is an integral part of the cell or firmly fixed so as to be airtight. It supports a perforated metal disk (*B*), constructed of non-corroding metal. The disk has a thickness of 0.9 ± 0.1 mm and is perforated with thirty to forty holes 1 mm in diameter evenly distributed over this area.

The plunger (*C*) is made of non-corroding metal and fits into the cell with a clearance of not more than 0.1 mm. The bottom of the plunger has sharp square edges at right angles to the principal axis. There is an air vent 3 mm long and 0.3 mm deep on one side of the plunger. The top of the plunger has a collar such that when the plunger is placed in the cell and the collar is brought into contact with the top of the cell, the distance between the bottom of the plunger and the top of the perforated disk (*B*) is 15 ± 1 mm.

The filter paper disks (*D*) have smooth edges and the same diameter as the inside of the cell.

(b) a *U-tube manometer* (*E*) (Figure 2.9.14.-2) is made of nominal 9 mm outer diameter and 7 mm inner diameter glass tubing with standard walls. The top of one arm of the manometer forms an airtight connection with the permeability cell (*F*). The manometer arm connected to the permeability cell has a line etched around the tube at 125 mm to 145 mm below the top of the side outlet and three other lines at distances of 15 mm, 70 mm and 110 mm above that line (*G*). The side outlet 250 mm to 305 mm above the bottom of the manometer is used to evacuate the manometer arm connected to the permeability cell. A tap is provided on the side outlet not more than 50 mm from the manometer arm.

The manometer is mounted firmly in such a manner that the arms are vertical. It is filled to the lowest mark with *dibutyl phthalate R* containing a lipophilic dye.

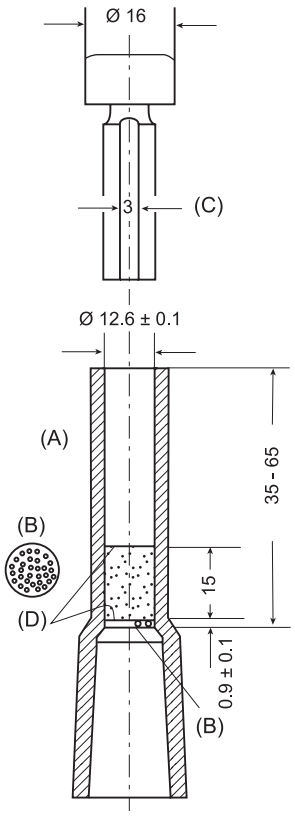

Figure 2.9.14.-1. – *Permeability cell*
Dimensions in millimetres

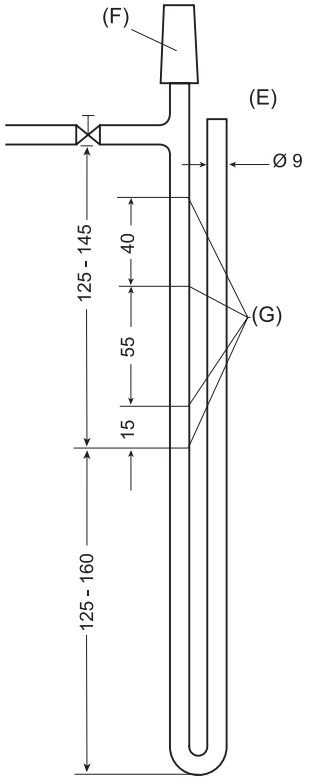

Figure 2.9.14.-2. – *Manometer*
Dimensions in millimetres

METHOD

If prescribed, dry the powder to be examined and sift through a suitable sieve (for example no. 125) to disperse agglomerates. Calculate the mass (*M*) of the powder to be used from the following expression:

$$M = V \times \rho \times (1 - \varepsilon) \qquad (1)$$

V = bulk volume of the compacted bed of powder,

ρ = density of the substance to be examined in grams per millilitre,

ϵ = porosity of the compacted bed of powder.

Assume first a porosity of 0.5 and introduce this value in Eq. 1 to calculate the mass (*M*) of the powder to be examined.

Place a filter paper disk on top of the perforated metal disk (*B*). Weigh the calculated mass (*M*) of the powder to be examined to the nearest 1 mg. Carefully transfer the powder into the cleaned, tared permeability cell and carefully tap the cell so that the surface of the powder bed is level and cover it with a second filter paper disk. Slowly compact the powder by means of the plunger, avoiding rotary movement. Maintain the pressure until the plunger is completely inserted into the permeability cell. If this is not possible, decrease the quantity of the powder used. If, on the contrary, there is not enough resistance, increase the quantity of the powder. In this case calculate the porosity again. After at least 10 s, remove the plunger.

Attach the permeability cell to the tube of the manometer by means of an airtight connection. Evacuate the air from the manometer by means of a rubber bulb until the level of the coloured liquid is at the highest mark. Close the tap and check that the apparatus is airtight by closing the upper end of the cell, for example with a rubber stopper. Remove the stopper and, using a timer, measure the time taken for the liquid to fall from the second to the third mark.

Using the measured flow time, calculate the specific surface area (*S*), expressed in square metres per gram, from the following expression:

$$S = \frac{K \times \sqrt{\varepsilon^3} \times \sqrt{t}}{\rho \times (1 - \varepsilon) \times \sqrt{\eta}} \qquad (2)$$

t = flow time in seconds,

η = dynamic viscosity of air in millipascal seconds (see Table 2.9.14.-1),

K = apparatus constant determined according to Equation (4),

ρ = density of the substance to be examined in grams per millilitre,

ϵ = porosity of the compacted bed of powder.

CALIBRATION OF THE APPARATUS

The bulk volume of the compacted bed of powder is determined by the mercury displacement method as follows:

Place two filter paper disks in the permeability cell, pressing down the edges with a rod slightly smaller than the cell diameter until the filter disks lie flat on the perforated metal disk; fill the cell with mercury, removing any air bubbles adhering to the wall of the cell and wipe away the excess to create a plane surface of mercury at the top of the cell. If the cell is made of material that will amalgamate, grease the cell and the metal disk first with a thin layer of liquid paraffin. Pour out the mercury into a tared beaker and determine the mass (M_A) and the temperature of the mercury.

Make a compacted bed using the reference powder and again fill the cell with mercury with a planar surface at the top of the cell. Pour out the mercury in a tared beaker and again determine the mass of the mercury (M_B). Calculate the bulk volume (V) of the compacted bed of powder from the following expression:

$$V = \frac{M_A - M_B}{\rho_{Hg}} \qquad (3)$$

$M_A - M_B$ = difference between the determined masses of mercury in grams,

ρ_{Hg} = density of mercury at the determined temperature in grams per millilitre.

Repeat the procedure twice, changing the powder each time; the range of values for the calculated volume (V) is not greater than 0.01 ml. Use the mean value of the three determined volumes for the calculations.

The apparatus constant *K* is determined using a reference powder with known specific surface area and density as follows:

Calculate the required quantity of the reference powder to be used (Eq. 1) using the stated density and the determined volume of the compacted powder bed (Eq. 3).

Homogenise and loosen up the powder by shaking it for 2 min in a 100 ml bottle. Prepare a compacted powder bed and measure the flow time of air as previously described. Calculate the apparatus constant (K) from the following expression:

$$K = \frac{S_{sp} \times \rho \times (1 - \varepsilon) \times \sqrt{\eta}}{\sqrt{\varepsilon^3} \times \sqrt{t}} \qquad (4)$$

S_{sp} = stated specific surface area of the reference powder,

ρ = density of the substance to be examined in grams per millilitre,

ϵ = porosity of the compacted bed of powder,

t = flow time in seconds,

η = dynamic viscosity of air in millipascal seconds (see Table 2.9.14.-1).

The density of mercury and the viscosity of air over a range of temperatures are shown in Table 2.9.14.-1.

Table 2.9.14.-1.

Temperature (°C)	Density of mercury (g/ml)	Viscosity of air (η) (mPa·s)	$\sqrt{\eta}$
16	13.56	0.01800	0.1342

2.9.15. APPARENT VOLUME

The test for apparent volume is intended to determine under defined conditions the apparent volumes, before and after settling, the ability to settle and the apparent densities of divided solids (for example, powders, granules).

APPARATUS

The apparatus (see Figure 2.9.15.-1) consists of the following:

– a settling apparatus capable of producing in 1 min 250 ± 15 taps from a height of 3 ± 0.2 mm. The support for the graduated cylinder, with its holder, has a mass of 450 ± 5 g;

– a 250 ml graduated cylinder (2 ml intervals) with a mass of 220 ± 40 g.

METHOD

Into the dry cylinder, introduce without compacting 100.0 g (m g) of the substance to be examined. If this is not possible, select a test sample with an apparent volume between 50 ml and 250 ml and specify the mass in the expression of results. Secure the cylinder in its holder. Read the unsettled apparent volume V_0 to the nearest millilitre. Carry out 10, 500 and 1250 taps and read the corresponding volumes V_{10}, V_{500} and V_{1250}, to the nearest millilitre. If the difference between V_{500} and V_{1250} is greater than 2 ml, carry out another 1250 taps.

EXPRESSION OF THE RESULTS

a) Apparent volumes:

– apparent volume before settling or bulk volume: V_0 ml.

– apparent volume after settling or settled volume: V_{1250} ml or V_{2500} ml.

b) Ability to settle: difference V_{10} ml – V_{500} ml.

c) Apparent densities:

The apparent densities are expressed as follows:

– apparent density before settling or density of bulk product: m/V_0 (grams per millilitre) (poured density).

– apparent density after settling or density of settled product: m/V_{1250} or m/V_{2500} (grams per millilitre) (tapped density).

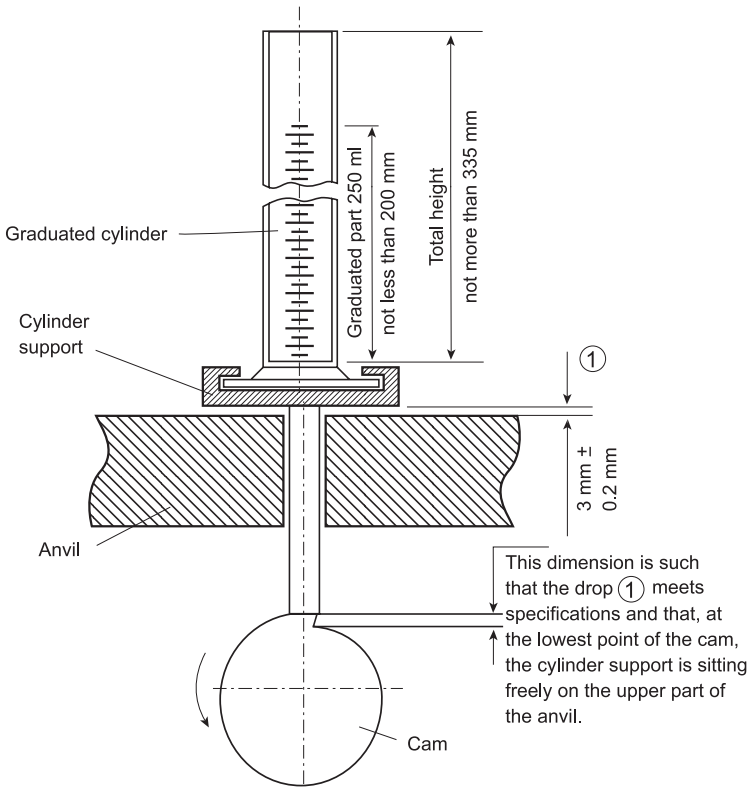

Figure 2.9.15.-1

01/2008:20916

2.9.16. FLOWABILITY

The test for flowability is intended to determine the ability of divided solids (for example, powders and granules) to flow vertically under defined conditions.

APPARATUS

According to the flow properties of the material to be tested, funnels with or without stem, with different angles and orifice diameters are used. Typical apparatuses are shown in Figures 2.9.16.-1 and 2.9.16.-2. The funnel is maintained upright by a suitable device. The assembly must be protected from vibrations.

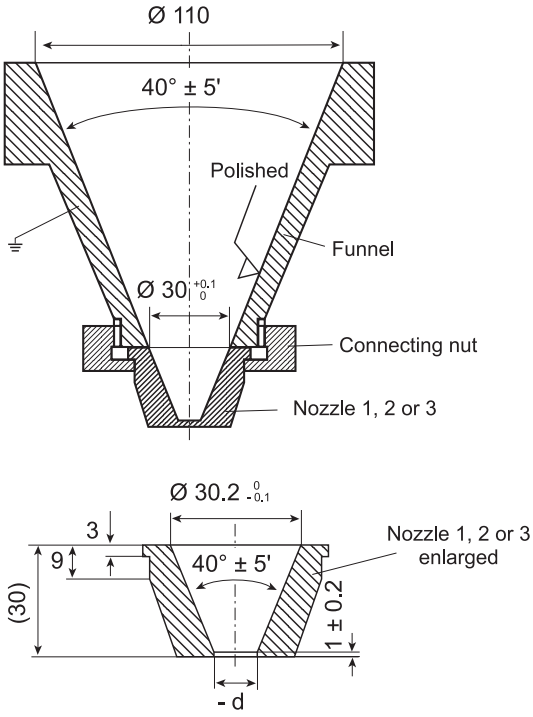
METHOD

Into a dry funnel, whose bottom opening has been blocked by suitable means, introduce without compacting a test sample weighed with 0.5 per cent accuracy. The amount of the sample depends on the apparent volume and the apparatus used. Unblock the bottom opening of the funnel and measure the time needed for the entire sample to flow out of the funnel. Carry out three determinations.

EXPRESSION OF RESULTS

The flowability is expressed in seconds and tenths of seconds, related to 100 g of sample.

The results depend on the storage conditions of the material to be tested.



The results can be expressed as the following:

a) the mean of the determinations, if none of the individual values deviates from the mean value by more than 10 per cent;

b) as a range, if the individual values deviate from the mean value by more than 10 per cent;

c) as a plot of the mass against the flow time;

d) as an infinite time, if the entire sample fails to flow through.

Nozzle	Diameter (*d*) of the outflow opening (millimetres)
1	10 ± 0.01
2	15 ± 0.01
3	25 ± 0.01

2.9.17. TEST FOR EXTRACTABLE VOLUME OF PARENTERAL PREPARATIONS

Suspensions and emulsions are shaken before withdrawal of the contents and before the determination of the density. Oily and viscous preparations may be warmed according to the instructions on the label, if necessary, and thoroughly shaken immediately before removing the contents. The contents are then cooled to 20-25 °C before measuring the volume.

SINGLE-DOSE CONTAINERS

Select 1 container if the nominal volume is 10 ml or more, 3 containers if the nominal volume is more than 3 ml and less than 10 ml, or 5 containers if the nominal volume is 3 ml or less. Take up individually the total contents of each container selected into a dry syringe of a capacity not exceeding 3 times the volume to be measured, and fitted with a 21-gauge needle not less than 2.5 cm in length. Expel any air bubbles from the syringe and needle, then discharge the contents of the syringe without emptying the needle into a standardised dry cylinder (graduated to contain rather than to deliver the designated volumes) of such size that the volume to be measured occupies at least 40 per cent of its graduated volume. Alternatively, the volume of the contents in millilitres may be calculated as the mass in grams divided by the density.

For containers with a nominal volume of 2 ml or less, the contents of a sufficient number of containers may be pooled to obtain the volume required for the measurement provided that a separate, dry syringe assembly is used for each container. The contents of containers holding 10 ml or more may be determined by opening them and emptying the contents directly into the graduated cylinder or tared beaker.

The volume is not less than the nominal volume in case of containers examined individually, or, in case of containers with a nominal volume of 2 ml or less, is not less than the sum of the nominal volumes of the containers taken collectively.

MULTI-DOSE CONTAINERS

For injections in multidose containers labelled to yield a specific number of doses of a stated volume, select one container and proceed as directed for single-dose containers using the same number of separate syringe assemblies as the number of doses specified.

The volume is such that each syringe delivers not less than the stated dose.

CARTRIDGES AND PREFILLED SYRINGES

Select 1 container if the nominal volume is 10 ml or more, 3 containers if the nominal volume is more than 3 ml and less than 10 ml, or 5 containers if the nominal volume is 3 ml or less. If necessary, fit the containers with the accessories required for their use (needle, piston, syringe) and transfer the entire contents of each container without emptying the needle into a dry tared beaker by slowly and constantly depressing the piston. Determine the volume in millilitres calculated as the mass in grams divided by the density.

The volume measured for each of the containers is not less than the nominal volume.

PARENTERAL INFUSIONS

Select one container. Transfer the contents into a dry measuring cylinder of such a capacity that the volume to be determined occupies at least 40 per cent of the nominal volume of the cylinder. Measure the volume transferred.

The volume is not less than the nominal volume.

01/2008:20918

2.9.18. PREPARATIONS FOR INHALATION: AERODYNAMIC ASSESSMENT OF FINE PARTICLES

This test is used to determine the fine particle characteristics of the aerosol clouds generated by preparations for inhalation.

Unless otherwise justified and authorised, one of the following apparatus and test procedures is used.

Stage mensuration is performed periodically together with confirmation of other dimensions critical to the effective operation of the impactor.

Re-entrainment (for apparatus D and E). To ensure efficient particle capture, coat each plate with glycerol, silicone oil or similar high viscosity liquid, typically deposited from a volatile solvent. Plate coating must be part of method validation and may be omitted where justified and authorised.

Mass balance. The total mass of the active substance is not less than 75 per cent and not more than 125 per cent of the average delivered dose determined during testing for uniformity of delivered dose. This is not a test of the inhaler but it serves to ensure that the results are valid.

APPARATUS A - GLASS IMPINGER

The apparatus is shown in Figure 2.9.18.-1 (see also Table 2.9.18.-1).

Table 2.9.18.-1. – *Component specification for apparatus A in Figure 2.9.18.-1*

Code	Item	Description	Dimensions*
A	Mouthpiece adaptor	Moulded rubber adapter for actuator mouthpiece.

* Dimensions in millimetres, unless otherwise stated.

Procedure for nebulisers

Introduce 7 ml and 30 ml of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the jet spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Connect a suitable pump fitted with a filter (of suitable pore size) to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min.

Introduce the liquid preparation for inhalation into the reservoir of the nebuliser. Fit the mouthpiece and connect it by means of an adapter to the device.

Switch on the pump of the apparatus and after 10 s switch on the nebuliser.

After 60 s, unless otherwise justified, switch off the nebuliser, wait for about 5 s and then switch off the pump of the apparatus. Dismantle the apparatus and wash the inner surface of the upper impingement chamber collecting the washings in a volumetric flask. Wash the inner surface of the lower impingement chamber collecting the washings in a second volumetric flask. Finally, wash the filter preceding the pump and its connections to the lower impingement chamber and combine the washings with those obtained from the lower impingement chamber. Determine the amount of active substance collected in each of the 2 flasks. Express the results for each of the 2 parts of the apparatus as a percentage of the total amount of active substance.

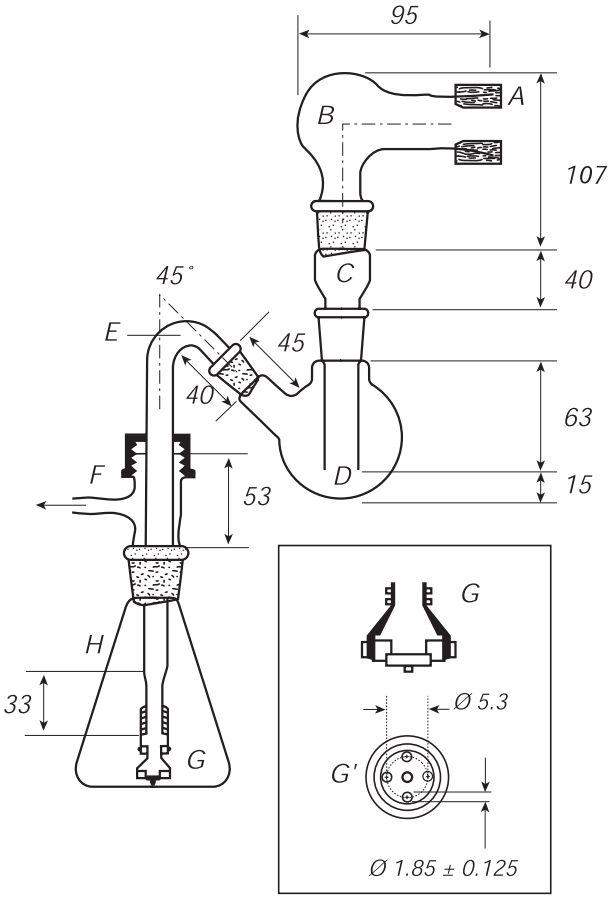

Figure 2.9.18.-1. – *Apparatus A: glass impinger*

Dimensions in millimetres (tolerances ± 1 mm unless otherwise prescribed)

Procedure for pressurised inhalers

Place the actuator adapter in position at the end of the throat so that the mouthpiece end of the actuator, when inserted to a depth of about 10 mm, lines up along the horizontal axis of the throat and the open end of the actuator, which accepts the pressurised container, is uppermost and in the same vertical plane as the rest of the apparatus.

Introduce 7 ml and 30 ml of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the lower jet-spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Connect a

suitable pump to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min.

Prime the metering valve by shaking for 5 s and discharging once to waste; after not less than 5 s, shake and discharge again to waste. Repeat a further 3 times.

Shake for about 5 s, switch on the pump to the apparatus and locate the mouthpiece end of the actuator in the adapter, discharge once immediately. Remove the assembled inhaler from the adapter, shake for not less than 5 s, relocate the mouthpiece end of the actuator in the adapter and discharge again. Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. After the final discharge wait for not less than 5 s and then switch off the pump. Dismantle the apparatus.

Wash the inner surface of the inlet tube to the lower impingement chamber and its outer surface that projects into the chamber with a suitable solvent, collecting the washings in the lower impingement chamber. Determine the content of active substance in this solution. Calculate the amount of active substance collected in the lower impingement chamber per discharge and express the results as a percentage of the dose stated on the label.

Procedure for powder inhalers

Introduce 7 ml and 30 ml of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the jet-spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Without the inhaler in place, connect a suitable pump to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min.

Prepare the inhaler for use and locate the mouthpiece in the apparatus by means of a suitable adapter. Switch on the pump for 5 s. Switch off the pump and remove the inhaler. Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. Dismantle the apparatus.

Wash the inner surface of the inlet tube to the lower impingement chamber and its outer surface that projects into the chamber with a suitable solvent, collecting the washings in the lower impingement chamber. Determine the content of active substance in this solution. Calculate the amount of active substance collected in the lower impingement chamber per discharge and express the results as a percentage of the dose stated on the label.

Fine particle dose and particle size distribution

APPARATUS C - MULTI-STAGE LIQUID IMPINGER

The multi-stage liquid impinger consists of impaction stages 1 (pre-separator), 2, 3 and 4 and an integral filter stage (stage 5), see Figures 2.9.18.-4/6. An impaction stage comprises an upper horizontal metal partition wall (B) through which a metal inlet jet tube (A) with its impaction plate (D) is protruding. A glass cylinder (E) with sampling port (F) forms the vertical wall of the stage, and a lower horizontal metal partition wall (G) through which the tube (H) connects to the next lower stage. The tube into stage 4 (U) ends in a multi-jet arrangement. The impaction plate (D) is secured in a metal frame (J) which is fastened by 2 wires (K) to a sleeve (L) secured on the jet tube. The horizontal face of the collection plate is perpendicular to the axis of the jet tube and centrally aligned. The upper surface of the impaction plate is slightly raised above the edge of the metal frame. A recess around the perimeter of the horizontal partition wall guides the position of the glass cylinder. The glass cylinders are sealed against the horizontal partition walls with gaskets (M) and clamped together by 6 bolts (N). The sampling ports are sealed by stoppers. The bottom-side of the lower partition wall of stage 4 has a concentrical protrusion fitted with a rubber O-ring (P) which seals against the edge of a filter placed in the filter holder. The filter holder (R) is constructed as a basin with a concentrical recess in which a perforated filter support (S) is flush-fitted. The filter holder is dimensioned for 76 mm diameter filters. The assembly of impaction stages is clamped onto the filter holder by 2 snap-locks (T). Connect an induction port (see Figure 2.9.18.-7) onto the stage 1 inlet jet tube of the impinger. A rubber O-ring on the jet tube provides an airtight connection to the induction port. A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port.

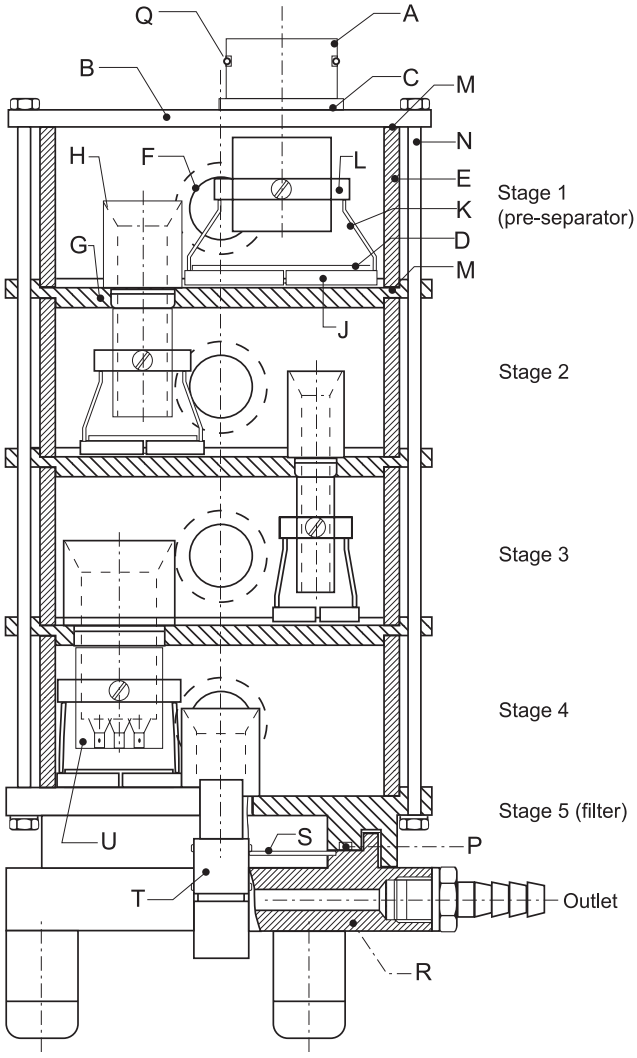

Figure 2.9.18.-4. – *Apparatus C: multi-stage liquid impinger*

Procedure for pressurised inhalers

Dispense 20 ml of a solvent, capable of dissolving the active substance into each of stages 1 to 4 and replace the stoppers. Tilt the apparatus to wet the stoppers, thereby neutralising electrostatic charge. Place a suitable filter capable of quantitatively collecting the active substance in stage 5 and assemble the apparatus. Place a suitable mouthpiece adapter in position at the end of the induction

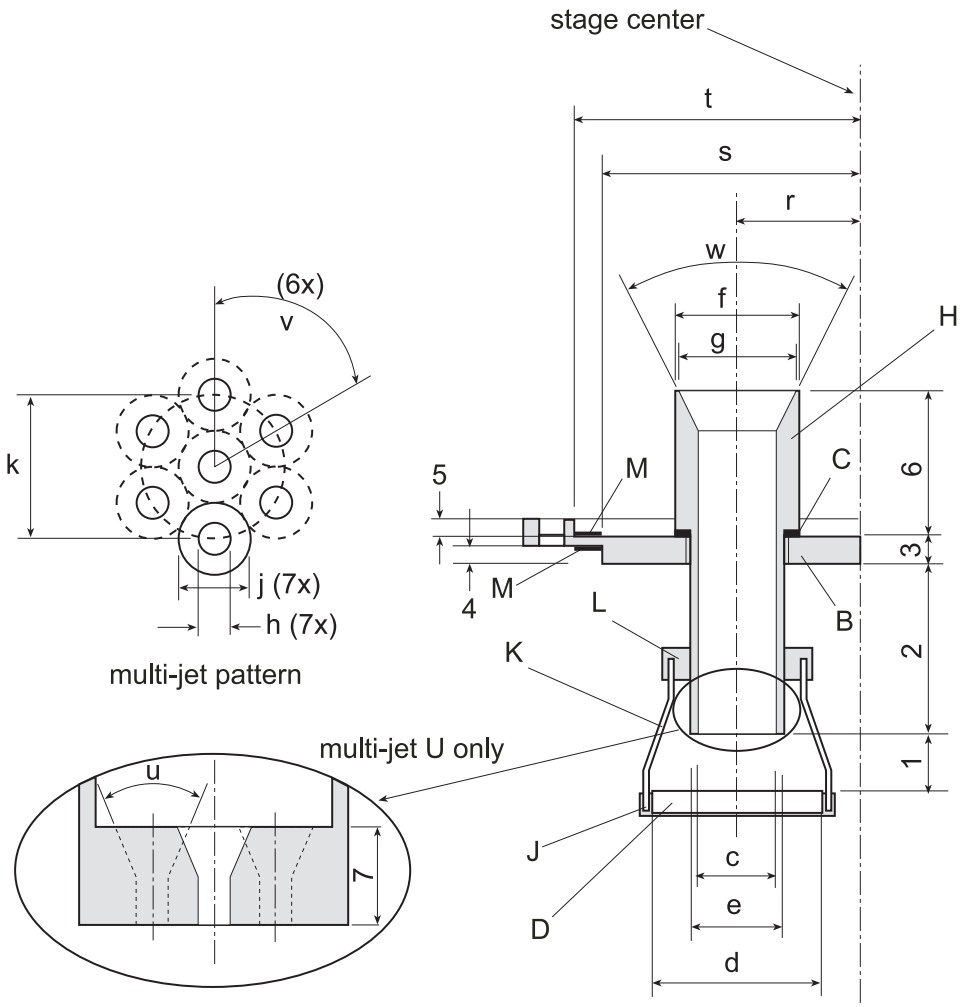

Figure 2.9.18.-5. – *Apparatus C: details of jet tube and impaction plate. Inserts show end of multi-jet tube U leading to stage 4. (Numbers and lowercase letters refer to Table 2.9.18.-3 and uppercase letters refer to Figure 2.9.18.-4).*

Dimensions in millimetres unless otherwise stated

port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port and the inhaler is positioned in the same orientation as intended for use. Connect a suitable vacuum pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 30 litres/min (± 5 per cent). Switch off the pump.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge 1 delivery to waste. Switch on the pump to the apparatus, locate the mouthpiece end of the actuator in the adapter and discharge

the inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the filter stage of the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. If necessary, rinse the inside of the inlet jet tube to stage 1 with solvent, allowing the solvent to flow into the stage. Extract the active substance from the inner walls and the collection plate of each of the 4 upper stages of the apparatus into the solution in the respective stage by carefully tilting and rotating the apparatus, observing that no liquid transfer occurs between the stages.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

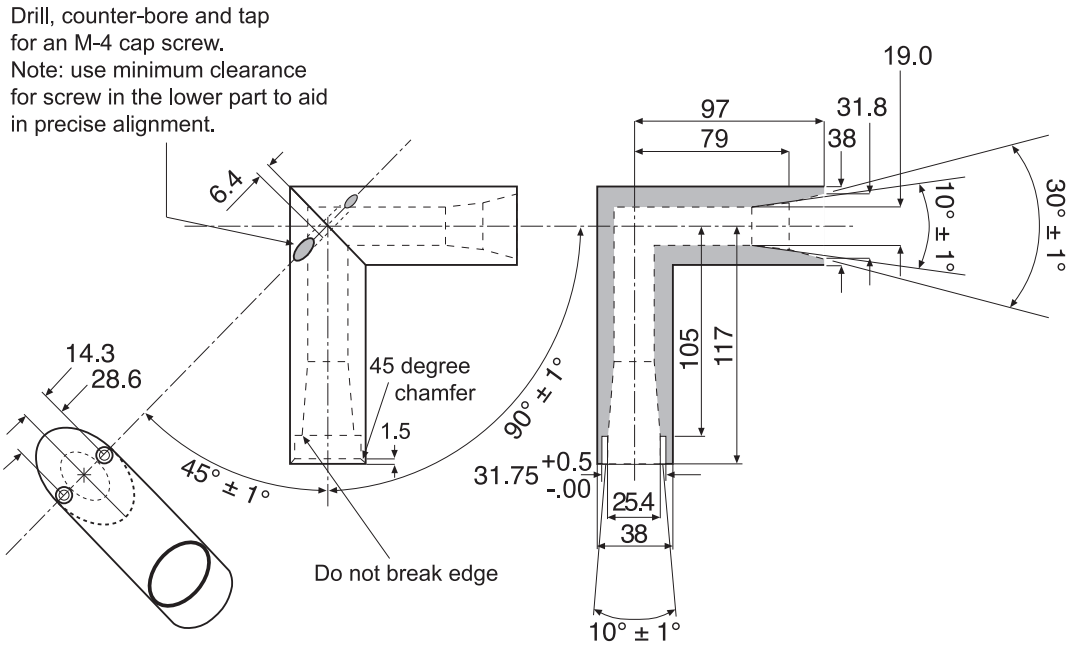
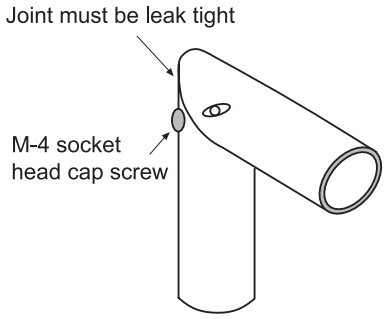
Procedure for powder inhalers



Place a suitable low resistance filter capable of quantitatively collecting the active substance in stage 5 and assemble the apparatus. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4. Unless otherwise defined, conduct the test at the flow rate, Q_{out}, used in the test for uniformity of delivered dose, drawing 4 litres of air from the mouthpiece of the inhaler and through the apparatus.



Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter (Q_{out}) using the ideal gas law. For a meter calibrated for the entering volumetric flow (Q_{in}), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

P_0 = atmospheric pressure,

ΔP = pressure drop over the meter.

Isometric view of induction port

Note

(1) Material may be aluminium, stainless steel or other suitable material.

(2) Machine from 38 mm bar stock.

(3) Bore 19 mm hole through bar.

(4) Cut tube to exact 45° as shown.

(5) The inner bores and tapers should be smooth – surface roughness Ra approx. 0.4 µm.

(6) Mill joining cads of stock to provide a liquid tight leak-free seal.

(7) Set up a holding fixture for aligning the inner 19 mm bore and for drilling and tapping M4 × 0.7 threads. There must be virtually no mismatch of the inner bores in the miter joint.

Figure 2.9.18.-7. – *Induction port*

Dimensions in millimetres unless otherwise stated

Adjust the flow control valve to achieve steady flow through the system at the required rate, Q_{out} (± 5 per cent). Switch off the pump. Ensure that critical flow occurs in the flow control valve by the following procedure.

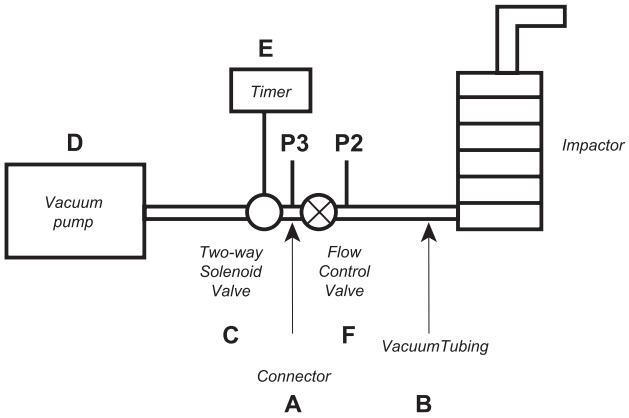


Figure 2.9.18.-8. – *Experimental set-up for testing powder inhalers*

Table 2.9.18.-4. – *Component specification for Figure 2.9.18.-8*

Code	Item	Description
A	Connector	ID ≥ 8 mm, e.g., short metal coupling, with low-diameter branch to P3.
B	Vacuum tubing	A length of suitable tubing having an ID ≥ 8 mm and an internal volume of 25 ± 5 ml.
C	2-way solenoid valve	A 2-way, 2-port solenoid valve having a minimum airflow resistance orifice with ID ≥ 8 mm and an opening time ≤ 100 ms. (e.g. type 256-A08, Bürkert GmbH, D-74653 Ingelfingen), or equivalent.
D	Vacuum pump	Pump must be capable of drawing the required flow rate through the assembled apparatus with the powder inhaler in the mouthpiece adapter (e.g. product type 1023, 1423 or 2565, Gast Manufacturing Inc., Benton Harbor, MI 49022), or equivalent. Connect the pump to the 2-way solenoid valve using short and/or wide (ID ≥ 10 mm) vacuum tubing and connectors to minimise pump capacity requirements.
E	Timer	Timer capable to drive the 2-way solenoid valve for the required duration (e.g. type G814, RS Components International, Corby, NN17 9RS, UK), or equivalent.
P2 P3	Pressure measurements	Determine under steady-state flow condition with an absolute pressure transducer.
F	Flow control valve	Adjustable regulating valve with maximum $C_v \geq 1$, (e.g. type 8FV12LNSS, Parker Hannifin plc., Barnstaple, EX31 1NP, UK), or equivalent.

With the inhaler in place and the test flow rate established, measure the absolute pressure on both sides of the control valve (pressure reading points P2 and P3 in Figure 2.9.18.-8). A ratio P3/P2 of less than or equal to 0.5 indicates critical flow. Switch to a more powerful pump and re-measure the test flow rate if critical flow is not indicated.

Dispense 20 ml of a solvent, capable of dissolving the active substance into each of the 4 upper stages of the apparatus and replace the stoppers. Tilt the apparatus to wet the stoppers, thereby neutralising electrostatic charge. Place a suitable mouthpiece adapter in position at the end of the induction port.

Prepare the powder inhaler for use according to patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

Dismantle the filter stage of the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. If necessary, rinse the inside of the inlet jet tube to stage 1 with solvent, allowing the solvent to flow into the stage. Extract the active substance from the inner walls and the collection plate of each of the 4 upper stages of the apparatus into the solution in the respective stage by carefully tilting and rotating the apparatus, observing that no liquid transfer occurs between the stages.

Using a suitable method of analysis, determine the amount of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

APPARATUS D - ANDERSEN CASCADE IMPACTOR

The Andersen 1 ACFM non-viable cascade impactor consists of 8 stages together with a final filter. Material of construction may be aluminium, stainless steel or other suitable material. The stages are clamped together and sealed with O-rings. Critical dimensions applied by the manufacturer of apparatus D are provided in Table 2.9.18.-5. In use, some occlusion and wear of holes will occur. In-use mensuration tolerances need to be justified. In the configuration used for pressurised inhalers (Figure 2.9.18.-9) the entry cone of the impactor is connected to an induction port (see Figure 2.9.18.-7). A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port.

In the configuration for powder inhalers, a pre-separator is placed above the top stage to collect large masses of non-respirable powder. It is connected to the induction port as shown in Figure 2.9.18.-10. To accommodate high flow rates through the impactor, the outlet nipple, used to connect the impactor to the vacuum system is enlarged to have an internal diameter of greater than or equal to 8 mm.

Table 2.9.18.-5. – *Critical dimensions for apparatus D*

Description	Number	Dimension (mm)
Stage 0 nozzle diameter	96	2.55 ± 0.025
Stage 1 nozzle diameter	96	1.89 ± 0.025
Stage 2 nozzle diameter	400	0.914 ± 0.0127
Stage 3 nozzle diameter	400	0.711 ± 0.0127
Stage 4 nozzle diameter	400	0.533 ± 0.0127
Stage 5 nozzle diameter	400	0.343 ± 0.0127
Stage 6 nozzle diameter	400	0.254 ± 0.0127
Stage 7 nozzle diameter	201	0.254 ± 0.0127

Procedure for pressurised inhalers

Assemble the Andersen impactor with a suitable filter in place. Ensure that the system is airtight. In that respect, follow the manufacturer's instructions. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port and the inhaler unit is positioned in the same orientation as the intended use. Connect a suitable pump to the outlet of the apparatus and adjust the air flow through

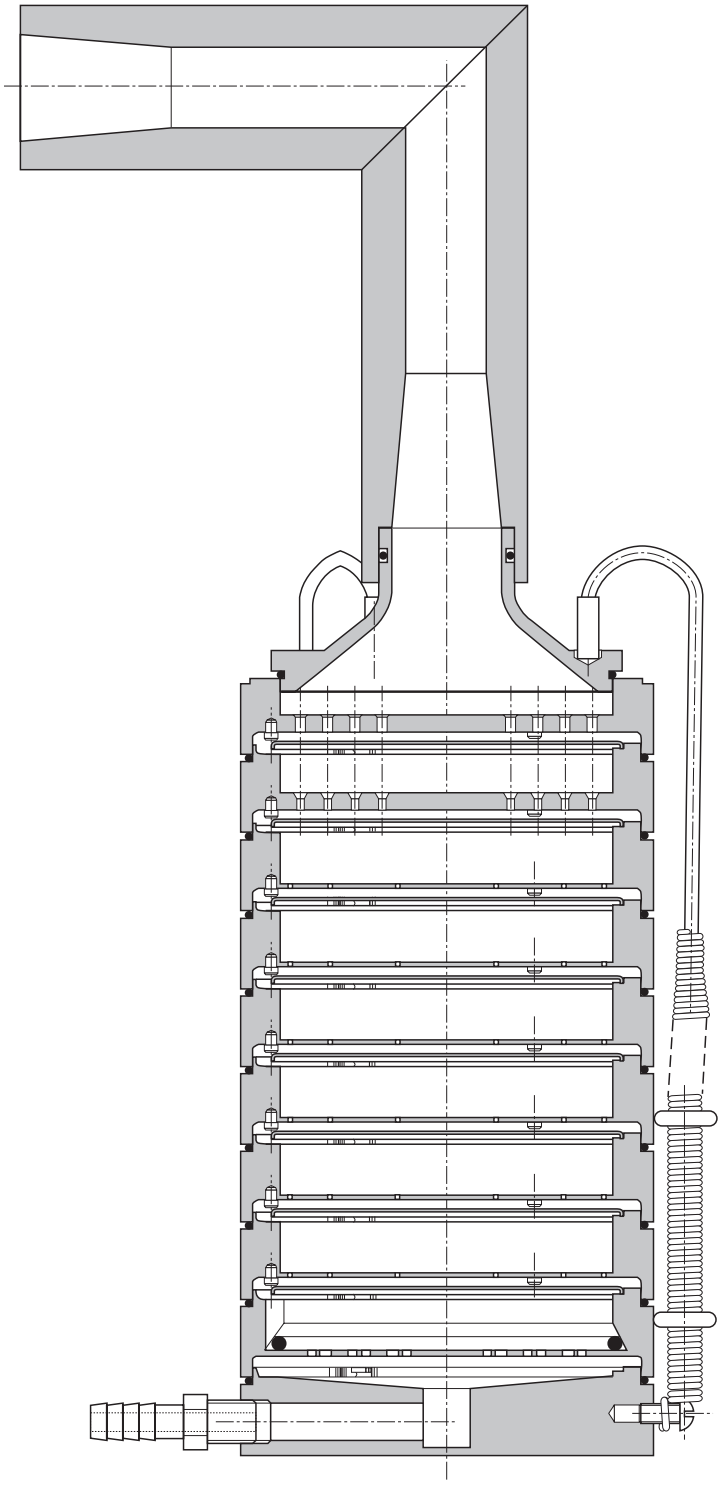

Figure 2.9.18.-9. – *Apparatus D: Andersen cascade impactor used for pressurised inhalers*

the apparatus, as measured at the inlet to the induction port, to 28.3 litres/min (± 5 per cent). Switch off the pump.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge one delivery to waste. Switch on the pump to the apparatus, locate the mouthpiece end of the actuator in the adapter and discharge the inverted inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. Extract the active substance from the inner walls and the collection plate of each of the stages of the apparatus into aliquots of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

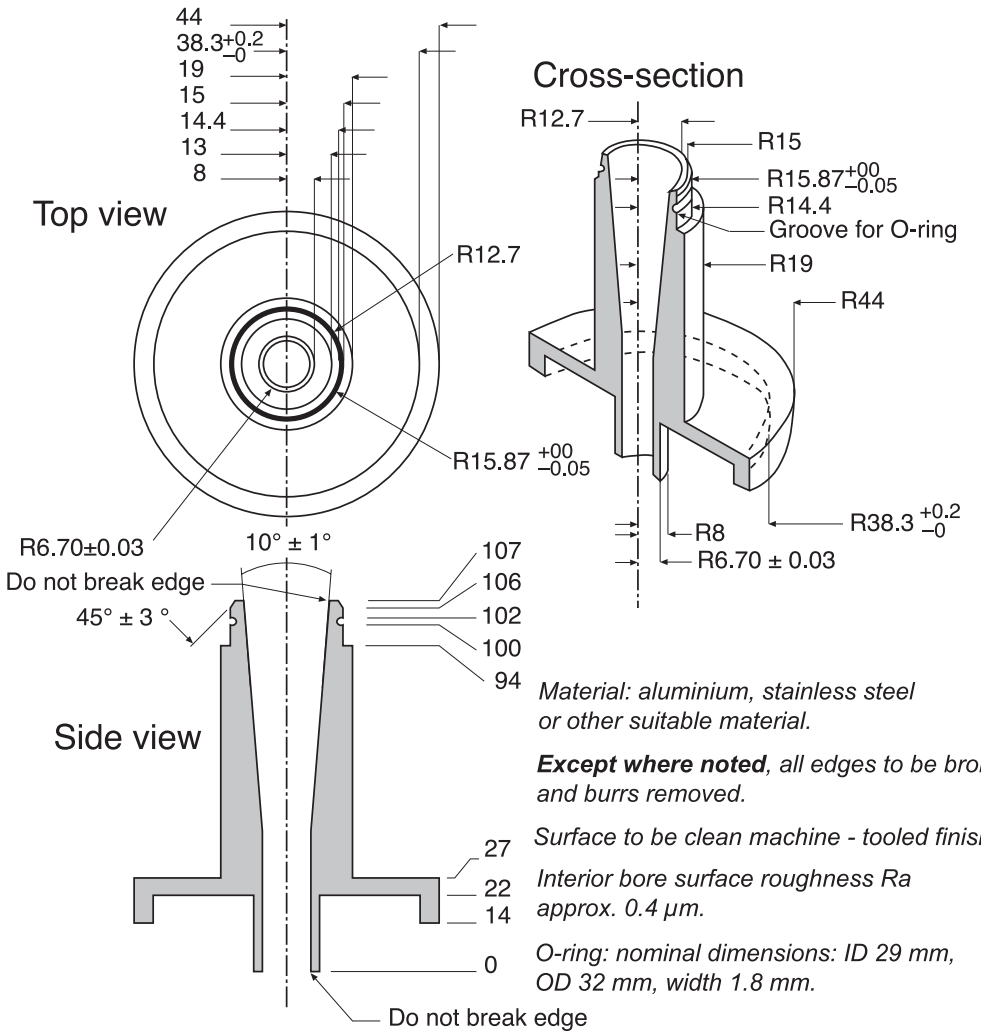

Figure 2.9.18.-10. – *Connection of the induction port to the preseparator of the Andersen cascade impactor*
Dimensions in millimetres unless otherwise stated

Procedure for powder inhalers

The aerodynamic cut-off diameters of the individual stages of this apparatus are currently not well-established at flow rates other than 28.3 litres/min. Users must justify and validate the use of the impactor in the chosen conditions, when flow rates different from 28.3 litres/min are selected.

Assemble the Andersen impactor with the pre-separator and a suitable filter in place and ensure that the system is airtight. Depending on the product characteristics, the pre-separator may be omitted, where justified and authorised. Stages 6 and 7 may also be omitted at high flow rates, if justified. The pre-separator may be coated in the same way as the plates or may contain 10 ml of a suitable solvent. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4.

Unless otherwise defined, conduct the test at the flow rate, Q_{out}, used in the test for uniformity of delivered dose drawing 4 litres of air from the mouthpiece of the inhaler and through the apparatus.

Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter (Q_{out}) using the ideal gas law. For a meter calibrated for the entering volumetric flow (Q_{in}), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

P_0 = atmospheric pressure,

ΔP = pressure drop over the meter.

Adjust the flow control valve to achieve steady flow through the system at the required rate, Q_{out} (± 5 per cent). Ensure that critical flow occurs in the flow control valve by the procedure described for Apparatus C. Switch off the pump.

Prepare the powder inhaler for use according to the patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

Dismantle the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the pre-separator, induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. Extract the active substance from the inner walls and the collection plate of each of the stages of the apparatus into aliquots of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

APPARATUS E

Apparatus E is a cascade impactor with 7 stages and a micro-orifice collector (MOC). Over the flow rate range of 30 litres/min to 100 litres/min the 50 per cent-efficiency cut-off diameters (D_{50} values) range between 0.24 µm to 11.7 µm, evenly spaced on a logarithmic scale. In this flow range, there are always at least 5 stages with D_{50} values between 0.5 µm and 6.5 µm. The collection efficiency curves for each stage are sharp and minimise overlap between stages.

Material of construction may be aluminium, stainless steel or other suitable material.

The impactor configuration has removable impaction cups with all the cups in one plane (Figures 2.9.18.-11/14). There are 3 main sections to the impactor; the bottom frame that holds the impaction cups, the seal body that holds the jets and the lid that contains the interstage passageways (Figures 2.9.18.-11/12). Multiple nozzles are used at all but the first stage (Figure 2.9.18.-13). The flow passes through the impactor in a saw-tooth pattern.

Critical dimensions are provided in Table 2.9.18.-6.

In routine operation, the seal body and lid are held together as a single assembly. The impaction cups are accessible when this assembly is opened at the end of an inhaler test. The cups are held in a support tray, so that all cups can be removed from the impactor simultaneously by lifting out the tray.

An induction port with internal dimensions (relevant to the airflow path) defined in Figure 2.9.18.-7 connects to the impactor inlet. A pre-separator can be added when required, typically with powder inhalers, and connects between the induction port and the impactor. A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port.

Apparatus E contains a terminal Micro-Orifice Collector (MOC) that for most formulations will eliminate the need for a final filter as determined by method validation. The MOC is an impactor plate with nominally 4032 holes, each approximately 70 µm in diameter. Most particles not captured on stage 7 of the impactor will be captured on the cup surface below the MOC. For impactors operated at 60 litres/min, the MOC is capable of collecting 80 per cent of 0.14 µm particles. For formulations with a significant fraction of particles not captured by the MOC, there is an optional filter holder that can replace the MOC or be placed downstream of the MOC (a glass fibre filter is suitable).

Procedure for pressurised inhalers

Place cups into the apertures in the cup tray. Insert the cup tray into the bottom frame, and lower into place. Close the impactor lid with the seal body attached and operate the handle to lock the impactor together so that the system is airtight.

Connect an induction port with internal dimensions defined in Figure 2.9.18.-7 to the impactor inlet. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port. When attached to the mouthpiece adapter, the inhaler is positioned in the same orientation as intended for use. Connect a suitable pump to

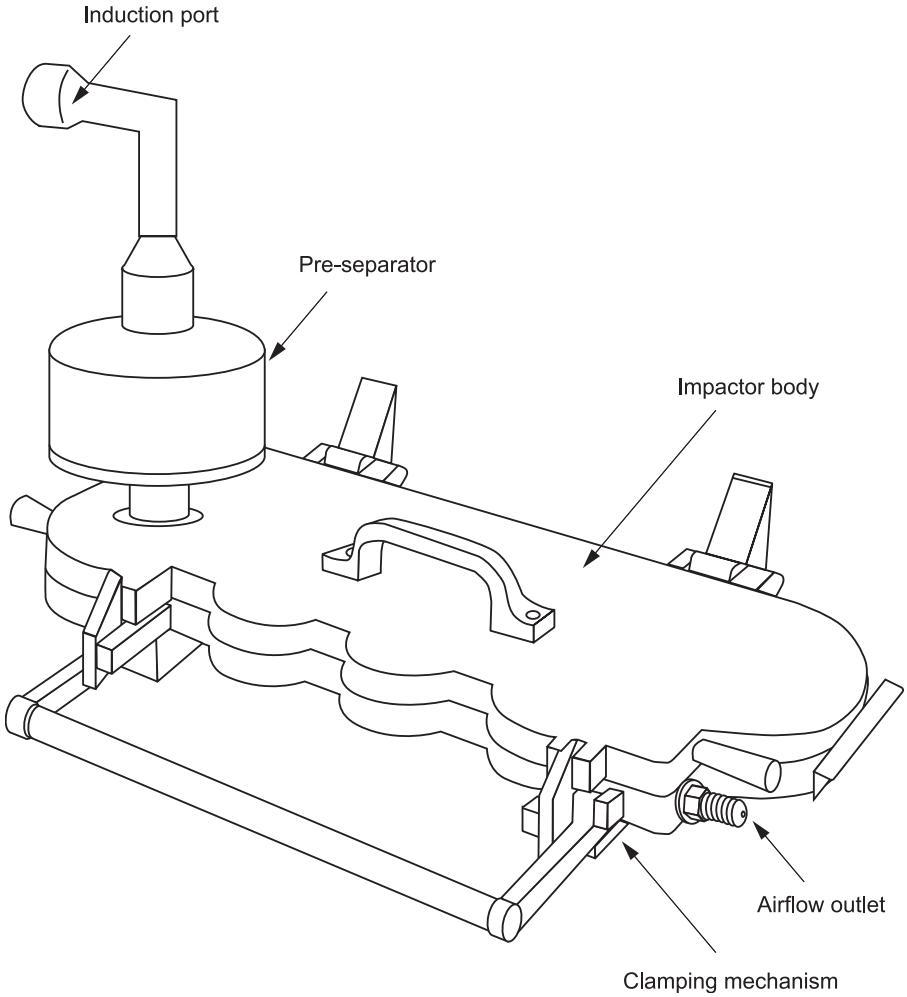

Figure 2.9.18.-11. – *Apparatus E (shown with the pre-separator in place)*

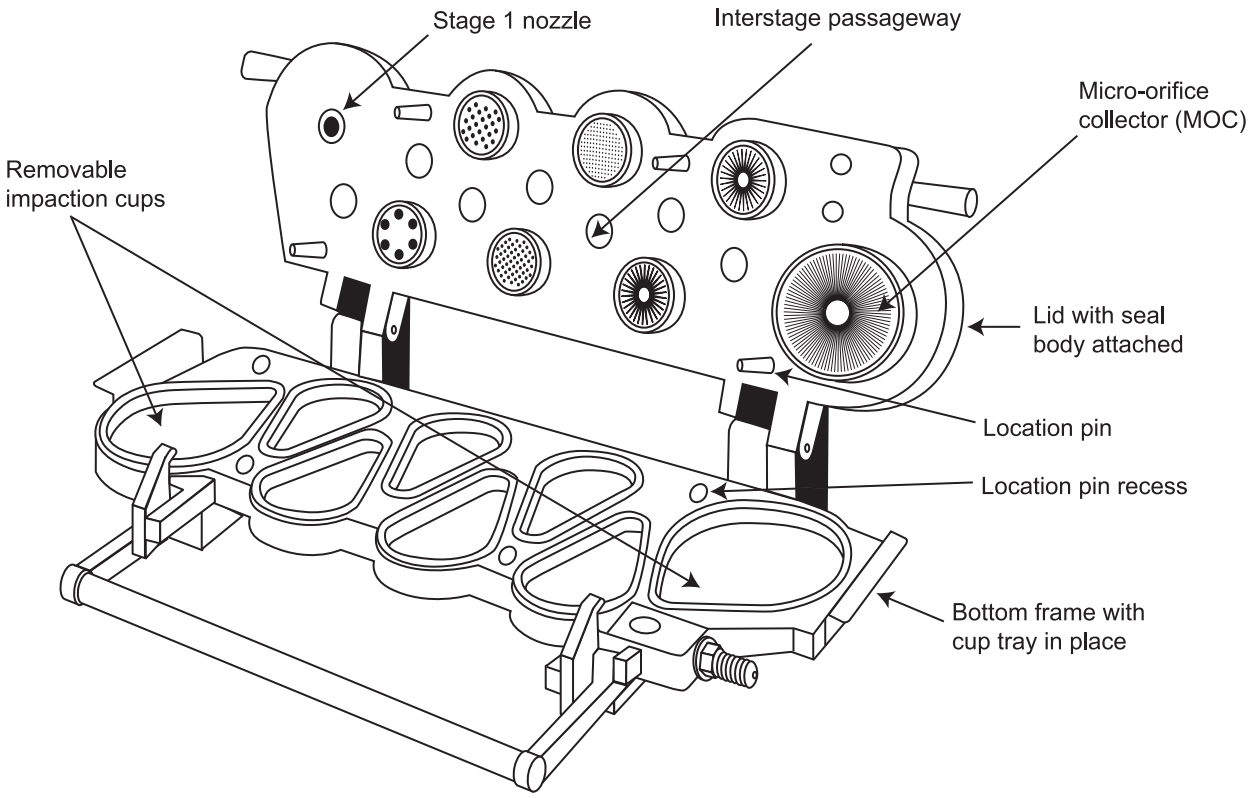

Figure 2.9.18.-12. – *Apparatus E showing component parts*

the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 30 litres/min (± 5 per cent). Switch off the pump.

Table 2.9.18.-6. – *Critical dimensions for apparatus E*

Description	Dimension (mm)
Pre-separator (dimension a - see Figure 2.9.18.-15)	12.8 ± 0.05
Stage 1* Nozzle diameter	14.3 ± 0.05
Stage 2* Nozzle diameter	4.88 ± 0.04
Stage 3* Nozzle diameter	2.185 ± 0.02
Stage 4* Nozzle diameter	1.207 ± 0.01
Stage 5* Nozzle diameter	0.608 ± 0.01
Stage 6* Nozzle diameter	0.323 ± 0.01
Stage 7* Nozzle diameter	0.206 ± 0.01
MOC*	approx. 0.070
Cup depth (dimension b - see Figure 2.9.18.-14)	14.625 ± 0.10
Collection cup surface roughness (Ra)	0.5 - 2 µm
Stage 1 nozzle to seal body distance** - dimension c	0 ± 1.18
Stage 2 nozzle to seal body distance** - dimension c	5.236 ± 0.736
Stage 3 nozzle to seal body distance** - dimension c	8.445 ± 0.410
Stage 4 nozzle to seal body distance** - dimension c	11.379 ± 0.237
Stage 5 nozzle to seal body distance** - dimension c	13.176 ± 0.341
Stage 6 nozzle to seal body distance** - dimension c	13.999 ± 0.071
Stage 7 nozzle to seal body distance** - dimension c	14.000 ± 0.071
MOC nozzle to seal body distance** - dimension c	14.429 to 14.571

* See Figure 2.9.18.-13
** See Figure 2.9.18.-14

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge 1 delivery to waste. Switch on the pump to the apparatus. Prepare the inhaler for use according to the patient instructions, locate the mouthpiece end of the actuator in the adapter and discharge the inhaler into the apparatus, depressing the valve for a sufficient time to ensure a complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised, and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the apparatus and recover the active substance as follows: remove the induction port and mouthpiece adapter from the apparatus and recover the deposited active substance into an aliquot of solvent. Open the impactor by releasing the handle and lifting the lid. Remove the cup tray, with the collection cups, and recover the active substance in each cup into an aliquot of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

Procedure for powder inhalers

Assemble the apparatus with the pre-separator (Figure 2.9.18.-15). Depending on the product characteristics, the pre-separator may be omitted, where justified.

Place cups into the apertures in the cup tray. Insert the cup tray into the bottom frame, and lower into place. Close the impactor lid with the seal body attached and operate the handle to lock the impactor together so that the system is airtight.

When used, the pre-separator should be assembled as follows: assemble the pre-separator insert into the pre-separator base. Fit the pre-separator base to the impactor inlet. Add 15 ml

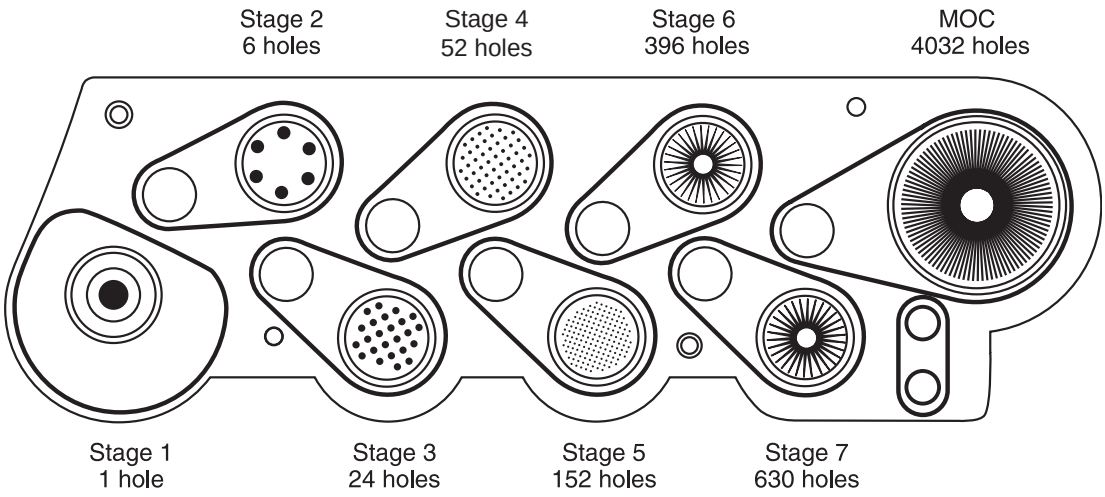

Figure 2.9.18.-13. – *Apparatus E: nozzle configuration*

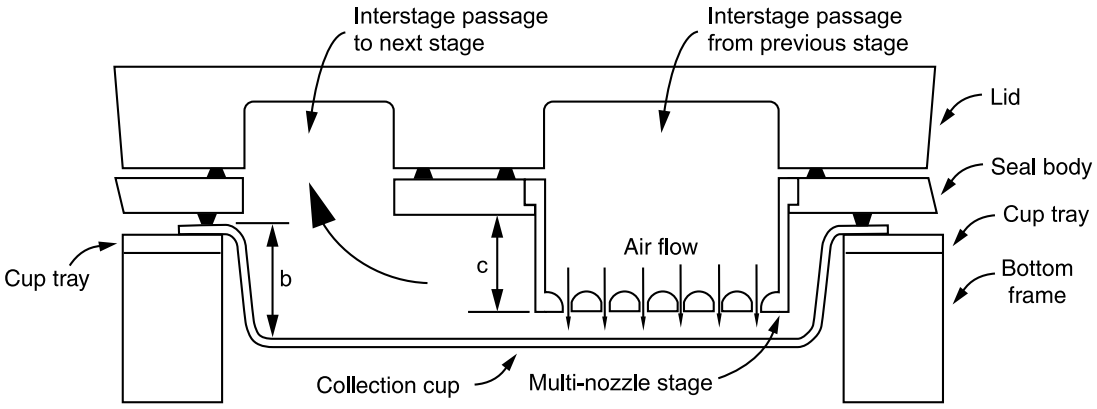

Figure 2.9.18.-14. – *Apparatus E: configuration of interstage passageways*

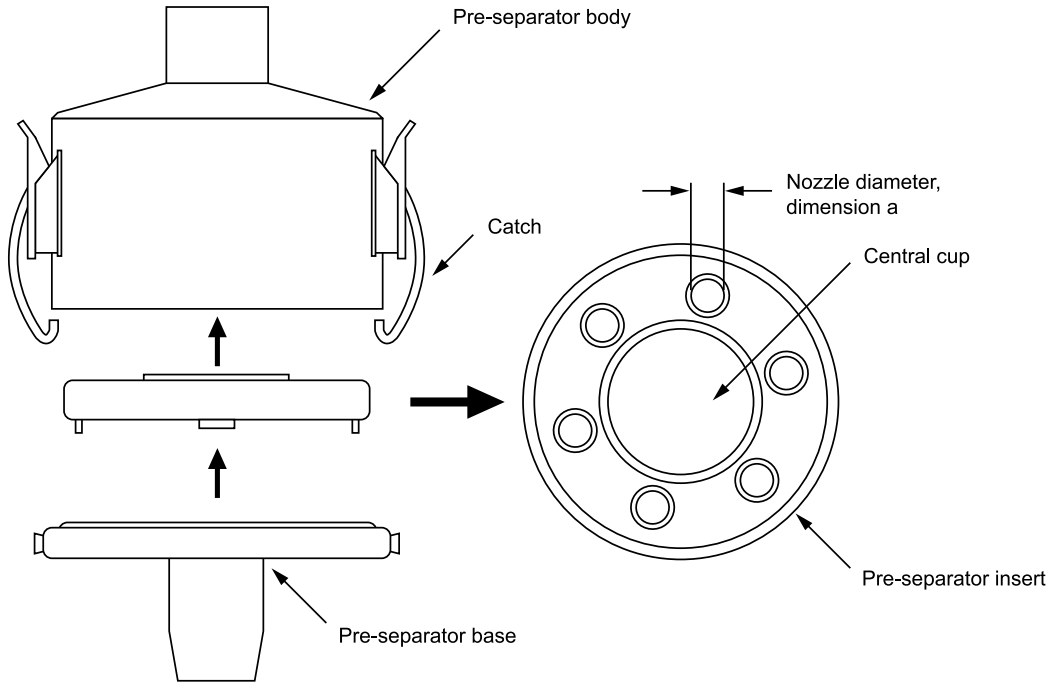

Figure 2.9.18.-15. – *Apparatus E: pre-separator configuration*

of the solvent used for sample recovery to the central cup of the pre-separator insert. Place the pre-separator body on top of this assembly and close the 2 catches.

Connect an induction port with internal dimensions defined in Figure 2.9.18.-7 to the impactor inlet or pre-separator inlet. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the inhaler, when inserted, lines up along the horizontal axis of the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port. When attached to the mouthpiece adapter, the inhaler is positioned in the same orientation as intended for use. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4.

Unless otherwise prescribed, conduct the test at the flow rate, Q_{out}, used in the test for uniformity of delivered dose drawing 4 litres of air from the mouthpiece of the inhaler and through the apparatus. Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter (Q_{out}) using the ideal gas law. For a meter calibrated for the entering volumetric flow (Q_{in}), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

P_0 = atmospheric pressure,

ΔP = pressure drop over the meter.

Adjust the flow control valve to achieve steady flow through the system at the required rate, Q_{out} (± 5 per cent). Ensure that critical flow occurs in the flow control valve by the procedure described for Apparatus C. Switch off the pump.

Prepare the powder inhaler for use according to the patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

Dismantle the apparatus and recover the active substance as follows: remove the induction port and mouthpiece adapter from the pre-separator, when used, and recover the deposited active substance into an aliquot of solvent. When used, remove the pre-separator from the impactor, being careful to avoid spilling the cup liquid into the impactor. Recover the active substance from the pre-separator.

Open the impactor by releasing the handle and lifting the lid. Remove the cup tray, with the collection cups, and recover the active substance in each cup into an aliquot of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

CALCULATIONS

From the analysis of the solutions, calculate the mass of active substance deposited on each stage per discharge and the mass of active substance per discharge deposited in the induction port, mouthpiece adapter and when used, the pre-separator.

Starting at the final collection site (filter or MOC), derive a table of cumulative mass versus cut-off diameter of the respective stage (see Tables 2.9.18.-7 for Apparatus C, 2.9.18.-8 for Apparatus D, 2.9.18.-9 for Apparatus E). Calculate by interpolation the mass of the active substance less than 5 µm. This is the Fine Particle Dose (FPD).

If necessary, and where appropriate (e.g., where there is a log-normal distribution), plot the cumulative fraction of active substance versus cut-off diameter (see Tables 2.9.18.-7/9) on log probability paper, and use this plot to determine values for the Mass Median Aerodynamic Diameter (MMAD) and Geometric Standard Deviation (GSD) as appropriate. Appropriate computational methods may also be used.

Table 2.9.18.-7. – *Calculations for Apparatus C. Use* $q = \sqrt{(60/Q)}$, *where Q is the test flow rate in litres per minute* (Q_{out} *for powder inhalers)*

Cut-off diameter (µm)	Mass of active substance deposited per discharge	Cumulative mass of active substance deposited per discharge	Cumulative fraction of active substance (per cent)
$d_4 = 1.7 \times q$	mass from stage 5, m_5*	$c_4 = m_5$	$f_4 = (c_4/c) \times 100$
$d_3 = 3.1 \times q$	mass from stage 4, m_4	$c_3 = c_4 + m_4$	$f_3 = (c_3/c) \times 100$
$d_2 = 6.8 \times q$	mass from stage 3, m_3	$c_2 = c_3 + m_3$	$f_2 = (c_2/c) \times 100$
	mass from stage 2, m_2	$c = c_2 + m_2$	100

* Stage 5 is the filter stage

Table 2.9.18.-8. – *Calculations for Apparatus D when used at a flow rate of 28.3 litres/min*

Cut-off diameter (µm)	Mass of active substance deposited per discharge	Cumulative mass of active substance deposited per discharge	Cumulative fraction of active substance (per cent)
$d_7 = 0.4$	mass from stage 8, m_8	$c_7 = m_8$	$f_7 = (c_7/c) \times 100$
$d_6 = 0.7$	mass from stage 7, m_7	$c_6 = c_7 + m_7$	$f_6 = (c_6/c) \times 100$
$d_5 = 1.1$	mass from stage 6, m_6	$c_5 = c_6 + m_6$	$f_5 = (c_5/c) \times 100$
$d_4 = 2.1$	mass from stage 5, m_5	$c_4 = c_5 + m_5$	$f_4 = (c_4/c) \times 100$
$d_3 = 3.3$	mass from stage 4, m_4	$c_3 = c_4 + m_4$	$f_3 = (c_3/c) \times 100$

01/2008:20919

2.9.19. PARTICULATE CONTAMINATION: SUB-VISIBLE PARTICLES

Particulate contamination of injections and infusions consists of extraneous, mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions.

For the determination of particulate contamination 2 procedures, Method 1 (Light Obscuration Particle Count Test) and Method 2 (Microscopic Particle Count Test), are specified hereinafter. When examining injections and infusions for sub-visible particles, Method 1 is preferably applied. However, it may be necessary to test some preparations by the light obscuration particle count test followed by the microscopic particle count test to reach a conclusion on conformance to the requirements.

Not all parenteral preparations can be examined for sub-visible particles by one or both of these methods. When Method 1 is not applicable, e.g. in case of preparations having reduced clarity or increased viscosity, the test is carried out according to Method 2. Emulsions, colloids, and liposomal preparations are examples. Similarly, products that produce air or gas bubbles when drawn into the sensor may also require microscopic particle count testing. If the viscosity of the preparation to be tested is sufficiently high so as to preclude its examination by either test method, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

The results obtained in examining a discrete unit or group of units for particulate contamination cannot be extrapolated with certainty to other units that remain untested. Thus, statistically sound sampling plans must be developed if valid inferences are to be drawn from observed data to characterise the level of particulate contamination in a large group of units.

METHOD 1. LIGHT OBSCURATION PARTICLE COUNT TEST

Use a suitable apparatus based on the principle of light blockage which allows an automatic determination of the size of particles and the number of particles according to size.

The apparatus is calibrated using suitable certified reference materials consisting of dispersions of spherical particles of known sizes between 10 µm and 25 µm. These standard particles are dispersed in *particle-free water R*. Care must be taken to avoid aggregation of particles during dispersion.

General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filtration equipment used, except for the membrane filters, with a warm detergent solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse the equipment from top to bottom, outside and then inside, with *particle-free water R*.

Take care not to introduce air bubbles into the preparation to be examined, especially when fractions of the preparation are being transferred to the container in which the determination is to be carried out.

In order to check that the environment is suitable for the test, that the glassware is properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of 5 samples of *particle-free water R*, each of 5 ml, according to the method described below. If the number of particles of 10 µm or greater size exceeds 25 for the combined 25 ml, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware and water are suitable for the test.

Method

Mix the contents of the sample by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water R* and remove the closure, avoiding any contamination of the contents. Eliminate gas bubbles by appropriate measures such as allowing to stand for 2 min or sonicating.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 ml in volume, the contents of 10 or more units are combined in a cleaned container to obtain a volume of not less than 25 ml; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 ml with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable. Small-volume parenterals having a volume of 25 ml or more may be tested individually.

Powders for parenteral use are reconstituted with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 ml or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Remove 4 portions, each of not less than 5 ml, and count the number of particles equal to or greater than 10 µm and 25 µm. Disregard the result obtained for the first portion, and calculate the mean number of particles for the preparation to be examined.

Evaluation

For preparations supplied in containers with a nominal volume of more than 100 ml, apply the criteria of test 1.A.

For preparations supplied in containers with a nominal volume of less than 100 ml, apply the criteria of test 1.B.

For preparations supplied in containers with a nominal volume of 100 ml, apply the criteria of test 1.B

If the average number of particles exceeds the limits, test the preparation by the microscopic particle count test.

Test 1.A — Solutions for infusion or solutions for injection supplied in containers with a nominal content of more than 100 ml

The preparation complies with the test if the average number of particles present in the units tested does not exceed 25 per millilitre equal to or greater than 10 µm and does not exceed 3 per millilitre equal to or greater than 25 µm.

Test 1.B — Solutions for infusion or solutions for injection supplied in containers with a nominal content of less than 100 ml

The preparation complies with the test if the average number of particles present in the units tested does not exceed 6000 per container equal to or greater than 10 µm and does not exceed 600 per container equal to or greater than 25 µm.

METHOD 2. MICROSCOPIC PARTICLE COUNT TEST

Use a suitable binocular microscope, filter assembly for retaining particulate contamination and membrane filter for examination.

The microscope is equipped with an ocular micrometer calibrated with an objective micrometer, a mechanical stage capable of holding and traversing the entire filtration area of the membrane filter, 2 suitable illuminators to provide episcopic illumination in addition to oblique illumination, and is adjusted to 100 ± 10 magnifications.

The ocular micrometer is a circular diameter graticule (see Figure 2.9.19.-1) and consists of a large circle divided by crosshairs into quadrants, transparent and black reference circles 10 µm and 25 µm in diameter at 100 magnifications, and a linear scale graduated in 10 µm increments. It is calibrated using a stage micrometer that is certified by either a domestic or international standard institution. A relative error of the linear scale of the graticule within ± 2 per cent is acceptable. The large circle is designated the graticule field of view (GFOV).

2 illuminators are required. One is an episcopic brightfield illuminator internal to the microscope, the other is an external, focusable auxiliary illuminator adjustable to give reflected oblique illumination at an angle of 10-20°.

The filter assembly for retaining particulate contamination consists of a filter holder made of glass or other suitable material, and is equipped with a vacuum source and a suitable membrane filter.

The membrane filter is of suitable size, black or dark grey in colour, non-gridded or gridded, and 1.0 µm or finer in nominal pore size.

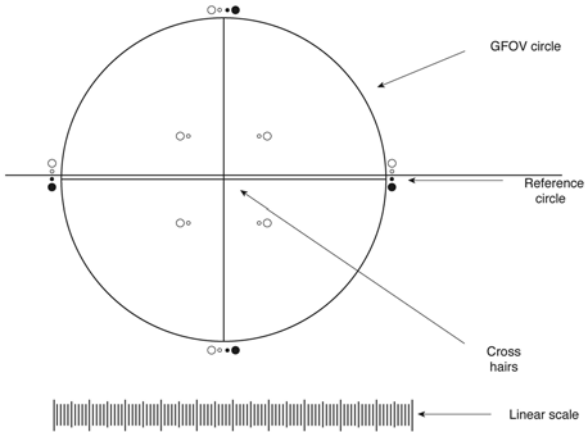

Figure 2.9.19.-1. — *Circular diameter graticule*

General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filter assembly used, except for the membrane filter, with a warm detergent solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse both sides of the membrane filter and the equipment from top to bottom, outside and then inside, with *particle-free water R*.

In order to check that the environment is suitable for the test, that the glassware and the membrane filter are properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of a 50 ml volume of *particle-free water R* according to the method described below. If more than 20 particles 10 µm or larger in size or if more than 5 particles 25 µm or larger in size are present within the filtration area, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, membrane filter and water are suitable for the test.

Method

Mix the contents of the samples by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water R* and remove the closure, avoiding any contamination of the contents.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 ml in volume, the contents of 10 or more units are combined in a cleaned container; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 ml with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable. Small-volume parenterals having a volume of 25 ml or more may be tested individually.

Powders for parenteral use are constituted with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 ml or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Wet the inside of the filter holder fitted with the membrane filter with several millilitres of *particle-free water R*. Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply vacuum. If needed, add stepwise a portion of the solution until the entire volume is filtered. After the last addition of solution, begin rinsing the inner walls of the filter holder by using a jet of *particle-free water R*. Maintain the vacuum until the surface of the membrane filter is free from liquid. Place the filter in a Petri dish and allow the filter to air-dry with the cover slightly ajar. After the filter has been dried, place the Petri dish on the stage of the microscope, scan the entire membrane filter under the reflected light from the illuminating device, and count the number of particles that are equal to or greater than 10 µm and the number of particles that are equal to or greater than 25 µm. Alternatively, partial filter count and determination of the total filter count by calculation is allowed. Calculate the mean number of particles for the preparation to be examined.

The particle sizing process with the use of the circular diameter graticule is carried out by transforming mentally the image of each particle into a circle and then comparing it to the 10 µm and 25 µm graticule reference circles. Thereby the particles are not moved from their initial locations within the graticule field of view and are not superimposed on the reference circles for comparison. The inner diameter of the transparent graticule reference circles is used to size white and transparent particles, while dark particles are sized by using the outer diameter of the black opaque graticule reference circles.

In performing the microscopic particle count test do not attempt to size or enumerate amorphous, semi-liquid, or otherwise morphologically indistinct materials that have the appearance of a stain or discoloration on the membrane filter. These materials show little or no surface relief and present a gelatinous or film-like appearance. In such cases the interpretation of enumeration may be aided by testing a sample of the solution by the light obscuration particle count test.

Evaluation

For preparations supplied in containers with a nominal volume of more than 100 ml, apply the criteria of test 2.A.

For preparations supplied in containers with a nominal volume of less than 100 ml, apply the criteria of test 2.B.

For preparations supplied in containers with a nominal volume of 100 ml, apply the criteria of test 2.B.

Test 2.A — Solutions for infusion or solutions for injection supplied in containers with a nominal content of more than 100 ml

The preparation complies with the test if the average number of particles present in the units tested does not exceed 12 per millilitre equal to or greater than 10 µm and does not exceed 2 per millilitre equal to or greater than 25 µm.

Test 2.B — Solutions for infusion or solutions for injection supplied in containers with a nominal content of less than 100 ml

The preparation complies with the test if the average number of particles present in the units tested does not exceed 3000 per container equal to or greater than 10 µm and does not exceed 300 per container equal to or greater than 25 µm.

2.9.20. PARTICULATE CONTAMINATION: VISIBLE PARTICLES

Particulate contamination of injections and infusions consists of extraneous, mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions.

The test is intended to provide a simple procedure for the visual assessment of the quality of parenteral solutions as regards visible particles. Other validated methods may be used.

APPARATUS

The apparatus (see Figure 2.9.20.-1) consists of a viewing station comprising:

- a matt black panel of appropriate size held in a vertical position,
- a non-glare white panel of appropriate size held in a vertical position next to the black panel,
- an adjustable lampholder fitted with a suitable, shaded, white-light source and with a suitable light diffuser (a viewing illuminator containing two 13 W fluorescent tubes, each 525 mm in length, is suitable). The intensity of illumination at the viewing point is maintained between 2000 lux and 3750 lux, although higher values are preferable for coloured glass and plastic containers.

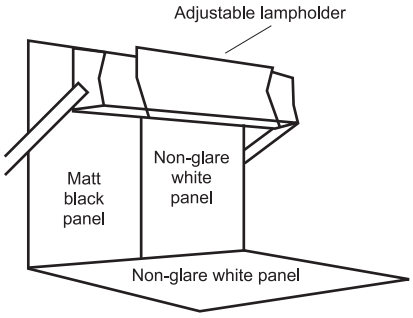

Figure 2.9.20.-1. — *Apparatus for visible particles*

METHOD

Remove any adherent labels from the container and wash and dry the outside. Gently swirl or invert the container, ensuring that air bubbles are not introduced, and observe for about 5 s in front of the white panel. Repeat the procedure in front of the black panel. Record the presence of any particles.

01/2008:20922

2.9.22. SOFTENING TIME DETERMINATION OF LIPOPHILIC SUPPOSITORIES

The test is intended to determine, under defined conditions, the time which elapses until a suppository maintained in water softens to the extent that it no longer offers resistance when a defined weight is applied.

APPARATUS A

The apparatus (see Figure 2.9.22.-1) consists of a glass tube 15.5 mm in internal diameter with a flat bottom and a length of about 140 mm. The tube is closed by a removable plastic cover having an opening 5.2 mm in diameter. The apparatus comprises a rod 5.0 mm in diameter which becomes wider

towards the lower end, reaching a diameter of 12 mm. A metal needle 2 mm in length and 1 mm in diameter is fixed on the flat underside.

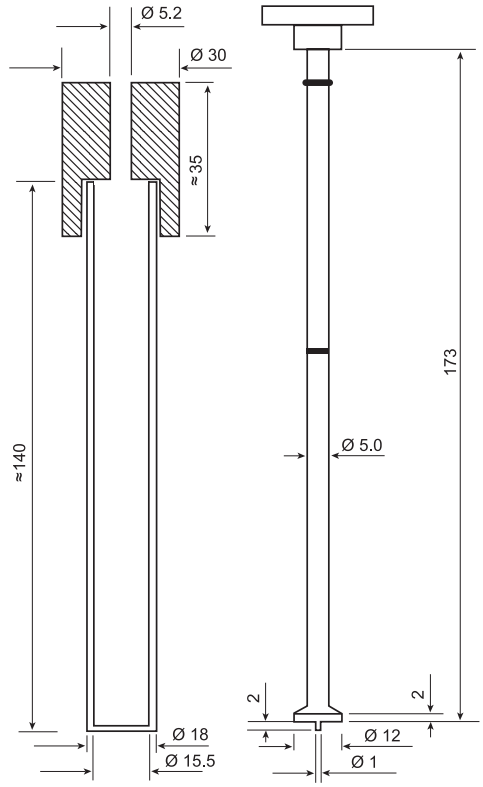

Figure 2.9.22.-1. – *Apparatus A for measuring the softening time of lipophilic suppositories*
Dimensions in millimetres

The rod consists of 2 parts, a lower part made of plastic material and an upper part made of plastic material or metal with a weight disk. The upper and lower parts are either fitted together (manual version) or separate (automated version). The weight of the entire rod is 30 ± 0.4 g. The upper part of the rod carries a sliding mark ring. When the rod is introduced into the glass tube so that it touches the bottom, the mark ring is adjusted to coincide with the upper level of the plastic cover.

Method. Place the glass tube containing 10 ml of water in a water-bath and equilibrate at 36.5 ± 0.5 °C. Fix the glass tube vertically and immerse to a depth of at least 7 cm below the surface but without touching the bottom of the water-bath. Introduce a suppository, tip first, into the tube followed by the rod with the free gliding plastic cover into the glass tube until the metal needle touches the flat end of the suppository. Put the cover on the tube (beginning of time measurement). Note the time which elapses until the rod sinks down to the bottom of the glass tube and the mark ring reaches the upper level of the plastic cover.

APPARATUS B

The apparatus (see Figure 2.9.22.-2) consists of a water-bath (B) into which an inner tube (A) is inserted and fixed with a stopper. The inner tube is closed by a stopper at the bottom. The apparatus is fitted with a thermometer. 2 insets are available:

– a glass rod (C1) in the form of a tube sealed at both ends, carrying a rim at its lower end weighed with lead shot, which has a weight of 30 ± 0.4 g,
– a penetration inset (C2) consisting of a rod (7.5 ± 0.1 g) in a tube which has an enlargement for the suppository, both made of stainless steel.

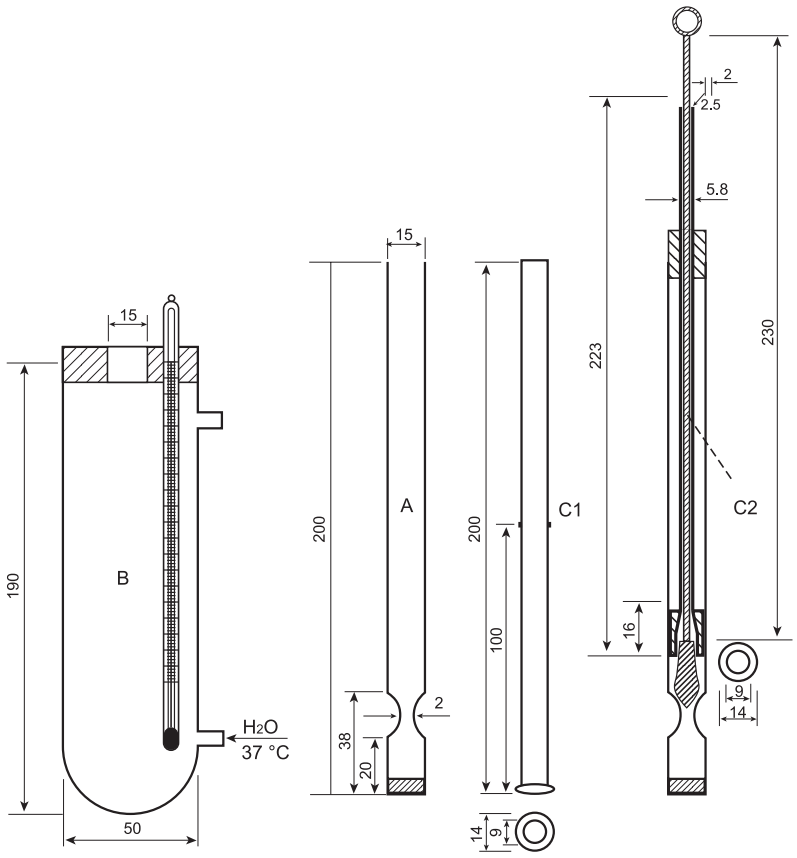

Figure 2.9.22.-2. – *Apparatus B for measuring the softening time of lipophilic suppositories*
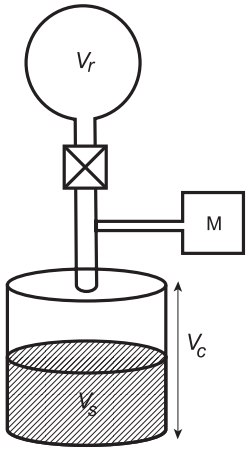
Dimensions in millimetres

Method. Pour 5 ml of water at 36.5 ± 0.5 °C into the inner tube (A), introduce a suppository with the tip downwards and onto that, place the inset (C1 or C2). Note the time which elapses between this moment and the moment when the lower, rimmed end of the glass rod (C1) or the steel rod (C2) reaches the narrowed part of the inner glass tube. Melting or dissolution is then considered as complete.

01/2008:20923



2.9.23. PYCNOMETRIC DENSITY OF SOLIDS

The test for pycnometric density of solids is intended to determine the volume occupied by a known mass of powder by measuring the volume of gas displaced under defined conditions. Hence, its pycnometric density is calculated.

APPARATUS

The apparatus (see Figure 2.9.23.-1) consists of the following:

- a sealed test cell, with an empty cell volume (V_c), connected through a valve to a reference cell, with a reference volume (V_r),
- a system capable of pressurising the test cell with the measurement gas until a defined pressure (P) indicated by a manometer,
- the system is connected to a source of measurement gas, which is preferably helium, unless another gas is specified(5).

V_r = reference volume

V_c = cell volume

V_s = sample volume

M = manometer

Figure 2.9.23.-1. – *Schematic diagram of a gas pycnometer*

The temperature of the gas pycnometer is between 15 °C and 30 °C and must not vary by more than 2 °C during the course of measurement.

The apparatus is calibrated which means that the volumes (V_c) and (V_r) are determined, using calibrated, polished steel balls having a total volume (around 6 cm^3) known to the nearest 0.001 cm^3. The procedure described below is followed in two runs. Firstly, with an empty test cell and secondly with the steel balls placed in the test cell. The volumes (V_c) and (V_r) are calculated using the equation for the sample volume taking into account that the volume is zero in the first run.

METHOD

Weigh the test cell of the pycnometer and record the mass. Fill the test cell with a given mass of powder of the substance to be examined. Seal the test cell in the pycnometer. Remove volatile contaminants in the powder by degassing the powder under a constant purge of gas; occasionally, powders may initially have to be degassed under vacuum. Record the system reference pressure (P_r) as indicated by the manometer while the valve that connects the reference cell with the test cell is open. Close the valve to separate the reference cell from the test cell. Pressurise the test cell with the gas to an initial pressure (P_i) and record the value obtained. Open the valve to connect the reference cell with the test cell. Record the final pressure (P_f). Repeat the measurement sequence for the same powder sample until consecutive measurements of the sample volume (V_s) agree to within 0.5 per cent. The sample volume is expressed in cubic centimetres. Unload the test cell and measure the final powder mass (m) expressed in grams.

EXPRESSION OF THE RESULTS

The sample volume (V_s) is given by the expression:

$$V_s = V_c - \frac{V_r}{\frac{P_i - P_r}{P_f - P_r} - 1}$$

The density (ρ) is given by the equation:

$$\rho = \frac{m}{V_s}$$

01/2008:20925

2.9.25. DISSOLUTION TEST FOR MEDICATED CHEWING GUMS

PRINCIPLE

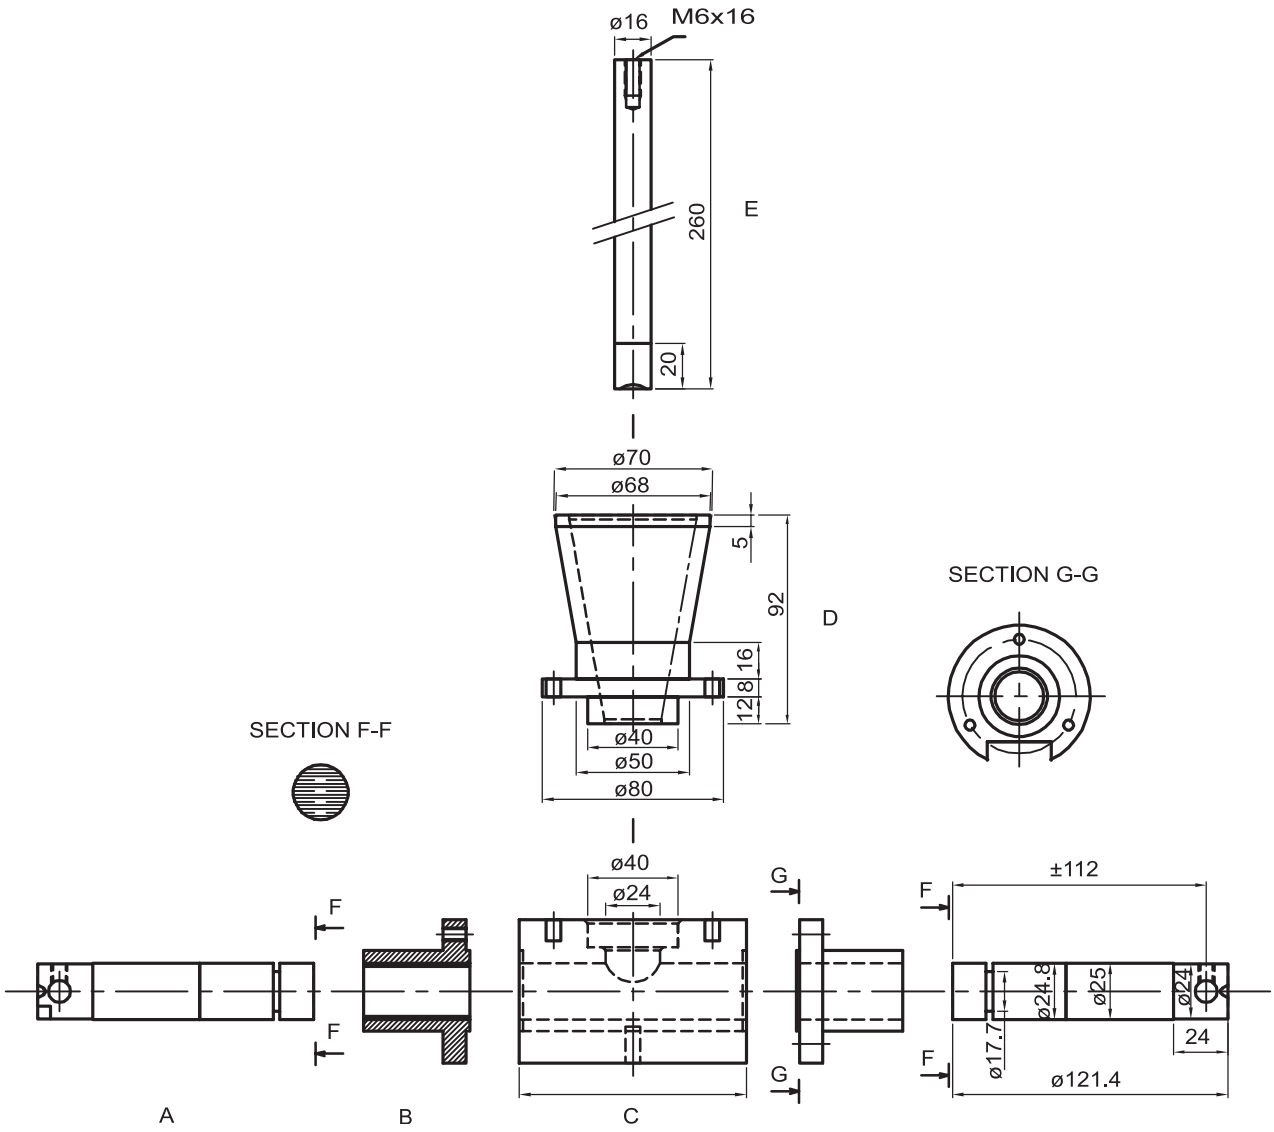
The test is used to determine the dissolution rate of active substances in medicated chewing gums. This is done by applying a mechanical kneading procedure to a piece of gum placed in a small chamber designed to simulate the process of chewing.

APPARATUS

The chewing apparatus (Figure 2.9.25.-1) consists of:

- 1 chewing chamber,
- 1 vertical piston,
- 2 horizontal pistons with O-rings and sealing rings.

The chewing chamber consists of 4 individual parts:



- 1 central chamber,
- 1 funnel (Figure 2.9.25.-2),
- 2 guides with bushes (Figure 2.9.25.-3).

Funnel and guides are mounted on the central chamber. The O-rings are incorporated in the piston recess with the sealing ring round it; the sealing rings ensure that the chamber is watertight. The horizontal pistons are placed in the chewing chamber through the guides.

The gum is artificially chewed by the horizontal pistons, and the vertical piston ensures that the gum stays in the right place between chews.

Machine speed is controlled to ensure a constant cycle. One cycle (chew) is defined as follows: the horizontal pistons start from their outermost position, move to their innermost

(5) If gases other than helium are used, it would not be surprising to obtain values different from those obtained with helium, since the penetration of the gas is dependent on the size of the pore as well as the cross-sectional area of the penetrating molecule. For example, the pycnometric density of porous materials will be overestimated by a measure using nitrogen by comparison with helium.

A. Horizontal piston
B. Guide
C. Chewing chamber
D. Funnel
E. Vertical piston

Figure 2.9.25.-1 – *Chewing chamber and pistons*
(dimensions in millimetres)

position and back to their outermost position. Within one cycle, the vertical piston moves from its lowest position to its uppermost position and back to its lowest position.

Each horizontal piston has a stroke of 25.0 mm. The maximum distance between these 2 pistons is 50 mm. The minimum distance between the 2 horizontal pistons is 0.1 mm to 1.0 mm. The vertical piston has a stroke of 22.0 mm.

Horizontal piston movement is controlled, so that the 2 pistons are at their innermost position at the same time. Vertical piston movement is controlled, so it does not conflict with the movement of the horizontal pistons.

If necessary, the machine can be constructed so that the horizontal pistons rotate around their own axes in opposite direction to each other by the end of the chew in order to obtain maximum chewing.

All parts of the apparatus that may come in contact with the preparation or the dissolution medium are chemically inert and do not adsorb, react or interfere with the sample.

PROCEDURE

For each determination, the following information is needed:

- composition, volume and temperature of the dissolution medium,
- number of chews per minute,
- time and sampling method,
- whether the analysis is performed on the gum residue or on the dissolution medium,
- method of analysis.

Place the prescribed volume of dissolution medium in the chewing chamber, usually 20 ml of *phosphate buffer solution pH 6.0 R2*. Maintain the medium temperature at 37 ± 0.5 °C using an electrical device with external control. Set the piston speed at the prescribed number of chews per minute (usually 60). Accurately weigh a portion of gum or the whole gum, put it into the chewing chamber and start the machine.

SAMPLING AND EVALUATION

Stop the apparatus at the prescribed time. Remove the gum residue and take a sample of the dissolution medium. Determine the content of active substance(s) by a suitable method. Medium replacement may be made after each sampling procedure; compensation by calculation of medium

volume change or sample dilution is needed. Alternatively, determine the content of active substance(s) remaining in the gum residue. Carry out the test successively on 6 medicated chewing gums.

The quantity of active substance(s) dissolved in a specified time is expressed as a percentage of the content stated on the label.

2.9.26. SPECIFIC SURFACE AREA BY GAS ADSORPTION

INTRODUCTION

The specific surface area of a powder is determined by physical adsorption of a gas on the surface of the solid and by calculating the amount of adsorbate gas corresponding to a monomolecular layer on the surface. Physical adsorption results from relatively weak forces (van der Waals forces) between the adsorbate gas molecules and the adsorbent surface of the test powder. The determination is usually carried out at the temperature of liquid nitrogen. The amount of gas adsorbed can be measured by a volumetric or continuous flow procedure.

BRUNAUER, EMMETT AND TELLER (BET) THEORY AND SPECIFIC SURFACE AREA DETERMINATION

MULTI-POINT MEASUREMENT

The data are treated according to the Brunauer, Emmett and Teller (BET) adsorption isotherm equation:

$$\frac{1}{\left[V_a\left(\frac{P_o}{P}-1\right)\right]} = \frac{C-1}{V_m C} \times \frac{P}{P_o} + \frac{1}{V_m C} \qquad (1)$$

P = partial vapour pressure of adsorbate gas in equilibrium with the surface at 77.4 K (b.p. of liquid nitrogen), in pascals,

P_o = saturated pressure of adsorbate gas, in pascals,

V_a = volume of gas adsorbed at standard temperature and pressure (STP) [273.15 K and atmospheric pressure (1.013×10^5 Pa)], in millilitres,

V_m = volume of gas adsorbed at STP to produce an apparent monolayer on the sample surface, in millilitres,

C = dimensionless constant that is related to the enthalpy of adsorption of the adsorbate gas on the powder sample.

A value of V_a is measured at each of not less than 3 values of P/P_o.

Then the BET value

$$\frac{1}{\left[V_a\left(\frac{P_o}{P}-1\right)\right]}$$

is plotted against P/P_o according to equation (1). This plot should yield a straight line usually in the approximate relative pressure range 0.05 to 0.3. The data are considered acceptable if the correlation coefficient, r, of the linear regression is not less than 0.9975; that is, r^2 is not less than 0.995. From the resulting linear plot, the slope, which is equal to $(C-1)/V_mC$, and the intercept, which is equal to $1/V_mC$, are evaluated by linear regression analysis. From these values, V_m is calculated as $1/(slope + intercept)$, while C is calculated as $(slope/intercept) + 1$. From the value of V_m so determined, the specific surface area, S, in $m^2 \cdot g^{-1}$, is calculated by the equation:

$$S = \frac{V_m N a}{m \times 22400} \qquad (2)$$

N = Avogadro constant (6.022×10^{23} mol^{-1}),

a = effective cross-sectional area of one adsorbate molecule, in square metres (0.162 nm^2 for nitrogen and 0.195 nm^2 for krypton),

m = mass of test powder, in grams,

22400 = volume occupied by 1 mole of the adsorbate gas at STP allowing for minor departures from the ideal, in millilitres.

A minimum of 3 data points is required. Additional measurements may be carried out, especially when non-linearity is obtained at a P/P_o value close to 0.3.

Because non-linearity is often obtained at a P/P_o value below 0.05, values in this region are not recommended. The test for linearity, the treatment of the data, and the calculation of the specific surface area of the sample are described above.

SINGLE-POINT MEASUREMENT

Normally, at least 3 measurements of V_a each at different values of P/P_o are required for the determination of specific surface area by the dynamic flow gas adsorption technique (*Method I*) or by volumetric gas adsorption (*Method II*). However, under certain circumstances described below, it may be acceptable to determine the specific surface area of a powder from a single value of V_a measured at a single value of P/P_o such as 0.300 (corresponding to 0.300 mole of nitrogen or 0.001038 mole fraction of krypton), using the following equation for calculating V_m:

$$V_m = V_a \left(1 - \frac{P}{P_o}\right) \qquad (3)$$

The specific surface area is then calculated from the value of V_m by equation (2) given above.

The single-point method may be employed directly for a series of powder samples of a given material for which the material constant C is much greater than unity. These circumstances may be verified by comparing values of specific surface area determined by the single-point method with that determined by the multiple-point method for the series of powder samples. Close similarity between the single-point values and multiple-point values suggests that $1/C$ approaches zero.

The single-point method may be employed indirectly for a series of very similar powder samples of a given material for which the material constant C is not infinite but may be assumed to be invariant. Under these circumstances, the error associated with the single-point method can be reduced or eliminated by using the multiple-point method to evaluate C for one of the samples of the series from the BET plot, from which C is calculated as (1 + *slope/intercept*). Then V_m is calculated from the single value of V_a measured at a single value of P/P_o by the equation:

$$V_m = V_a \left(\frac{P_o}{P} - 1\right) \left[\frac{1}{C} + \frac{C-1}{C} \times \left(\frac{P}{P_o}\right)\right] \qquad (4)$$

The specific surface area is calculated from V_m by equation (2) given above.

EXPERIMENTAL TECHNIQUES

This section describes the methods to be used for the sample preparation, the dynamic flow gas adsorption technique (*Method I*) and the volumetric gas adsorption technique (*Method II*).

SAMPLE PREPARATION

Outgassing

Before the specific surface area of the sample can be determined, it is necessary to remove gases and vapours that may have become physically adsorbed onto the surface after manufacture and during treatment, handling and storage. If outgassing is not achieved, the specific surface area may be reduced or may be variable because an intermediate area of the surface is covered with molecules of the previously adsorbed gases or vapours. The outgassing conditions are critical for obtaining the required precision and accuracy of specific surface area measurements on pharmaceuticals because of the sensitivity of the surface of the materials.

Conditions. The outgassing conditions must be demonstrated to yield reproducible BET plots, a constant weight of test powder, and no detectable physical or chemical changes in the test powder.

The outgassing conditions defined by the temperature, pressure and time should be chosen so that the original surface of the solid is reproduced as closely as possible. Outgassing of many substances is often achieved by applying a vacuum, by purging the sample in a flowing stream of a non-reactive, dry gas, or by applying a desorption-adsorption cycling method. In either case, elevated temperatures are sometimes applied to increase the rate at which the contaminants leave the surface. Caution should be exercised when outgassing powder samples using elevated temperatures to avoid affecting the nature of the surface and the integrity of the sample.

If heating is employed, the recommended temperature and time of outgassing are as low as possible to achieve reproducible measurement of specific surface area in an acceptable time. For outgassing sensitive samples, other outgassing methods such as the desorption-adsorption cycling method may be employed.

Adsorbate

The standard technique is the adsorption of nitrogen of analytical quality at liquid nitrogen temperature.

For powders of low specific surface area (< 0.2 $m^2 \cdot g^{-1}$) the proportion adsorbed is low. In such cases the use of krypton at liquid nitrogen temperature is preferred because the low vapour pressure exerted by this gas greatly reduces error. The use of larger sample quantities where feasible (equivalent to 1 m^2 or greater total surface area using nitrogen) may compensate for the errors in determining low surface areas.

All gases used must be free from moisture.

Quantity of sample

Accurately weigh a quantity of the test powder such that the total surface of the sample is at least 1 m^2 when the adsorbate is nitrogen and 0.5 m^2 when the adsorbate is krypton.

Lower quantities of sample may be used after appropriate validation.

MEASUREMENTS

Because the amount of gas adsorbed under a given pressure tends to increase on decreasing the temperature, adsorption measurements are usually made at a low temperature. Measurement is performed at 77.4 K, the boiling point of liquid nitrogen.

Method I: the dynamic flow method

Principle

In the dynamic flow method (see Figure 2.9.26.-1), the recommended adsorbate gas is dry nitrogen or krypton, while helium is employed as a diluent gas, which is not adsorbed under the recommended conditions.

A minimum of 3 mixtures of the appropriate adsorbate gas with helium are required within the P/P_o range 0.05 to 0.30.

The gas detector-integrator should provide a signal that is approximately proportional to the volume of the gas passing through it under defined conditions of temperature and pressure. For this purpose, a thermal conductivity detector with an electronic integrator is one among various suitable types. A minimum of 3 data points within the recommended range of 0.05 to 0.30 for P/P_o is to be determined.

Procedure

A known mixture of the gases, usually nitrogen and helium, is passed through a thermal conductivity cell, through the sample, again through the thermal conductivity cell and then to a recording potentiometer.

Immerse the sample cell in liquid nitrogen, then the sample adsorbs nitrogen from the mobile phase. This unbalances the thermal conductivity cell, and a pulse is generated on a recorder chart.

Remove from the coolant; this gives a desorption peak equal in area and in the opposite direction to the adsorption peak. Since this is better defined than the adsorption peak, it is the one used for the determination.

To effect the calibration, inject a known quantity of adsorbate into the system, sufficient to give a peak of similar magnitude to the desorption peak and obtain the proportion of gas volume per unit peak area.

Use a nitrogen/helium mixture for a single-point determination and several such mixtures or premixing 2 streams of gas for a multiple-point determination.

Calculation is essentially the same as for the volumetric method.

Method II: the volumetric method

Principle

In the volumetric method (see Figure 2.9.26.-2), the recommended adsorbate gas is nitrogen which is admitted into the evacuated space above the previously outgassed powder sample to give a defined equilibrium pressure, P, of the gas. The use of a diluent gas, such as helium, is therefore unnecessary, although helium may be employed for other purposes, such as to measure the dead volume.

Since only pure adsorbate gas, instead of a gas mixture, is employed, interfering effects of thermal diffusion are avoided in this method.

Procedure

Admit a small amount of dry nitrogen into the sample tube to prevent contamination of the clean surface, remove the sample tube, insert the stopper, and weigh it. Calculate the weight of the sample. Attach the sample tube to the volumetric apparatus. Cautiously evacuate the sample down to the specified pressure (e.g. between 2 Pa and 10 Pa). Alternatively, some instruments operate by evacuating to a defined rate of pressure change (e.g. less than 13 Pa/30 s) and holding for a defined period of time before commencing the next step.

If the principle of operation of the instrument requires the determination of the dead volume in the sample tube, for example, by the admission of a non-adsorbed gas, such as helium, this procedure is carried out at this point, followed by evacuation of the sample. The determination of dead volume may be avoided using difference measurements, that is, by means of reference and sample tubes connected by a differential transducer. The adsorption of nitrogen gas is then measured as described below.

Raise a Dewar vessel containing liquid nitrogen at 77.4 K up to a defined point on the sample cell. Admit a sufficient volume of adsorbate gas to give the lowest desired relative pressure. Measure the volume adsorbed, V_a. For multipoint measurements, repeat the measurement of V_a at successively higher P/P_o values. When nitrogen is used as the adsorbate gas, P/P_o values of 0.10, 0.20, and 0.30 are often suitable.

REFERENCE MATERIALS

Periodically verify the functioning of the apparatus using appropriate reference materials of known surface area, such as α-alumina, which should have a specific surface area similar to that of the sample to be examined.

2.9.27. UNIFORMITY OF MASS OF DELIVERED DOSES FROM MULTIDOSE CONTAINERS

The following test is intended for oral dosage forms such as granules, powders for oral use and liquids for oral use, which are supplied in multidose containers provided at manufacture with a measuring device.

Weigh individually 20 doses taken at random from one or more containers with the measuring device provided and determine the individual and average masses. Not more than 2 of the individual masses deviate from the average mass by more than 10 per cent and none deviates by more than 20 per cent.

01/2008:20929

2.9.29. INTRINSIC DISSOLUTION

The test is intended to determine the intrinsic dissolution rate of pure solid substances following compaction. It is carried out under specified experimental conditions such that a practical measure of the intrinsic dissolution rate is obtained.

The intrinsic dissolution rate is a theoretical value referring to pure solid substances having null porosity, but, practically, intrinsic dissolution rate is determined on substances having a minimal porosity.

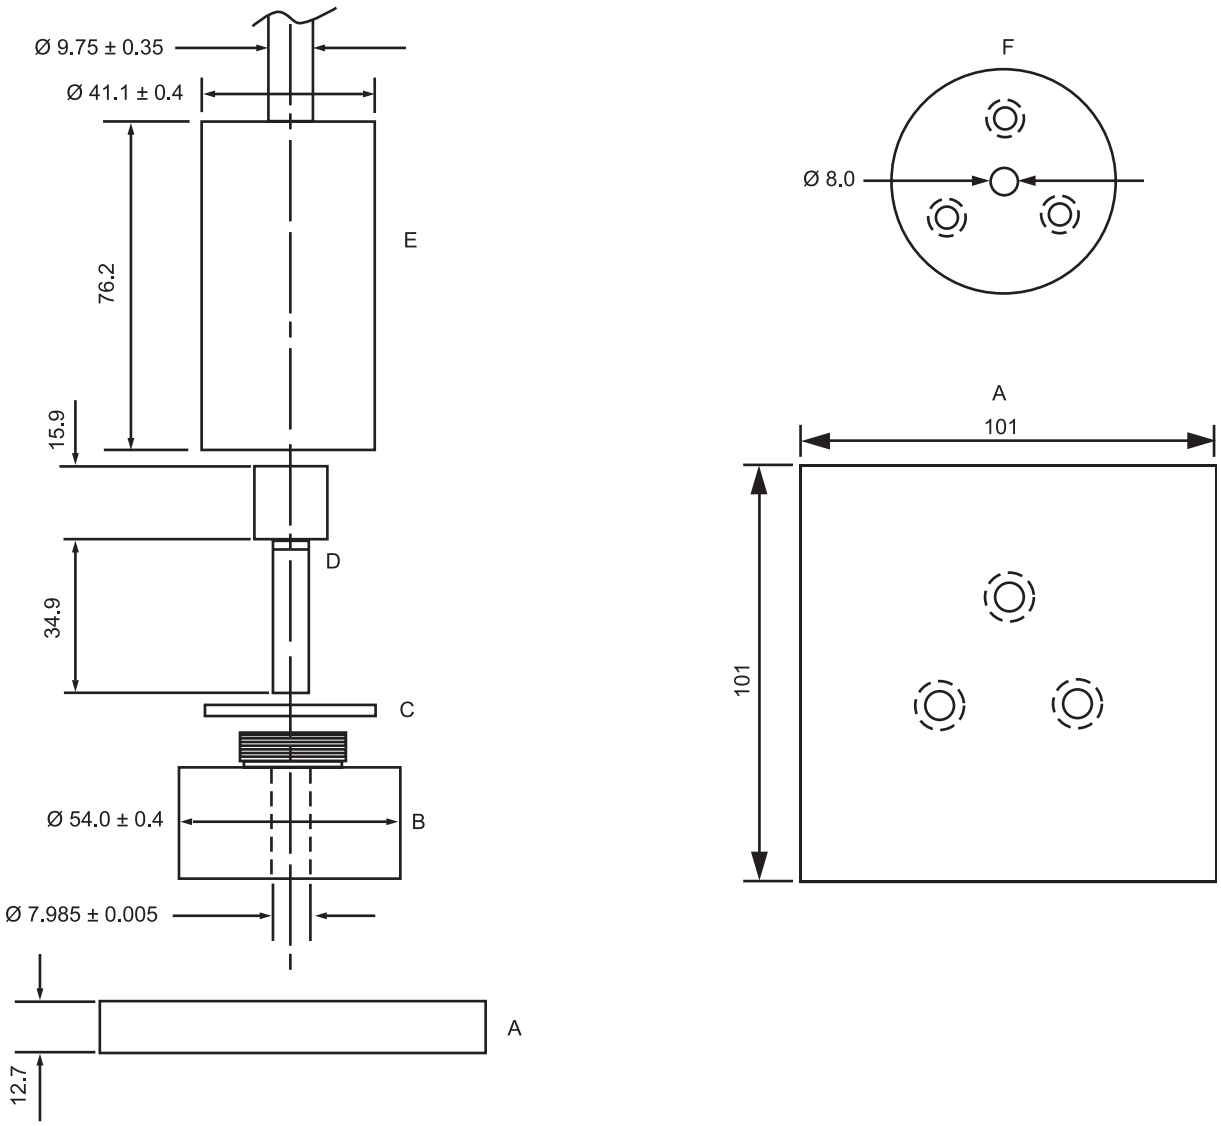
PRINCIPLE

The intrinsic dissolution rate is defined as the dissolution rate of pure substances following compaction under the condition of constant surface area. Its assessment is useful in the characterisation of active substances and excipients.

The dissolution rate of pure substances can be affected by all the solid state properties such as crystal habit, crystallinity, amorphism, polymorphism, pseudo-polymorphism, particle size and specific surface area. In addition, it can also be influenced by extrinsic factors (test conditions), such as hydrodynamics, temperature, viscosity, pH, buffer strength and ionic strength of the dissolution medium.

The assessment of intrinsic dissolution rate of a solid substance involves the preparation of a compact. Assurance of appropriate compaction properties of the powder to be tested is needed prior to performing the test.

The intrinsic dissolution rate is determined by exposing a constant area of the compacted substance to an appropriate dissolution medium, while maintaining constant stirring rate, temperature, ionic strength and pH.



The intrinsic dissolution rate is expressed in terms of dissolved mass of substance per time per exposed area, typically in milligrams per minute per square centimetre ($mg \cdot min^{-1} \cdot cm^{-2}$).

APPARATUS

A typical apparatus consists of a punch and die fabricated out of hardened steel. The base of the die has 3 threaded holes for the attachment of a surface plate made of polished steel, providing a mirror-smooth base for the compact. The die has a 0.1-1.0 cm diameter cavity into which a measured amount of the powder to be tested is placed. The punch is then inserted in the die cavity and the material is compressed, generally using a benchtop hydraulic press. A hole through the head of the punch allows insertion of a metal rod to facilitate removal from the die after the test. A compact is formed in the cavity with a single face of defined area exposed on the bottom of the die (Figure 2.9.29.-1). The bottom of the die cavity is threaded so that at least 50-75 per cent of the compact can dissolve without falling out of the die. The top of the die has a threaded shoulder that allows it to be attached to a holder. The holder is mounted on a laboratory stirring device, and the entire die, with the compact still in place, is immersed in the dissolution medium and rotated by the stirring device.

PROCEDURE

Weigh the material onto a piece of weighing paper. Attach the surface plate to the underside of the die, and secure it with the 3 provided screws. Transfer the sample of powder tested into the die cavity. Place the punch into the chamber,

A. Surface plate
B. Die
C. Neoprene gasket
D. Punch
E. Holder and shaft assembly
F. Die underside

Figure 2.9.29.-1. – *Typical apparatus used to obtain the compact for the determination of the intrinsic dissolution Dimensions in millimetres*

and secure the metal plate on the top of the assembly. Compress the powder using a hydraulic press by applying a suitable pressure for a sufficient dwell time to ensure a stable compact with minimal porosity; the disintegration of the compact has to be prevented as far as possible, since it would cause an increase in surface area and hence in dissolution rate. Detach the surface plate, and screw the die with punch still in place into the holder. Tighten securely. Remove all loose powder from the surface of the die by blowing compressed air or nitrogen across the surface of the compact.

Slide the die-holder assembly into the dissolution test chuck and tighten. Position the shaft in the spindle so that when the test head is lowered, the exposed surface of the compact will be 3.8 cm from the bottom of the vessel. The disc assembly is aligned to minimise wobble and air bubbles are not allowed to form as this could decrease the compact surface in contact with the dissolution medium. If possible, sink conditions are maintained throughout the test. However, in order to obtain detectable concentrations of solute, the use of a relatively small volume of medium may be necessary as a consequence of the limited surface available for dissolution.

Warm the dissolution medium to the temperature chosen for the test. Lower the test head into position before rotation. Care should be taken to ensure that air bubbles are excluded from the surface of the compact as this could decrease the compact surface in contact with the dissolution medium. Operate the apparatus immediately at the speed of rotation chosen for the test.

Collect samples at fixed time intervals and assay them by means of an analytical method of suitable sensitivity and accuracy.

ASSESSMENT OF THE RESULTS

The data for the cumulative amount dissolved at each time point are corrected for sampling losses. To calculate the intrinsic dissolution rate, plot the cumulative amount of sample dissolved per unit area of the compact against time. The cumulative amount dissolved per unit area is given by

the cumulative amount dissolved at each time point divided by the surface area exposed. Linear regression is then performed on the normalised experimental data relevant to an appropriate time interval preceding the possible disintegration of the compact. The intrinsic dissolution rate of the substance tested, expressed in milligrams per minute per square centimetre, is determined from the slope of the regression line. The result for intrinsic dissolution rate must be accompanied by a statement of the precise conditions of compact preparation and test method (dissolution medium, volume of medium used, stirring rate, temperature etc.).

NOTE: when necessary and justified, an apparatus with a different configuration may be used, such as a die holder that holds the compact in a fixed vertical position, with agitation provided by a paddle positioned at a defined distance from the surface of the compact.

2.9.31. PARTICLE SIZE ANALYSIS BY LASER LIGHT DIFFRACTION

The method is based on the ISO standards 13320-1(1999) and 9276-1(1998).

INTRODUCTION

The laser light diffraction technique used for the determination of particle-size distribution is based on the analysis of the diffraction pattern produced when particles are exposed to a beam of monochromatic light. Historically, the early laser diffraction instruments only used scattering at small angles. However, the technique has since been broadened to include laser light scattering in a wider angular range and application of the Mie theory, in addition to the Fraunhofer approximation and anomalous diffraction.

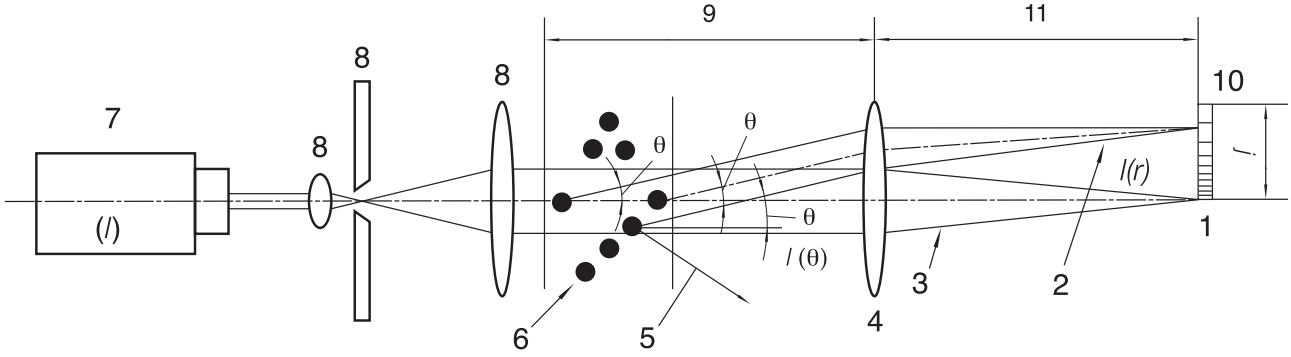
The technique cannot distinguish between scattering by single particles and scattering by clusters of primary particles, i.e. by agglomerates or aggregates. As most particulate samples contain agglomerates or aggregates and as the focus of interest is generally on the size distribution of primary particles, the clusters are usually dispersed into primary particles before measurement.

For non-spherical particles, an equivalent sphere-size distribution is obtained because the technique assumes spherical particles in its optical model. The resulting particle-size distribution may differ from those obtained by methods based on other physical principles (e.g. sedimentation, sieving).

This chapter provides guidance for the measurement of size distributions of particles in different dispersed systems, for example, powders, sprays, aerosols, suspensions, emulsions, and gas bubbles in liquids, through analysis of their angular light-scattering patterns. It does not address specific requirements of particle size measurement of specific products.

PRINCIPLE

A representative sample, dispersed at an adequate concentration in a suitable liquid or gas, is passed through a beam of monochromatic light, usually a laser. The light scattered by the particles at various angles is measured by a multi-element detector. Numerical values representing the scattering pattern are then recorded for subsequent analysis. These scattering pattern values are then transformed, using an appropriate optical model and mathematical procedure, to yield the proportion of total volume to a discrete number of size classes, forming a volumetric particle-size distribution.



APPARATUS

An example of a set-up of a laser light diffraction instrument is given in Figure 2.9.31.-1. Other equipment may be used.

The instrument comprises a laser light source, beam processing optics, a sample measurement region (or cell), a Fourier lens, and a multi-element detector for measuring the scattered light pattern. A data system is also required for deconvolution of the scattering data into a volumetric size distribution and associated data analysis and reporting.

The particles can enter the laser beam in 2 positions. In the conventional case the particles enter the parallel beam before the collecting lens and within its working distance. In so-called reversed Fourier optics the particles enter behind the collecting lens and thus, in a converging beam. The advantage of the conventional set-up is that a reasonable path length for the sample is allowed within the working distance of the lens. The second set-up allows only small path lengths but enables measurement of scattered light at larger angles, which is useful when submicron particles are present.

The interaction of the incident light beam and the ensemble of dispersed particles results in a scattering pattern with different light intensities at various angles. The total angular intensity distribution, consisting of both direct and scattered light, is then focused onto a multi-element detector by a lens or a series of lenses. These lenses create a scattering pattern that, within limits, does not depend on the location of the

11. Focal distance of lens (4)

Figure 2.9.31.-1. - *Example of a set-up of a laser light diffraction instrument*

particles in the light beam. Hence, the continuous angular intensity distribution is converted into a discrete spatial intensity distribution on a set of detector elements.

It is assumed that the measured scattering pattern of the particle ensemble is identical to the sum of the patterns from all individual single scattering particles presented in random relative positions. Note that only a limited angular range of scattered light is collected by the lens(es) and, therefore, by the detector.

DEVELOPMENT OF THE METHOD

Traditionally, the measurement of particle size using laser diffraction has been limited to particles in the range of approximately 0.1 μm to 3 mm. Because of recent advances in lens and equipment design, newer instruments are capable of exceeding this range routinely. With the validation report the user demonstrates the applicability of the method for its intended use.

Sampling. The sampling technique must be adequate to obtain a representative sample of a suitable volume for the particle-size measurement.

Evaluation of the dispersion procedure. The dispersion procedure must be adjusted to the purpose of the measurement. The purpose may be such that it is preferable to deagglomerate clusters into primary particles as far as possible, or it may be desirable to retain clusters as intact as possible. In this sense, the particles of interest may be either primary particles or clusters.

For the development of a method it is highly advisable to check that comminution of the particles does not occur, and conversely, that dispersion of particles or clusters is satisfactory. This can usually be done by changing the dispersing energy and monitoring the change of the particle-size distribution. The measured size distribution must not change significantly when the sample is well dispersed and the particles are neither fragile nor soluble. In addition, the particles of interest can be inspected visually or with the aid of a microscope. Moreover, if the manufacturing process (e.g. crystallisation, milling) of the material has changed, the applicability of the method must be verified (e.g. by microscopic comparison).

Sprays, aerosols and gas bubbles in a liquid should be measured directly, provided that their concentration is adequate, because sampling or dilution generally alters the particle-size distribution.

In other cases (such as emulsions, pastes and powders), representative samples may be dispersed in suitable liquids. Dispersing aids (wetting agents, stabilisers) and/or mechanical forces (e.g. agitation, sonication) are often applied for deagglomeration or deaggregation of clusters and stabilisation of the dispersion. For these liquid dispersions, a recirculating system is most commonly used, consisting of an optical measuring cell, a dispersion bath usually equipped with stirrer and ultrasonic elements, a pump, and tubing. Non-recirculating, stirred cells are useful when only small amounts of a sample are available or when special dispersion liquids are used.

Dry powders can also be converted into aerosols through the use of suitable dry powder dispersers, which apply mechanical force for deagglomeration or deaggregation. Generally, the dispersers use the energy of compressed gas or the differential pressure of a vacuum to disperse the particles to an aerosol, which is blown through the measuring zone, usually into the inlet of a vacuum unit that collects the particles. However, for free flowing, coarser particles or granules the effect of gravity may be sufficient to disperse the particles adequately.

Optimisation of the liquid dispersion. Liquids, surfactants, and dispersing aids used to disperse powders must:

- be transparent at the laser wavelength and practically free from air bubbles or particles;
- have a refractive index that differs from that of the test material;
- be non-solvent of the test material (pure liquid or pre-filtered, saturated solution);
- not alter the size of the test materials (e.g. by solubility, solubility enhancement, or recrystallisation effects);
- favour easy formation and stability of the dispersion;
- be compatible with the materials used in the instrument (such as O-rings, gaskets, tubing, etc.);
- possess a suitable viscosity to facilitate recirculation, stirring and filtration.

Surfactants and/or dispersing aids are often used to wet the particles and to stabilise the dispersion. For weak acids and weak bases, buffering of the dispersing medium at low or high pH respectively can assist in identifying a suitable dispersant.

A preliminary check of the dispersion quality can be performed by visual or microscopic inspection. It is also possible to take fractional samples out of a well-mixed stock dispersion. Such stock dispersions are formed by adding a liquid to the sample while mixing it with, for example, a glass rod, a spatula or a vortex mixer. Care must be taken to ensure a representative transfer of the sample and that settling of larger particles does not occur.

Optimisation of the gas dispersion. For sprays and dry powder dispersions, a compressed gas free from oil, water and particles may be used. To remove such materials from the compressed gas, a dryer with a filter can be used. Any vacuum unit should be located away from the measurement zone, so that its output does not disturb the measurement.

Determination of the concentration range. In order to produce an acceptable signal-to-noise ratio in the detector, the particle concentration in the dispersion must exceed a minimum level. Likewise, it must be below a maximum level in order to avoid multiple scattering. The concentration range is influenced by the width of the laser beam, the path length of the measurement zone, the optical properties of the particles, and the sensitivity of the detector elements.

In view of the above, measurements must be performed at different particle concentrations to determine the appropriate concentration range for any typical sample of material. (Note: in different instruments, particle concentrations are usually represented by differently scaled and differently named numbers, e.g. obscuration, optical concentration, proportional number of total mass).

Selection of an appropriate optical model. Most instruments use either the Fraunhofer or the Mie theory, though other approximation theories are sometimes applied for calculation of the scattering matrix. The choice of the theoretical model depends on the intended application and the different assumptions (size, absorbance, refractive index, roughness, crystal orientation, mixture, etc.) made for the test material. If the refractive index values (real and imaginary parts for the used wavelength) are not exactly known, then the Fraunhofer approximation or the Mie theory with a realistic estimate of the refractive index can be used. The former has the advantages that it is simple, it does not need refractive index values and it is extremely useful for analysis of powders coarser than about 1-2 μm; the latter usually provides less-biased particle-size distributions for small particles. In order to obtain traceable results, it is essential to document the refractive index values used, since small differences in

the values assumed for the real and imaginary part of the complex refractive index may cause significant differences in the measured particle-size distributions. Small values of the imaginary part of the refractive index (about 0.01 - 0.1 i) are often applied to allow the correction of the absorbance for the surface roughness of the particles.

Repeatability. The attainable repeatability of the method mainly depends on the characteristics of the material (milled/not milled, robust/fragile, width of its size distribution, etc.), whereas the required repeatability depends on the purpose of the measurement. Mandatory limits cannot be specified in this monograph, as repeatabilities (different sample preparations) may vary appreciably from one substance to another. However, it is good practice to aim at acceptance criteria for repeatability such as $s_{rel} \leq 10$ per cent [$n = 6$] for any central value of the distribution (e.g. for x_{50}). Values at the sides of the distribution (e.g. x_{10} and x_{90}) are oriented towards less stringent acceptance criteria such as $s_{rel} \leq 15$ per cent [$n = 6$]. Below 10 µm, these values must be doubled.

MEASUREMENT

Precautions. The instructions given in the apparatus manual are followed:

- never look into the direct path of the laser beam or its reflections;
- earth all apparatus components to prevent ignition of solvents or dust explosions;
- check the apparatus set-up (e.g. warm-up, required measuring range and lens, appropriate working distance, position of the detector, no direct bright daylight);
- in the case of wet dispersions, avoid air bubbles, evaporation of liquid, schlieren or other inhomogeneities in the dispersion; similarly, avoid improper mass-flow from the disperser or turbulent air-flow in the case of dry dispersions; such effects can cause erroneous particle-size distributions.

Measurement of the light scattering of dispersed sample(s). After proper alignment of the optical part of the instrument, a blank measurement of the particle-free dispersion medium must be performed. The background signal must be below an appropriate threshold.

Generally, the time for measurement permits a large number of detector scans or sweeps at short time intervals. For each detector element, an average signal is calculated, sometimes together with its standard deviation. The magnitude of the signal from each detector element depends upon the detection area, the light intensity and the quantum efficiency. The co-ordinates (size and position) of the detector elements together with the focal distance of the lens determine the range of scattering angles for each element. Most instruments also measure the intensity of the central (unscattered) laser beam. The ratio of the intensity of a dispersed sample to that in its absence (a blank measurement) indicates the proportion of scattered light and hence the particle concentration.

Conversion of scattering pattern into particle-size distribution. This deconvolution step is the inverse of the calculation of a scattering pattern for a given particle-size distribution. The assumption of spherical particle shape is particularly important as most algorithms use the mathematical solution for scattering from spherical particles. Furthermore, the measured data always contain some random and systematic errors, which may vitiate the size distributions. Several mathematical procedures have been developed for use in the available instruments. They contain some weighting of deviations between measured and calculated scattering patterns (e.g. least squares), some constraints (e.g. non-negativity for amounts of particles), and/or some smoothing of the size distribution curve. The algorithms used are specific to each make and model of equipment, and are proprietary. The differences in the algorithms between different instruments may give rise to differences in the calculated particle size statistics.

Replicates. It is recommended that the number of replicate measurements (with individual sample preparations) to be performed per sample is defined, in a substance-specific method.

REPORTING OF RESULTS

The particle size analysis data are usually reported as cumulative undersize distribution and/or as density distribution by volume. The symbol x is used to denote the particle size, which in turn is defined as the diameter of a volume-equivalent sphere. Q3(x) denotes the volume fraction undersize at the particle size x. In a graphical representation, x is plotted on the abscissa and the dependent variable Q3 on the ordinate. Most common characteristic values are calculated from the particle size distribution by interpolation. The particle sizes at the undersize values of 10 per cent, 50 per cent, and 90 per cent (denoted as x_{10}, x_{50}, and x_{90} respectively) are frequently used. x_{50} is also known as the median particle size. It is recognised that the symbol d is also widely used to designate the particle size, thus the symbol x may be replaced by d.

Moreover, sufficient information must be documented about the sample, the sample preparation, the dispersion conditions, and the cell type. As the results depend on the particular instrument, data analysis program, and optical model used, these details must also be documented.

CONTROL OF THE APPARATUS PERFORMANCE

Use the apparatus according to the manufacturer's instructions and carry out the prescribed verifications at an appropriate frequency, according to the use of the apparatus and substances to be tested.

Calibration. Laser diffraction systems, although assuming idealised properties of the particles, are based on first principles of laser light scattering. Thus, calibration in the strict sense is not required. However, it is still necessary to confirm that the instrument is operating correctly. This can be undertaken using any certified or standard reference material that is acceptable in industrial practice. The entire measurement procedure is examined, including sample collection, sample dispersion, sample transport through the measuring zone, measurement, and the deconvolution procedure. It is essential that the total operational procedure is fully described.

The preferred certified or standard reference materials consist of spherical particles of a known distribution ranging over one decade of size. They must be certified as to the mass-percentage size distribution by an absolute technique, if available, and used in conjunction with an agreed, detailed operation procedure. It is essential that the real and imaginary parts of the complex refractive index of the material are indicated if the Mie theory is applied in data analysis. The representation of the particle-size distribution by volume will equal that of the distribution by mass, provided that the density of the particles is the same for all size fractions.

The response of a laser diffraction instrument is considered to meet the requirements if the mean value of x_{50} from at least 3 independent measurements does not deviate by more than 3 per cent from the certified range of values of the certified or standard reference material, i.e. the mean value together

with its standard deviation. The mean values for x_{10} and x_{90} must not deviate by more than 5 per cent from the certified range of values. Below 10 µm, these values must be doubled.

Although the use of materials consisting of spherical particles is preferable, non-spherical particles may also be employed. Preferably, these particles have certified or typical values from laser diffraction analyses performed according to an agreed, detailed operating procedure. The use of reference values from methods other than laser diffraction may cause a significant bias. The reason for this bias is that the different principles inherent in the various methods may lead to different sphere-equivalent diameters for the same non-spherical particle.

In addition to the certified reference materials mentioned above, product samples of typical composition and particle-size distribution for a specified class of products can also be used, provided their particle-size distribution has proven to be stable over time. The results must comply with previously determined data, with the same precision and bias as for the certified reference material.

Verification of the system. In addition to the calibration, the performance of the apparatus must be verified at regular time intervals or as frequently as appropriate. This can be undertaken using any suitable material as mentioned in the previous paragraph.

The verification of the system is based on the concept that the equipment, electronics, software and analytical operations constitute an integral system, which can be evaluated as an entity. Thus the entire measurement procedure is examined, including sample collection, sample dispersion, sample transport through the measuring zone, and the measurement and deconvolution procedure. It is essential that the total operational procedure is fully described.

In general, unless otherwise specified in the individual monograph, the response of a laser diffraction instrument is considered to meet the requirements if the x_{50} value does not deviate by more than 10 per cent from the range of values of the reference material, i.e. the mean value together with its standard deviation. If optionally the values at the sides of the distribution are evaluated (e.g. x_{10} and x_{90}), then these values must not deviate by more than 15 per cent from the certified range of values. Below 10 µm, these values must be doubled.

01/2008:20933

2.9.33. CHARACTERISATION OF CRYSTALLINE AND PARTIALLY CRYSTALLINE SOLIDS BY X-RAY POWDER DIFFRACTION (XRPD)

Every crystalline phase of a given substance produces a characteristic X-ray diffraction pattern.

Diffraction patterns can be obtained from a randomly oriented crystalline powder composed of crystallites or crystal fragments of finite size. Essentially 3 types of information can be derived from a powder diffraction pattern: angular position of diffraction lines (depending on geometry and size of the unit cell); intensities of diffraction lines (depending mainly on atom type and arrangement, and particle orientation within the sample); and diffraction line profiles (depending on instrumental resolution, crystallite size, strain and specimen thickness).

Experiments giving angular positions and intensities of lines can be used for applications such as qualitative phase analysis (for example, identification of crystalline phases) and quantitative phase analysis of crystalline materials. An estimate of the amorphous and crystalline fractions[6] can also be made.

In addition, analysis of line-profile broadening can also allow the determination of crystallite size (size of coherently scattering domains) and micro-strain.

The X-ray powder diffraction (XRPD) method provides an advantage over other means of analysis in that it is usually non-destructive in nature (specimen preparation is usually limited to grinding to ensure a randomly oriented sample). XRPD investigations can also be carried out under *in situ* conditions on specimens exposed to non-ambient conditions, such as low or high temperature and humidity.

PRINCIPLE

X-ray diffraction results from the interaction between X-rays and electron clouds of atoms. Depending on the atomic arrangement, interferences arise from the scattered X-rays. These interferences are constructive when the path difference between 2 diffracted X-ray waves differs by an integral number of wavelengths. This selective condition is described by the Bragg equation, also called Bragg's law (see Figure 2.9.33.-1):

$$2 d_{\mathrm{hkl}} \sin \theta_{\mathrm{hkl}} = \mathrm{n}\lambda$$

The wavelength λ of the X-rays is of the same order of magnitude as the distance between successive crystal lattice planes, or d_{hkl} (also called 'd-spacings'). θ_{hkl} is the angle between the incident ray and the family of lattice planes, and $\sin\theta_{hkl}$ is inversely proportional to the distance between successive crystal planes or d-spacings.

The direction and spacing of the planes with reference to the unit cell axes are defined by the Miller indices {*hkl*}. These indices are the reciprocals, reduced to the next-lower integer, of the intercepts that a plane makes with the unit cell axes. The unit cell dimensions are given by the spacings *a*, *b* and *c* and the angles between them, α, β, and γ.

The interplanar spacing for a specified set of parallel *hkl* planes is denoted by d_{hkl}. Each such family of planes may show higher orders of diffraction where the *d* values for the related families of planes n*h*, n*k*, n*l* are diminished by the factor 1/n (n being an integer: 2,3,4, etc.).

Every set of planes throughout a crystal has a corresponding Bragg diffraction angle, θ_{hkl}, associated with it (for a specific wavelength λ).

A powder specimen is assumed to be polycrystalline so that at any angle θ_{hkl} there are always crystallites in an orientation allowing diffraction according to Bragg's law[7]. For a given X-ray wavelength, the positions of the diffraction peaks (also referred to as 'lines', 'reflections' or 'Bragg reflections') are characteristic of the crystal lattice (d-spacings), their theoretical intensities depend on the crystallographic unit cell content (nature and positions of atoms), and the line profiles on the perfection and extent of the crystal lattice. Under these conditions the diffraction peak has a finite

(6) There are many other applications of the X-ray powder diffraction technique that can be applied to crystalline pharmaceutical substances such as: determination of crystal structures, refinement of crystal structures, determination of crystallographic purity of crystalline phases, characterisation of crystallographic texture, etc. These applications are not described in this chapter.
(7) An 'ideal' powder for diffraction experiments consists of a large number of small, randomly oriented spherical crystallites (coherently diffracting crystalline domains). If this number is sufficiently large, there are always enough crystallites in any diffracting orientation to give reproducible diffraction patterns. To obtain a precise measurement of the intensity of diffracted X-rays, it is recommended that the crystallite size be small, i.e. typically 10 µm or less, depending on the characteristics of the specimen (X-ray absorption, shape, etc.) and the diffraction geometry.

intensity arising from atomic arrangement, type of atoms, thermal motion and structural imperfections, as well as from instrument characteristics.

The main characteristics of diffraction line profiles are 2θ position, peak height, peak area and shape (characterised by, for example, peak width or asymmetry, analytical function, empirical representation). An example of the type of powder patterns obtained for 5 different solid phases of a substance[(8)] are shown in Figure 2.9.33.-2.

In addition to the diffraction peaks, an X-ray diffraction experiment also generates a more-or-less uniform background, upon which the peaks are superimposed. Besides specimen preparation, other factors contribute to the background, for instance the sample holder, diffuse scattering from air and equipment, other instrumental parameters such as detector noise, general radiation from the X-ray tube, etc. The peak to background ratio can be increased by minimising background and by choosing prolonged exposure times.

APPARATUS

Instrument set-up. X-ray diffraction experiments are usually performed using powder diffractometers or powder cameras.

A powder diffractometer generally comprises 5 main parts: an X-ray source; incident beam optics, which may perform monochromatisation, filtering, collimation and/or focusing of the beam; a goniometer; diffraction beam optics, which may perform monochromatisation, filtering, collimation and focusing or parallelising of the beam; and a detector. Data collection and data processing systems are also required and are generally included in current diffraction measurement equipment.

Depending on the type of analysis to be performed (phase identification, quantitative analysis, lattice parameters determination, etc.), different XRPD instrument configurations and performance levels are required. The simplest instruments used to measure powder patterns are powder cameras. Of the various camera types available, there are 3 commonly employed instruments: the Debye-Scherrer, the Gandolfi and the Guinier focusing cameras. Replacement of photographic film as the detection method by photon detectors has led to the design of diffractometers in which the geometric arrangement of the optics is not truly focusing but parafocusing, such as in the Bragg-Brentano geometry. The Bragg-Brentano parafocusing configuration is currently the most widely used and is therefore briefly described here.

A given instrument may provide a horizontal or vertical θ/2θ geometry or a vertical θ/θ geometry. For both geometries, the incident X-ray beam forms an angle θ with the specimen plane and the diffracted X-ray beam forms an angle 2θ with the direction of the incident X-ray beam (an angle θ with the specimen plane). The basic geometric arrangement is represented in Figure 2.9.33.-3. The divergent beam of radiation from the X-ray tube (the so-called 'primary beam') passes through the parallel plate collimators and a divergence slit assembly and illuminates the flat surface of the specimen. All the rays diffracted by suitably oriented crystallites in the specimen at an angle 2θ converge to a line at the receiving slit. A second set of parallel plate collimators and a scatter slit may be placed either behind or before the receiving slit. The axes of the line focus and of the receiving slit are at equal distances from the axis of the goniometer. The X-ray quanta are counted by a radiation detector, usually a scintillation counter, a sealed-gas proportional counter, or a position-sensitive or solid-state detector. The receiving slit assembly and the detector are coupled together and move tangentially to the focusing circle. For θ/2θ scans the goniometer rotates the specimen about the same axis as that of the detector, but at half the rotational speed, in a θ/2θ motion. The surface of the specimen thus remains tangential to the focusing circle. The parallel plate collimator limits the axial divergence of the beam and hence partially controls the shape of the diffracted line profile.

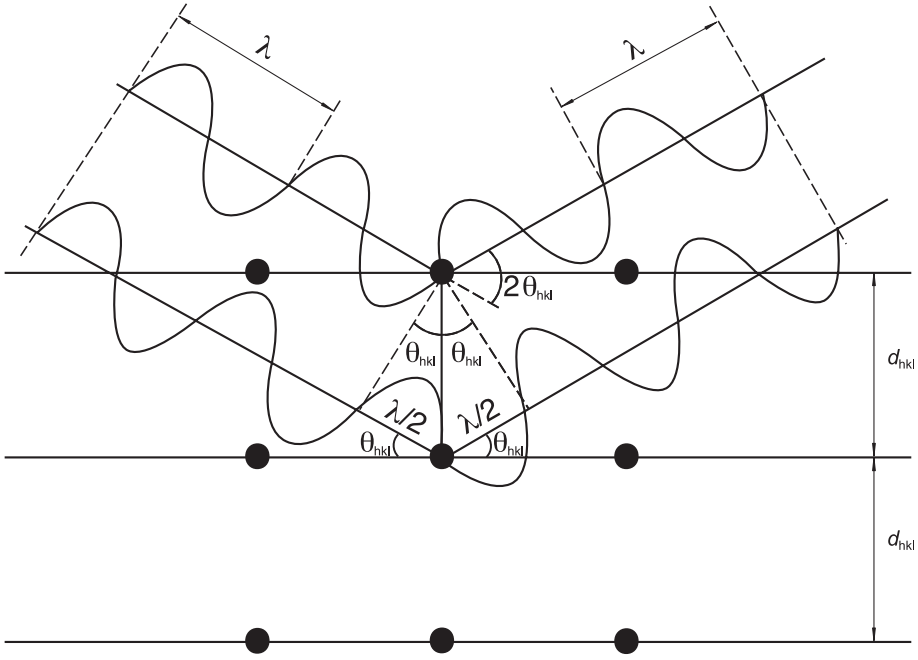

Figure 2.9.33.-1. – *Diffraction of X-rays by a crystal according to Bragg's law*

(8) These diffraction patterns were collected on a Siemens D500 diffractometer (Bragg-Brentano geometry) using a pure monochromatic CuKα1 radiation (λ = 0.1540598 nm) selected with an incident-beam curved-crystal germanium monochromator with asymmetric focusing (short focal distance 124 mm, long focal distance 216 mm). Detection of signal was achieved using a scintillation detector. To reduce the effect of transparency of the specimens, a thin layer of powder was deposited on an oriented single crystal silicon wafer. The alignment of the diffractometer was checked by means of the OOI reflections of fluorophlogopite mica (NIST SRM 675). The zero error was estimated as less than 0.01° (2θ). The instrumental resolution function of the set-up exhibits a shallow minimum of 0.065° (2θ) at about 40° (2θ) and has twice this value at 130° (2θ). For each phase, the diffraction pattern was scanned with the same step length of 0.02° (2θ), but with different fixed counting times [form A: 30 s; form B: 48 s; form C: 48 s; form D: 40 s; amorphous phase: 10 s].

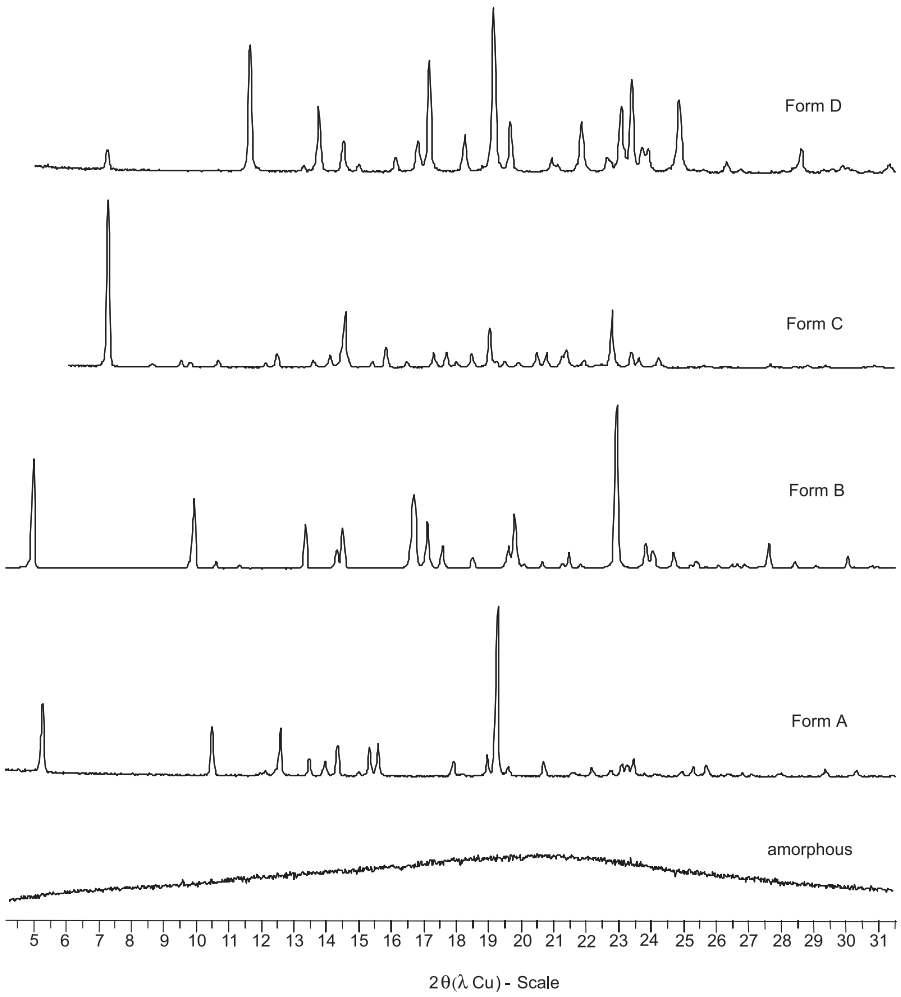

Figure 2.9.33.-2. – *X-ray powder patterns collected for 5 different solid phases of a substance (the intensities are normalised)*

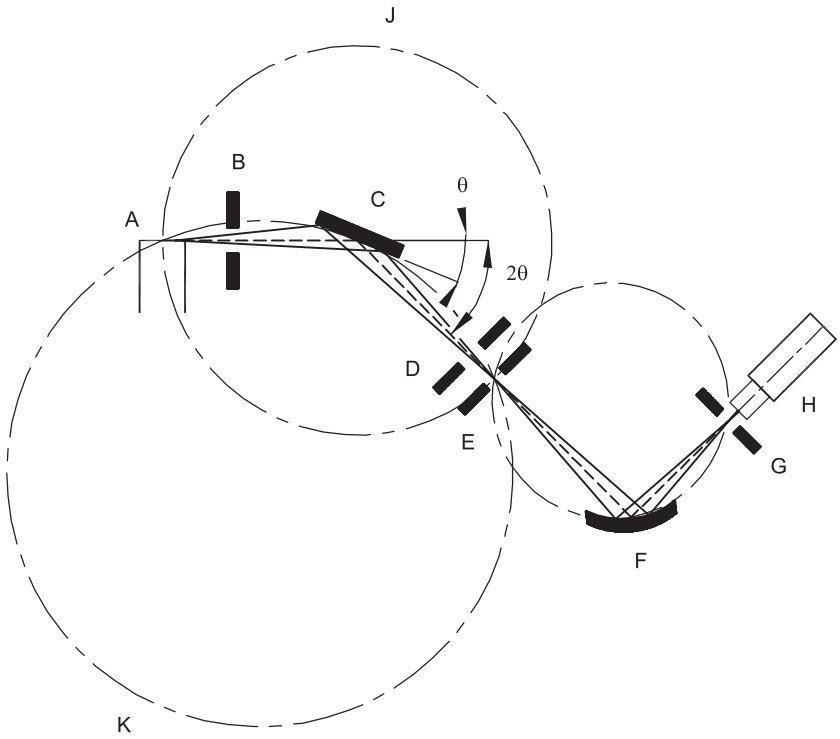

A Bragg-Brentano diffractometer may also be used in transmission mode. The advantage with this technology is to lessen the effects due to preferred orientation. A capillary of about 0.5-2 mm thickness can also be used for small sample amounts.

X-ray radiation. In the laboratory, X-rays are obtained by bombarding a metal anode with electrons emitted by the thermionic effect and accelerated in a strong electric field (using a high-voltage generator). Most of the kinetic energy of the electrons is converted to heat, which limits the power of the tubes and requires efficient anode cooling. A 20- to 30-fold increase in brilliance can be obtained using rotating anodes and by using X-ray optics. Alternatively, X-ray photons may be produced in a large-scale facility (synchrotron).

The spectrum emitted by an X-ray tube operating at sufficient voltage consists of a continuous background of polychromatic radiation and additional characteristic radiation that depends on the type of anode. Only this characteristic radiation is used in X-ray diffraction experiments. The principal radiation sources utilised for X-ray diffraction are vacuum tubes utilising copper, molybdenum, iron, cobalt or chromium as anodes; copper, molybdenum or cobalt X-rays are employed most commonly for organic substances (the use of cobalt anodes can be especially preferred to separate distinct X-ray lines). The choice of radiation to be used depends on the absorption characteristics of the specimen and possible fluorescence by atoms present in the specimen. The wavelengths used in powder diffraction generally correspond to the K_α radiation from the anode. Consequently, it is advantageous to make the X-ray beam 'monochromatic' by eliminating all the other components of the emission spectrum. This can be partly obtained using K_β filters, i.e. metal filters selected as having an absorption edge between the K_α and K_β wavelengths emitted by the tube.

Such a filter is usually inserted between the X-ray tube and the specimen. Another, more-and-more-commonly used way to obtain a monochromatic X-ray beam is via a large monochromator crystal (usually referred to as a 'monochromator'). This crystal is placed before or behind the specimen and diffracts the different characteristic peaks of the X-ray beam (i.e. K_α and K_β) at different angles, so that only one of them may be selected to enter into the detector. It is even possible to separate $K_{\alpha1}$ and $K_{\alpha2}$ radiations by using a specialised monochromator. Unfortunately, the gain in getting a monochromatic beam by using a filter or a monochromator is counteracted by a loss in intensity. Another way of separating K_α and K_β wavelengths is by using curved X-rays mirrors that can simultaneously monochromate and focus or parallelise the X-ray beam.

RADIATION PROTECTION. Exposure of any part of the human body to X-rays can be injurious to health. It is therefore essential that whenever X-ray equipment is used, adequate precautions are taken to protect the operator and any other person in the vicinity. Recommended practice for radiation protection as well as limits for the levels of X-radiation exposure are those established by national legislation in each country. If there are no official

regulations or recommendations in a country, the latest recommendations of the International Commission on Radiological Protection should be applied.

SPECIMEN PREPARATION AND MOUNTING

The preparation of the powdered material and mounting of the specimen in a suitable holder are critical steps in many analytical methods, and are particularly so for X-ray powder diffraction analysis, since they can greatly affect the quality of the data to be collected[9]. The main sources of error due to specimen preparation and mounting are briefly discussed here for instruments in Bragg-Brentano parafocusing geometry.

SPECIMEN PREPARATION

In general, the morphology of many crystalline particles tends to give a specimen that exhibits some degree of preferred orientation in the specimen holder. This is particularly evident for needle-like or plate-like crystals when size reduction yields finer needles or platelets. Preferred orientation in the specimen influences the intensities of various reflections, so that some are more intense and others are less intense, compared to what would be expected from a completely random specimen. Several techniques can be employed to improve randomness in the orientation of crystallites (and therefore to minimise preferred orientation), but further reduction of particle size is often the best and simplest approach. The optimum number of crystallites depends on the diffractometer geometry, the required resolution and the specimen attenuation of the X-ray beam. In some cases, particle sizes as large as 50 μm will provide satisfactory results in phase identification. For quantitative XRPD analysis, it is often recommended that the specimen have coherent domains (crystallites) with a size less than 10 μm. However, excessive milling (crystallite sizes less than approximately 0.5 μm) may cause line broadening and significant changes to the sample itself such as:

- specimen contamination by particles abraded from the milling instruments (mortar, pestle, balls, etc.);
- reduced degree of crystallinity;
- solid-state transition to another polymorph;
- chemical decomposition;
- introduction of internal stress;
- solid-state reactions.

Therefore, it is advisable to compare the diffraction pattern of the non-ground specimen with that corresponding to a specimen of smaller particle size (e.g. a milled specimen). If the X-ray powder pattern obtained is of adequate quality considering its intended use, then grinding may not be required.

It should be noted that if a sample contains more than one phase and if sieving is used to isolate particles to a specific size, the initial composition may be altered.

SPECIMEN MOUNTING

Effect of specimen displacement. A specimen surface that is offset by D with reference to the diffractometer rotation axis causes systematic errors that are very difficult to avoid entirely, resulting in absolute $D\cos\theta$ shifts[10] in 2θ positions (typically of the order of 0.01° in 2θ at low angles ($\cos\theta \simeq 1$) for a displacement D = 15 μm) and asymmetric broadening of the profile towards low 2θ values. Use of an appropriate internal standard allows the detection and correction of this effect simultaneously with that arising from specimen transparency. This is by far the largest source of errors in data collected on well-aligned diffractometers.

(9) Similarly, changes in the specimen can occur during data collection in the case of a non-equilibrium specimen (temperature, humidity).
(10) Note that a goniometer zero alignment shift would result in constant shift on all observed 2θ-line positions, in other words, the whole diffraction pattern is in this case translated by an offset of Z° in 2θ.

Effect of specimen thickness and transparency. When the XRPD method in reflection mode is applied, it is often preferable to work with specimens of 'infinite thickness'. This means that, for a given mass attenuation and bulk density of the specimen and a given range of diffraction angles, the diffracted intensity from the back of the specimen is negligible. For quantitative analysis, to ensure that the diffracted intensity is at least 99.9 per cent of the maximum attainable by increasing the specimen thickness *t*, the thickness must be at least:

$$t = 3.45 \sin \theta / \mu' \rho'$$

- μ' = mass attenuation coefficient (often referred to as the mass absorption coefficient);
- ρ' = bulk density of the specimen.

μ' is additive for the mass attenuation coefficients of the individual elements that constitute the material. It is independent of the physical state of the material.

For specimens with low attenuation (such as organic materials where the linear absorption coefficients are very small), the diffracted intensity appears to originate from a position below the surface resulting in line shifts and changes in line widths. This effect, referred to as the transparency effect, is large for thick specimens with low attenuation and can lead to angular errors of as much as a tenth of a degree. For such specimens, a precise measurement of line positions can be carried out on a specimen that is as thin as possible, but which still gives acceptable diffraction intensities. It is advisable to use a non-diffracting substrate (zero background holder), for example a plate of single crystalline silicon cut parallel to the 510 lattice planes[(11)]. One advantage of the transmission mode is that problems with sample height and specimen transparency are less important.

The use of an appropriate internal standard allows the detection and correction of this effect simultaneously with that arising from specimen displacement.

DIFFRACTOMETER ALIGNMENT

Goniometers and the corresponding incident and diffracted X-ray beam optics have many mechanical parts that need adjustment. The degree of alignment or misalignment directly influences the quality of the results of an XRPD investigation. Therefore, the different components of the diffractometer must be carefully adjusted (optical and mechanical systems, etc.) to adequately minimise systematic errors, while optimising the intensities received by the detector. The search for maximum intensity and maximum resolution is always antagonistic when aligning a diffractometer. Hence, the best compromise must be sought whilst performing the alignment procedure. There are many different configurations and each supplier's equipment requires specific alignment procedures.

CALIBRATION, PERFORMANCE TESTING AND MONITORING OF DIFFRACTOMETERS

To establish the magnitude of potential errors in the diffractometer, a calibration curve, using a proper calibrant, whether internal or external, can be prepared after the alignment of the diffractometer for each of the following:

- angular calibration;
- intensity calibration;
- line shape calibration.

The calibration is usually performed using certified reference standards (choice is dependent on type of analysis). The overall diffractometer performance should be tested and monitored periodically using working standards and/or reference standards (depending on the type of analysis).

QUALITATIVE PHASE ANALYSIS (IDENTIFICATION OF PHASES)

The identification of the phase composition of an unknown sample by XRPD is usually based on the visual or computer-assisted comparison of a portion of its X-ray powder pattern to the experimental or calculated pattern of a reference material. Ideally, these reference patterns are collected on well-characterised single-phase specimens. This approach makes it possible in most cases to identify a crystalline substance by its 2θ diffraction angles or d-spacings and by its relative intensities. The computer-aided comparison of the diffraction pattern of the unknown sample to the comparison data can be based either on a more-or-less extended 2θ-range of the whole diffraction pattern or on a set of reduced data derived from the pattern. For example, the list of d-spacings and normalised intensities I_{norm}, a so-called (d, I_{norm})-list extracted from the pattern, is the crystallographic fingerprint of the material, and can be compared to (d, I_{norm})-lists of single-phase samples compiled in databases.

For most organic crystals, when using Cu K_α radiation, it is appropriate to record the diffraction pattern in a 2θ-range from as near 0° as possible to at least 40°. The agreement in the 2θ-diffraction angles between specimen and reference is within 0.1° for the same crystal form, while relative intensities between specimen and reference may vary considerably due to preferred orientation effects. For other types of samples (e.g. inorganic salts), it may be necessary to extend the 2θ-region scanned to well beyond 40°. It is generally sufficient to scan past the 10 strongest reflections identified in single phase X-ray powder diffraction database files.

It is sometimes difficult or even impossible to identify phases in the following cases:

- non-crystallised or amorphous substances;
- the components to be identified are present in low mass fractions of the analyte amounts (generally less than 10 per cent *m/m*);
- pronounced preferred orientation effects;
- the phase has not been filed in the database used;
- formation of solid solutions;
- presence of disordered structures that alter the unit cell;
- the specimen comprises too many phases;
- presence of lattice deformations;
- structural similarity of different phases.

QUANTITATIVE PHASE ANALYSIS

If the sample under investigation is a mixture of 2 or more known phases, of which not more than 1 is amorphous, the percentage (by volume or by mass) of each crystalline phase and of the amorphous phase can, in many cases, be determined. Quantitative phase analysis can be based on the integrated intensities, on the peak heights of several individual diffraction lines[(12)], or on the full pattern. These integrated intensities, peak heights or full-pattern data points are compared to the corresponding values of reference materials. These reference materials shall be single-phase

(11) In the case of a thin specimen with low attenuation, accurate measurements of line positions can be made with focusing diffractometer configurations in either transmission or reflection geometry. Accurate measurements of line positions on specimens with low attenuation are preferably made using diffractometers with parallel beam optics. This helps to reduce the effects of specimen thickness.

(12) If the crystal structures of all components are known, the Rietveld method can be used to quantify them with good accuracy. If the crystal structures of the components are not known, the Pawley method or Partial Least Squares (PLS) method can be used.

or a mixture of known phases. The difficulties encountered during quantitative analysis are due to specimen preparation (the accuracy and precision of the results require in particular homogeneity of all phases and a suitable particle size distribution in each phase) and to matrix effects.

MATRIX EFFECTS

Matrix-effects corrections consist of eliminating or estimating the absorption phenomenon, except in the case of mixtures of polymorphic samples in which all phases have the same absorption coefficients. However, it should be noted that in the case of organic systems, such effects are rather limited, hence corrections can in many such cases be neglected.

POLYMORPHIC SAMPLES

For a sample composed of 2 polymorphic phases *a* and *b*, the following relationship can be written for the fraction F_a of phase *a*:

$$F_a = \frac{1}{1 + K\,(I_b/I_a)}$$

The fraction is derived by measuring the intensity ratio between the 2 phases, knowing the value of the constant *K*. *K* is the ratio of the absolute intensities of the 2 pure polymorphic phases I_{oa}/I_{ob}. Its value can be determined by measuring standard samples.

METHODS USING A STANDARD

The most commonly used methods for quantitative analysis are:

- the 'external standard method';
- the 'internal standard method';
- the 'spiking method' (often also called the 'standard addition method').

The 'external standard method' is the most general method and consists of comparing the X-ray diffraction pattern of the mixture, or the respective line intensities, with those measured in a reference mixture or with the theoretical intensities of a structural model, if it is fully known.

To limit errors due to matrix effects, an internal reference material with crystallite size and X-ray absorption coefficient comparable to those of the components of the sample, and with a diffraction pattern that does not overlap at all that of the sample to be analysed, can be used. A known quantity of this reference material is added to the sample to be analysed and to each of the reference mixtures. Under these conditions, a linear relationship between line intensity and concentration exists. This application, called the 'internal standard method', requires a precise measurement of diffraction intensities.

In the 'spiking method' (or 'standard addition method'), some of the pure phase *a* is added to the mixture containing the unknown concentration of *a*. Multiple additions are made to prepare an intensity-versus-concentration plot in which the negative *x* intercept is the concentration of the phase *a* in the original sample.

ESTIMATE OF THE AMORPHOUS AND CRYSTALLINE FRACTIONS

In a mixture of crystalline and amorphous phases, the crystalline and amorphous fractions can be estimated in several ways. The choice of the method used depends on the nature of the sample:

- if the sample consists of crystalline fractions and an amorphous fraction of different chemical compositions, the amounts of each of the individual crystalline phases may be estimated using appropriate standard substances as described above; the amorphous fraction is then deduced indirectly by subtraction;
- if the sample consists of one amorphous and one crystalline fraction, either as a 1-phase or a 2-phase mixture, with the same elemental composition, the amount of the crystalline phase ('the degree of crystallinity') can be estimated by measuring 3 areas of the diffractogram:

  A = total area of the peaks arising from diffraction from the crystalline fraction of the sample;

  B = total area below area A;

  C = background area (due to air scattering, fluorescence, equipment, etc).

When these areas have been measured, the degree of crystallinity can be roughly estimated using the following formula:

$$\%\,\text{crystallinity} = 100A/(A + B - C)$$

It is noteworthy that this method does not yield absolute degree-of-crystallinity values and hence is generally used for comparative purposes only.

More sophisticated methods are also available, such as the Ruland method.

OBTAINING STRUCTURAL INFORMATION FROM XRPD PATTERN

Powder X-ray diffraction has been an important standard tool for many decades for identifying and characterising crystalline materials. Recent developments in XRPD methods also allow some relevant structural information to be extracted from accurate XRPD data, as briefly described below.

Determination of lattice parameters. In an X-ray powder diffraction pattern, each line can be associated with a d-spacing and the Miller indices {*hkl*} of the corresponding family or families of planes, if the unit cell of the lattice is known (crystal system, Bravais lattice, approximate lattice parameters). The d-spacings measured from the diffractogram are related to the lattice parameters by geometric relations involving the Miller indices of the planes considered. If the material studied consists of crystalline phases for which the corresponding lattice parameters are approximately known, the lattice parameters can be refined by a least squares method using the whole powder pattern or a list of indexed d-spacings.

If the material studied consists of an unknown crystalline phase, the determination of the lattice parameters requires *ab initio* indexing of the XRPD pattern. This results in Miller indices being attributed to each line of the observed diffractogram. It can be accomplished by comparison with a reference pattern or by automatic indexing programs. Whether the mathematical solution found by an automatic indexing program is the true crystallographic unit cell or only a 'pseudo-cell' depends on the completeness and uncertainty of the experimental data and on the size and symmetry of the unit cell.

Structure solution. In general, the determination of crystal structures is performed from X-ray diffraction data obtained using single crystals. However, when substances cannot be prepared in the appropriate pure crystallographic form, this conventional approach cannot be employed. Recent developments based on high-resolution X-ray diffraction techniques using powders have led to significant progress in crystal structure determination. Crystal structures can sometimes be determined from sufficiently well-resolved powder diffraction data by applying trial and error, Patterson methods and/or direct methods. However, crystal structure analysis of organic crystals is a challenging task,

since the lattice parameters are comparatively large, the symmetry is low and the scattering properties are normally very low. For any given crystalline form of a substance, knowledge of the crystal structure allows the calculation of the corresponding XRPD pattern, thereby providing a 'preferred-orientation-free' reference XRPD pattern, which can then be used for batch comparisons.

Refinement of crystal structures. Refinement of crystal structures consists of minimising the difference between the intensities of the experimental diffraction pattern of a crystalline substance and the intensities calculated from a structural model sufficiently close to the true structure. The minimisation is carried out using a least squares method (or other procedure) to refine the structural parameters of the model (unit cell dimensions, atom co-ordinates, site occupancies) and the atomic displacement parameters, until a satisfactory agreement between calculated and observed intensities is obtained. This application requires accurate diffraction data (intensity and position), containing sufficient information to estimate the structural parameters concerned. Structure refinement is most often carried out by Rietveld-type methods, but the integrated intensity method can also be applied.

2.9.36. POWDER FLOW

The widespread use of powders in the pharmaceutical industry has generated a variety of methods for characterising powder flow. Not surprisingly, scores of references appear in the pharmaceutical literature, attempting to correlate the various measures of powder flow to manufacturing properties. The development of such a variety of test methods was inevitable; powder behavior is multifaceted and thus complicates the effort to characterise powder flow.

The purpose of this chapter is to review the methods for characterising powder flow that have appeared most frequently in the pharmaceutical literature. In addition, while it is clear that no single and simple test method can adequately characterise the flow properties of pharmaceutical powders, this chapter proposes the standardisation of test methods that may be valuable during pharmaceutical development.

4 commonly reported methods for testing powder flow are:

- angle of repose,
- compressibility index or Hausner ratio,
- flow rate through an orifice,
- shear cell.

In addition, numerous variations of each of these basic methods are available. Given the number of test methods and variations, standardising the test methodology, where possible, would be advantageous.

With this goal in mind, the most frequently used methods are discussed below. Important experimental considerations are identified and recommendations are made regarding standardisation of the methods. In general, any method of measuring powder flow must be practical, useful, reproducible and sensitive, and must yield meaningful results. It bears repeating that no simple powder flow method will adequately or completely characterise the wide range of flow properties experienced in the pharmaceutical industry. An appropriate strategy may well be the use of multiple standardised test methods to characterise the various aspects of powder flow as needed by the pharmaceutical scientist.

ANGLE OF REPOSE

The angle of repose has been used in several branches of science to characterise the flow properties of solids. Angle of repose is a characteristic related to interparticulate friction, or resistance to movement between particles. Angle of repose test results are reported to be very dependent upon the method used. Experimental difficulties arise due to segregation of material and consolidation or aeration of the powder as the cone is formed. Despite its difficulties, the method continues to be used in the pharmaceutical industry, and a number of examples demonstrating its value in predicting manufacturing problems appear in the literature.

The angle of repose is the constant, three-dimensional angle (relative to the horizontal base) assumed by a cone-like pile of material formed by any of several different methods, described briefly below.

Basic methods for angle of repose

A variety of angle of repose test methods are described in the literature. The most common methods for determining the static angle of repose can be classified based on 2 important experimental variables:

- the height of the 'funnel' through which the powder passes may be fixed relative to the base, or the height may be varied as the pile forms;
- the base upon which the pile forms may be of fixed diameter or the diameter of the powder cone may be allowed to vary as the pile forms.

Variations in angle of repose methods

Variations of the above methods have also been used to some extent in the pharmaceutical literature:

- *drained angle of repose*: this is determined by allowing an excess quantity of material positioned above a fixed diameter base to "drain" from the container. Formation of a cone of powder on the fixed diameter base allows determination of the drained angle of repose;
- *dynamic angle of repose*: this is determined by filling a cylinder (with a clear, flat cover on one end) and rotating it at a specified speed. The dynamic angle of repose is the angle (relative to the horizontal) formed by the flowing powder. The internal angle of kinetic friction is defined by the plane separating those particles sliding down the top layer of the powder and those particles that are rotating with the drum (with roughened surface).

General scale of flowability for angle of repose

While there is some variation in the qualitative description of powder flow using the angle of repose, much of the pharmaceutical literature appears to be consistent with the classification by Carr[1], which is shown in Table 2.9.36.-1. There are examples in the literature of formulations with an angle of repose in the range of 40-50 degrees that manufactured satisfactorily. When the angle of repose exceeds 50 degrees, the flow is rarely acceptable for manufacturing purposes.

Table 2.9.36.-1. – *Flow properties and corresponding angles of repose*[1]

Flow property	Angle of repose (degrees)
Excellent	25-30
Good	31-35
Fair (aid not needed)	36-40
Passable (may hang up)	41-45
Poor (must agitate, vibrate)	46-55
Very poor	56-65
Very, very poor	> 66

(1) Carr RL. Evaluating flow properties of solids. *Chem. Eng* 1965; 72:163-168.

Experimental considerations for angle of repose

Angle of repose is not an intrinsic property of the powder, that is to say, it is very much dependent upon the method used to form the cone of powder. On this subject, the existing literature raises these important considerations:

– the peak of the cone of powder can be distorted by the impact of powder from above. By carefully building the powder cone, the distortion caused by impact can be minimised;
– the nature of the base upon which the powder cone is formed influences the angle of repose. It is recommended that the powder cone be formed on a 'common base', which can be achieved by forming the cone of powder on a layer of powder. This can be done by using a base of fixed diameter with a protruding outer edge to retain a layer of powder upon which the cone is formed.

Recommended procedure for angle of repose

Form the angle of repose on a fixed base with a retaining lip to retain a layer of powder on the base. The base must be free of vibration. Vary the height of the funnel to carefully build up a symmetrical cone of powder. Care must be taken to prevent vibration as the funnel is moved. The funnel height is maintained at approximately 2-4 cm from the top of the powder pile as it is being formed in order to minimise the impact of falling powder on the tip of the cone. If a symmetrical cone of powder cannot be successfully or reproducibly prepared, this method is not appropriate. Determine the angle of repose by measuring the height of the cone of powder and calculating the angle of repose, α, from the following equation:

$$\tan(\alpha) = \frac{\text{height}}{0.5 \times \text{base}}$$

COMPRESSIBILITY INDEX AND HAUSNER RATIO

In recent years the compressibility index and the closely related Hausner ratio have become the simple, fast, and popular methods of predicting powder flow characteristics. The compressibility index has been proposed as an indirect measure of bulk density, size and shape, surface area, moisture content, and cohesiveness of materials, because all of these can influence the observed compressibility index. The compressibility index and the Hausner ratio are determined by measuring both the bulk volume and tapped volume of a powder.

Basic methods for compressibility index and Hausner ratio

While there are some variations in the method of determining the compressibility index and Hausner ratio, the basic procedure is to measure the unsettled apparent volume, (V_0), and the final tapped volume, (V_f), of the powder after tapping the material until no further volume changes occur. The compressibility index and the Hausner ratio are calculated as follows:

$$Compressibility\ Index = 100 \times \frac{V_0 - V_f}{V_0}$$

$$Hausner\ Ratio = \frac{V_0}{V_f}$$

Alternatively, the compressibility index and Hausner ratio may be calculated using measured values of bulk density (ρ_{bulk}) and tapped density (ρ_{tapped}) as follows:

$$Compressibility\ Index = 100 \times \frac{\rho_{tapped} - \rho_{bulk}}{\rho_{tapped}}$$

$$Hausner\ Ratio = \frac{\rho_{tapped}}{\rho_{bulk}}$$

In a variation of these methods, the rate of consolidation is sometimes measured rather than, or in addition to, the change in volume that occurs on tapping. For the compressibility index and the Hausner ratio, the generally accepted scale of flowability is given in Table 2.9.36.-2.

Table 2.9.36.-2. – *Scale of flowability*[1]

Compressibility index (per cent)	Flow character	Hausner ratio
1-10	Excellent	1.00-1.11
11-15	Good	1.12-1.18
16-20	Fair	1.19-1.25
21-25	Passable	1.26-1.34
26-31	Poor	1.35-1.45
32-37	Very poor	1.46-1.59
> 38	Very, very poor	> 1.60

Experimental considerations for the compressibility index and Hausner ratio

Compressibility index and Hausner ratio are not intrinsic properties of the powder, that is to say, they are dependent upon the methodology used. The existing literature points out several important considerations affecting the determination of the unsettled apparent volume, V_0, of the final tapped volume, V_f, of the bulk density, ρ_{bulk}, and of the tapped density, ρ_{tapped}:

– the diameter of the cylinder used,
– the number of times the powder is tapped to achieve the tapped density,
– the mass of material used in the test,
– rotation of the sample during tapping.

Recommended procedure for compressibility index and Hausner ratio

Use a 250 ml volumetric cylinder with a test sample mass of 100 g. Smaller amounts and volumes may be used, but variations in the method must be described with the results. An average of 3 determinations is recommended.

FLOW THROUGH AN ORIFICE

The flow rate of a material depends upon many factors, some of which are particle-related and some related to the process. Monitoring the rate of flow of material through an orifice has been proposed as a better measure of powder flowability. Of particular significance is the utility of monitoring flow continuously, since pulsating flow patterns have been observed even for free-flowing materials. Changes in flow

rate as the container empties can also be observed. Empirical equations relating flow rate to the diameter of the opening, particle size, and particle density have been determined. However, determining the flow rate through an orifice is useful only with free-flowing materials.

The flow rate through an orifice is generally measured as the mass per time flowing from any of a number of types of containers (cylinders, funnels, hoppers). Measurement of the flow rate can be in discrete increments or continuous.

Basic methods for flow through an orifice

There are a variety of methods described in the literature. The most common for determining the flow rate through an orifice can be classified based on 3 important experimental variables:

- the type of container used to contain the powder. Common containers are cylinders, funnels, and hoppers from production equipment;
- the size and shape of the orifice used. The orifice diameter and shape are critical factors in determining powder flow rate;
- the method of measuring powder flow rate. Flow rate can be measured continuously using an electronic balance with some sort of recording device (strip chart recorder, computer). It can also be measured in discrete samples (for example, the time it takes for 100 g of powder to pass through the orifice to the nearest tenth of a second or the amount of powder passing through the orifice in 10 s to the nearest tenth of a gram).

Variations in methods for flow through an orifice

Either mass flow rate or volume flow rate can be determined. Mass flow rate is the easier of the methods, but it biases the results in favour of high-density materials. Since die fill is volumetric, determining volume flow rate may be preferable. A vibrator is occasionally attached to facilitate flow from the container, however, this appears to complicate interpretation of results. A moving orifice device has been proposed to more closely simulate rotary press conditions. The minimum diameter orifice through which powder flows can also be identified.

General scale of flowability for flow through an orifice

No general scale is available because flow rate is critically dependent on the method used to measure it. Comparison between published results is difficult.

Experimental considerations for flow through an orifice

Flow rate through an orifice is not an intrinsic property of the powder. It is very much dependent upon the methodology used. The existing literature points out several important considerations affecting these methods:

- the diameter and shape of the orifice,
- the type of container material (metal, glass, plastic),
- the diameter and height of the powder bed.

Recommended procedure for flow through an orifice

Flow rate through an orifice can be used only for materials that have some capacity to flow. It is not useful for cohesive materials. Provided that the height of the powder bed (the 'head' of powder) is much greater than the diameter of the orifice, the flow rate is virtually independent of the powder head. It is advisable to use a cylinder as the container, because the walls of the container must have little effect on flow. This configuration results in flow rate being determined by the movement of powder over powder, rather than powder along the wall of the container. Powder flow rate often increases when the height of the powder column is less than twice the diameter of the column. The orifice must be circular and the cylinder must be free of vibration. General guidelines for dimensions of the cylinder are as follows:

- diameter of the opening greater than 6 times the diameter of the particles,
- diameter of the cylinder greater than twice the diameter of the opening.

Use of a hopper as the container may be appropriate and representative of flow in a production situation. It is not advisable to use a funnel, particularly one with a stem, because flow rate will be determined by the size and length of the stem as well as the friction between the stem and the powder. A truncated cone may be appropriate, but flow will be influenced by the powder-wall friction coefficient, thus, selection of an appropriate construction material is important.

For the opening in the cylinder, use a flat-faced bottom plate with the option to vary orifice diameter to provide maximum flexibility and better ensure a powder-over-powder flow pattern. Rate measurement can be either discrete or continuous. Continuous measurement using an electronic balance can more effectively detect momentary flow rate variations.

SHEAR CELL METHODS

In an effort to put powder flow studies and hopper design on a more fundamental basis, a variety of powder shear testers and methods that permit more thorough and precisely defined assessment of powder flow properties have been developed. Shear cell methodology has been used extensively in the study of pharmaceutical materials. From these methods, a wide variety of parameters can be obtained, including the yield loci representing the shear stress-shear strain relationship, the angle of internal friction, the unconfined yield strength, the tensile strength, and a variety of derived parameters such as the flow factor and other flowability indices. Because of the ability to control experimental parameters more precisely, flow properties can also be determined as a function of consolidation load, time, and other environmental conditions. These methods have been successfully used to determine critical hopper and bin parameters.

Basic methods for shear cell

One type of shear cell is the cylindrical shear cell which is split horizontally, forming a shear plane between the lower stationary base and the upper moveable portion of the shear cell ring. After powder bed consolidation in the shear cell (using a well-defined procedure), the force necessary to shear the powder bed by moving the upper ring is determined. Annular shear cell designs offer some advantages over the cylindrical shear cell design, including the need for less material. A disadvantage, however, is that because of its design, the powder bed is not sheared as uniformly because material on the outside of the annulus is sheared more than material in the inner region. A third type of shear cell (plate-type) consists of a thin sandwich of powder between a lower stationary rough surface and an upper rough surface that is moveable.

All of the shear cell methods have their advantages and disadvantages, but a detailed review is beyond the scope of this chapter. As with the other methods for characterising powder flow, many variations are described in the literature. A significant advantage of shear cell methodology in general is a greater degree of experimental control. The methodology generally is rather time-consuming and requires significant amounts of material and a well-trained operator.

Recommendations for shear cell

The many existing shear cell configurations and test methods provide a wealth of data and can be used very effectively to characterise powder flow. They are also helpful in the design of equipment such as hoppers and bins. Because of the diversity of available equipment and experimental procedures, no specific recommendations regarding methodology are presented in this chapter. It is recommended that the results of powder flow characterisation using shear cell methodology include a complete description of equipment and methodology used.

2.9.37. OPTICAL MICROSCOPY

Optical microscopy for particle characterisation can generally be applied to particles of 1 µm and greater. The lower limit is imposed by the resolving power of the microscope. The upper limit is less definite and is determined by the increased difficulty associated with the characterisation of larger particles. Various alternative techniques are available for particle characterisation outside the applicable range of optical microscopy. Optical microscopy is particularly useful for characterising particles that are not spherical. This method may also serve as a base for the calibration of faster and more routine methods that may be developed.

Apparatus. Use a microscope that is stable and protected from vibration. The microscope magnification (product of the objective magnification, ocular magnification, and additional magnifying components) must be sufficient to allow adequate characterisation of the smallest particles to be classified in the test sample. The greatest numerical aperture of the objective is sought for each magnification range. Polarising filters may be used in conjunction with suitable analysers and retardation plates. Colour filters of relatively narrow spectral transmission are used with achromatic objectives, and are preferable with apochromats; they are required for appropriate colour rendition in photomicrography. Condensers, corrected at least for spherical aberration are used in the microscope substage and with the lamp. The numerical aperture of the substage condenser matches that of the objective under the conditions of use; this is affected by the actual aperture of the condenser diaphragm and the presence of immersion oils.

Adjustment. The precise alignment of all elements of the optical system and proper focusing are essential. The focusing of the elements is done in accordance with the recommendations of the microscope manufacturer. Critical axial alignment is recommended.

Illumination. A requirement for good illumination is a uniform and adjustable intensity of light over the entire field of view; Köhler illumination is preferred. With coloured particles, choose the colour of the filters so as to control the contrast and detail of the image.

Visual characterisation. The magnification and numerical aperture must be sufficiently high to allow adequate resolution of the images of the particles to be characterised. Determine the actual magnification using a calibrated stage micrometer to calibrate an ocular micrometer. Errors can be minimised if the magnification is sufficient that the image of the particle is at least 10 ocular divisions. Each objective must be calibrated separately. To calibrate the ocular scale, the stage micrometer scale and the ocular scale must be aligned. In this way, a precise determination of the distance between ocular stage divisions can be made. Several different magnifications may be necessary to characterise materials having a wide particle size distribution.

Photographic characterisation. If particle size is to be determined by photographic methods, take care to ensure that the object is sharply focused at the plane of the photographic emulsion. Determine the actual magnification by photographing a calibrated stage micrometer, using photographic film of sufficient speed, resolving power, and contrast. Exposure and processing must be identical for photographs of both the test sample and the determination of magnification. The apparent size of a photographic image is influenced by the exposure, development, and printing processes as well as by the resolving power of the microscope.

Preparation of the mount. The mounting medium will vary according to the physical properties of the test sample. Sufficient, but not excessive, contrast between the sample and the mounting medium is required to ensure adequate detail of the sample edge. The particles must rest in one plane and be adequately dispersed to distinguish individual particles of interest. Furthermore, the particles must be representative of the distribution of sizes in the material and must not be altered during preparation of the mount. Care must be taken to ensure that this important requirement is met. Selection of the mounting medium must include a consideration of the analyte solubility.

Crystallinity characterisation. The crystallinity of a material may be characterised to determine compliance with the crystallinity requirement where stated in the individual monograph of a drug substance. Unless otherwise specified in the individual monograph, mount a few particles of the sample in mineral oil on a clean glass slide. Examine the mixture using a polarising microscope: the particles show birefringence (interference colors) and extinction positions when the microscope stage is revolved.

Limit test of particle size by microscopy. Weigh a suitable quantity of the powder to be examined (for example, 10-100 mg), and suspend it in 10 ml of a suitable medium in which the powder does not dissolve, adding, if necessary, a wetting agent. A homogeneous suspension of particles can be maintained by suspending the particles in a medium of similar or matching density and by providing adequate agitation. Introduce a portion of the homogeneous suspension into a suitable counting cell, and scan under a microscope an area corresponding to not less than 10 µg of the powder to be examined. Count all the particles having a maximum dimension greater than the prescribed size limit. The size limit and the permitted number of particles exceeding the limit are defined for each substance.

Particle size characterisation. The measurement of particle size varies in complexity depending on the shape of the particle, and the number of particles characterised must be sufficient to ensure an acceptable level of uncertainty in the measured parameters. Additional information on particle size measurement, sample size, and data analysis is available, for example, in ISO 9276. For spherical particles, size is defined by the diameter. For irregular particles, a variety of definitions of particle size exist. In general, for irregularly shaped particles, characterisation of particle size must also include information on the type of diameter measured as well as information on particle shape. Several commonly used measurements of particle size are defined in Figure 2.9.37.-1.

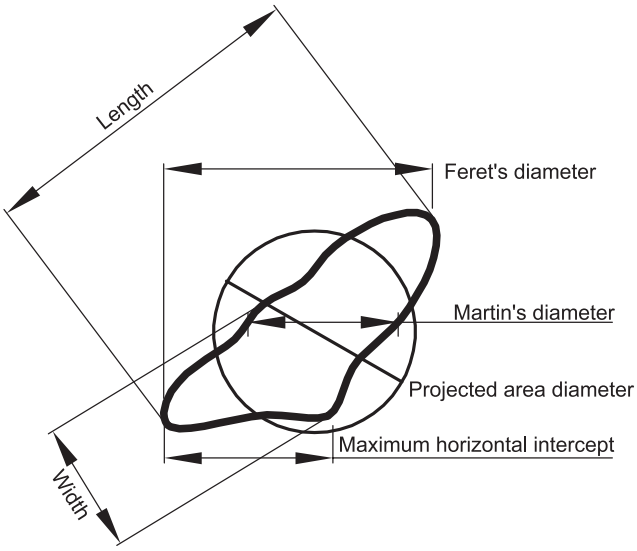

Figure 2.9.37.-1. – *Commonly used measurements of particle size*

– *Feret's diameter*: the distance between imaginary parallel lines tangent to a randomly oriented particle and perpendicular to the ocular scale,

– *Martin's diameter*: the diameter of the particle at the point that divides a randomly oriented particle into 2 equal projected areas,

– *projected area diameter*: the diameter of a circle that has the same projected area as the particle,

– *length*: the longest dimension from edge to edge of a particle oriented parallel to the ocular scale,

– *width*: the longest dimension of the particle measured at right angles to the length.

Particle shape characterisation. For irregularly shaped particles, characterisation of particle size must also include information on particle shape. The homogeneity of the powder must be checked using appropriate magnification. The following defines some commonly used descriptors of particle shape (see Figure 2.9.37.-2).

– *acicular*: slender, needle-like particle of similar width and thickness,

– *columnar*: long, thin particle with a width and thickness that are greater than those of an acicular particle,

– *flake*: thin, flat particle of similar length and width,

– *plate*: flat particle of similar length and width but with greater thickness than a flake particle,

– *lath*: long, thin, blade-like particle,

– *equant*: particle of similar length, width, and thickness; both cubical and spherical particles are included.

General observations. A particle is generally considered to be the smallest discrete unit. A particle may be a liquid or semi-solid droplet; a single crystal or polycrystalline; amorphous or an agglomerate. Particles may be associated. This degree of association may be described by the following terms:

– *lamellar*: stacked plates,

– *aggregate*: mass of adhered particles,

– *agglomerate*: fused or cemented particles,

– *conglomerate*: mixture of 2 or more types of particles,

– *spherulite*: radial cluster,

– *drusy*: particle covered with tiny particles.

Particle condition may be described by the following terms:

– *edges*: angular, rounded, smooth, sharp, fractured,

– *optical*: color (using proper color balancing filters), transparent, translucent, opaque,

– *defects*: occlusions, inclusions.

Surface characteristics may be described as:

– *cracked*: partial split, break, or fissure,

– *smooth*: free of irregularities, roughness, or projections,

– *porous*: having openings or passageways,

– *rough*: bumpy, uneven, not smooth,

– *pitted*: small indentations.

01/2008:20938

2.9.38. PARTICLE-SIZE DISTRIBUTION ESTIMATION BY ANALYTICAL SIEVING

Sieving is one of the oldest methods of classifying powders and granules by particle-size distribution. When using a woven sieve cloth, the sieving will essentially sort the particles by their intermediate size dimension (i.e., breadth or width). Mechanical sieving is most suitable where the majority of the particles are larger than about 75 µm. For smaller particles, their light weight provides insufficient force during sieving to overcome the surface forces of cohesion and adhesion that cause the particles to stick to each other and to the sieve, and thus cause particles that would be expected to pass through the sieve to be retained. For such materials other means of agitation such as air-jet sieving or sonic sifting may be more appropriate. Nevertheless, sieving can sometimes be used for some powders or granules having median particle sizes smaller than 75 µm where the method can be validated. In pharmaceutical terms, sieving is usually the method of choice for classification of the coarser grades of single powders or granules. It is a particularly attractive method in that powders and granules are classified only on the basis of particle size, and in most cases the analysis can be carried out in the dry state.

Among the limitations of the sieving method are the need for an appreciable amount of sample (normally at least 25 g, depending on the density of the powder or granule, and the diameter of the test sieves) and difficulty in sieving oily or other cohesive powders or granules that tend to clog the sieve openings. The method is essentially a two-dimensional estimate of size because passage through the sieve aperture is frequently more dependent on maximum width and thickness than on length.

This method is intended for estimation of the total particle-size distribution of a single material. It is not intended for determination of the proportion of particles passing or retained on 1 or 2 sieves.

Estimate the particle-size distribution as described under Dry sieving method, unless otherwise specified in the individual monograph. Where difficulty is experienced in reaching the endpoint (i.e., material does not readily pass through the sieves) or when it is necessary to use the finer end of the sieving range (below 75 µm), serious consideration must be given to the use of an alternative particle-sizing method.

Sieving is carried out under conditions that do not cause the test sample to gain or lose moisture. The relative humidity of the environment in which the sieving is carried out must be controlled to prevent moisture uptake or loss by the sample. In the absence of evidence to the contrary, analytical test sieving is normally carried out at ambient humidity. Any special conditions that apply to a particular material must be detailed in the individual monograph.

Principles of analytical sieving. Analytical test sieves are constructed from a woven-wire mesh, which is of simple weave that is assumed to give nearly square apertures and is sealed into the base of an open cylindrical container. The basic analytical method involves stacking the sieves on top of one another in ascending degrees of coarseness, and then placing the test powder on the top sieve. The nest of sieves is subjected to a standardised period of agitation, and then the weight of material retained on each sieve is accurately determined. The test gives the weight percentage of powder in each sieve size range.

This sieving process for estimating the particle-size distribution of a single pharmaceutical powder is generally intended for use where at least 80 per cent of the particles are larger than 75 µm. The size parameter involved in determining particle-size distribution by analytical sieving is the length of the side of the minimum square aperture through which the particle will pass.

TEST SIEVES

Test sieves suitable for pharmacopoeial tests conform to the most current edition of *ISO 3310-1: Test sieves – Technical requirements and testing - Part 1: Test sieves of metal wire cloth* (see Table 2.9.38.-1). Unless otherwise specified in the monograph, use those ISO sieves listed as principal sizes in Table 2.9.38.-1 that are recommended in the particular region.

Sieves are selected to cover the entire range of particle sizes present in the test sample. A nest of sieves having a $\sqrt{2}$ progression of the area of the sieve openings is recommended. The nest of sieves is assembled with the coarsest screen at the top and the finest at the bottom. Use micrometres or millimetres in denoting test sieve openings (Note: mesh numbers are provided in the table for conversion purposes only).

Test sieves are made from stainless steel or, less preferably, from brass or other suitable non-reactive wire.

Calibration and recalibration of test sieves is in accordance with the most current edition of ISO 3310-1. Sieves are carefully examined for gross distortions and fractures, especially at their screen frame joints, before use. Sieves may be calibrated optically to estimate the average opening size, and opening variability, of the sieve mesh. Alternatively, for the evaluation of the effective opening of test sieves in the size range of 212-850 µm, standard glass spheres are available. Unless otherwise specified in the individual monograph, perform the sieve analysis at controlled room temperature and at ambient relative humidity.

Cleaning test sieves. Ideally, test sieves are cleaned using only a low-pressure air jet or a liquid stream. If some apertures remain blocked by test particles, careful gentle brushing may be used as a last resort.

Test sample. If the test sample mass is not given in the monograph for a particular material, use a test sample having a mass between 25-100 g, depending on the bulk density of the material, for test sieves having a 200 mm diameter. For 76 mm sieves, the amount of material that can be accommodated is approximately 1/7 that which can be accommodated by a 200 mm sieve. Determine the most appropriate mass for a given material by test sieving accurately weighed samples of different masses, such as 25 g, 50 g, and 100 g, for the same time period on a mechanical shaker (note: if the test results are similar for the 25 g and 50 g samples, but the 100 g sample shows a lower percentage through the finest sieve, the 100 g sample size is too large). Where only a sample of 10-25 g is available, smaller diameter test sieves conforming to the same mesh specifications may be substituted, but the endpoint must be redetermined. The use of tests samples having a smaller mass (e.g. down to 5 g) may be needed. For materials with low apparent particle density, or for materials mainly comprising particles with a highly iso-diametrical shape, sample masses below 5 g for a 200 mm screen may be necessary to avoid excessive blocking of the sieve. During validation of a particular sieve analysis method, it is expected that the problem of sieve blocking will have been addressed.

If the test material is prone to absorbing or losing significant amounts of water with varying humidity, the test must be carried out in an appropriately controlled environment. Similarly, if the test material is known to develop an electrostatic charge, careful observation must be made to ensure that such charging does not influence the analysis. An antistatic agent, such as colloidal silicon dioxide and/or aluminum oxide, may be added at a 0.5 per cent (*m/m*) level to minimise this effect. If both of the above effects cannot be eliminated, an alternative particle-sizing technique must be selected.

Agitation methods. Several different sieve and powder-agitation devices are commercially available, all of which may be used to perform sieve analyses. However, the different methods of agitation may give different results for sieve analyses and endpoint determinations because of the different types and magnitudes of the forces acting on the individual particles under test. Methods using mechanical agitation or electromagnetic agitation, and that can induce either a vertical oscillation or a horizontal circular motion, or tapping or a combination of both tapping and horizontal circular motion are available. Entrainment of the particles in an air stream may also be used. The results must indicate which agitation method was used and the agitation parameters used (if they can be varied), since changes in the agitation conditions will give different results for the sieve analysis and endpoint determination, and may be sufficiently different to give a failing result under some circumstances.

Endpoint determination. The test sieving analysis is complete when the mass on any of the test sieves does not change by more than 5 per cent or 0.1 g (10 per cent in the case of 76 mm sieves) of the previous mass on that sieve. If less than 5 per cent of the total sample mass is present on a given sieve, the endpoint for that sieve is increased to a mass change of not more than 20 per cent of the previous mass on that sieve.

If more than 50 per cent of the total sample mass is found on any one sieve, unless this is indicated in the monograph, the test is repeated, but with the addition to the sieve nest of a more coarse sieve intermediate between that carrying the excessive mass and the next coarsest sieve in the original nest i.e., addition of the ISO series sieve omitted from the nest of sieves.

SIEVING METHODS

Mechanical agitation (Dry sieving method). Tare each test sieve to the nearest 0.1 g. Place an accurately weighed quantity of test sample on the top (coarsest) sieve, and replace the lid. Agitate the nest of sieves for 5 min, then carefully remove each sieve from the nest without loss of material. Reweigh each sieve, and determine the mass of material on each one. Determine the mass of material in the collecting pan in a similar manner. Re-assemble the nest of sieves, and agitate for 5 min. Remove and weigh each sieve as previously described. Repeat these steps until the endpoint criteria are met (see Endpoint determination under Test sieves). Upon completion of the analysis, reconcile the masses of material. Total losses must not exceed 5 per cent of the mass of the original test sample.

Repeat the analysis with a fresh sample, but using a single sieving time equal to that of the combined times used above. Confirm that this sieving time conforms to the requirements for endpoint determination. When this endpoint has been validated for a specific material, then a single fixed time of sieving may be used for future analyses, providing the particle size distribution falls within normal variation.

If there is evidence that the particles retained on any sieve are aggregates rather than single particles, the use of mechanical dry sieving is unlikely to give good reproducibility, and a different particle size analysis method must be used.

Air-entrainment methods (Air-jet and sonic-sifter sieving). Different types of commercial equipment that use a moving air current are available for sieving. A system that uses a single sieve at a time is referred to as, air-jet, sieving. It uses the same general sieving methodology as that described under Dry sieving method, but with a standardised air jet replacing the normal agitation mechanism. It requires sequential analyses on individual sieves starting with the finest sieve to obtain a particle size distribution. Air jet sieving often includes the use of finer test sieves than used in ordinary dry sieving. This technique is more suitable where only oversize or undersize fractions are needed.

In the sonic sifting method, a nest of sieves is used, and the test sample is carried in a vertically oscillating column of air that lifts the sample and then carries it back against the mesh openings at a given number of pulses per minute. It may be necessary to lower the sample amount to 5 g, when sonic sifting is employed.

The air-jet sieving and sonic sieving methods may be useful for powders or granules when the mechanical sieving techniques are incapable of giving a meaningful analysis.

These methods are highly dependent upon proper dispersion of the powder in the air current. This requirement may be hard to achieve if the method is used at the lower end of the sieving range (i.e., below 75 μm), when the particles tend to be more cohesive, and especially if there is any tendency for the material to develop an electrostatic charge. For the above reasons endpoint determination is particularly critical, and it is very important to confirm that the oversize material comprises single particles and is not composed of aggregates.

INTERPRETATION

The raw data must include the mass of test sample, the total sieving time, the precise sieving methodology, and the set values for any variable parameters, in addition to the masses retained on the individual sieves and in the pan.

It may be convenient to convert the raw data into a cumulative mass distribution, and if it is desired to express the distribution in terms of a cumulative mass undersize, the range of sieves used must include a sieve through which all the material passes. If there is evidence on any of the test sieves that the material remaining on it is composed of aggregates formed during the sieving process, the analysis is invalid.

01/2008:20940

2.9.40. UNIFORMITY OF DOSAGE UNITS

To ensure the consistency of dosage units, each unit in a batch should have an active substance content within a narrow range around the label claim. Dosage units are defined as dosage forms containing a single dose or a part of a dose of an active substance in each dosage unit. The uniformity of dosage units specification is not intended to apply to suspensions, emulsions, or gels in single-dose containers intended for cutaneous administration.

The term “Uniformity of dosage unit” is defined as the degree of uniformity in the amount of the active substance among dosage units. Therefore, the requirements of this chapter apply to each active substance being comprised in dosage units containing one or more active substances, unless otherwise specified elsewere in this Pharmacopoeia.

The uniformity of dosage units can be demonstrated by either of 2 methods: content uniformity or mass variation (see Table 2.9.40.-1).

The test for content uniformity of preparations presented in dosage units is based on the assay of the individual contents of active substance(s) of a number of dosage units to determine whether the individual contents are within the limits set. The content uniformity method may be applied in all cases.

The test for mass variation is applicable for the following dosage forms:

(1) solutions enclosed in single-dose containers and in soft capsules;

(2) solids (including powders, granules and sterile solids) that are packaged in single-dose containers and contain no active or inactive added substances;

(3) solids (including sterile solids) that are packaged in single-dose containers, with or without active or inactive added substances, that have been prepared from true solutions and freeze-dried in the final containers and are labelled to indicate this method of preparation;

(4) hard capsules, uncoated tablets, or film-coated tablets, containing 25 mg or more of an active substance comprising 25 per cent or more, by mass, of the dosage unit or, in the case of hard capsules, the capsule contents, except that uniformity of other active substances present in lesser proportions is demonstrated by meeting content uniformity requirements.

Table 2.9.40.-1. – *Application of Content Unformity (CU) and Mass Variation (MV) test for dosage forms*

Dosage forms	Type	Sub-Type	Dose and ratio of active substance	
			≥ 25 mg and ≥ 25 per cent	< 25 mg or < 25 per cent
Tablets	uncoated		MV	CU
	coated	film-coated	MV	CU
		others	CU	CU
Capsules	hard		MV	CU
	soft	suspensions, emulsions, gels	CU	CU
		solutions	MV	MV
Solids in single-dose containers	single component		MV	MV
	multiple components	solution freeze-dried in final container	MV	MV
		others	CU	CU
Solutions enclosed in single-dose containers			MV	MV
Others			CU	CU

The test for content uniformity is required for all dosage forms not meeting the above conditions for the mass variation test. Alternatively, products that do not meet the 25 mg/25 per cent threshold limit may be tested for uniformity of dosage units by mass variation instead of the content uniformity test on the following condition: the concentration Relative Standard Deviation (RSD) of the active substance in the final dosage units is not more than 2 per cent, based on process validation data and development data, and if there has been regulatory approval of such a change. The concentration RSD is the RSD of the concentration per dosage unit (*m/m* or *m/V*), where concentration per dosage unit equals the assay result per dosage unit divided by the individual dosage unit mass. See the RSD formula in Table 2.9.40.-2.

CONTENT UNIFORMITY

Select not less than 30 units, and proceed as follows for the dosage form designated. Where different procedures are used for assay of the preparation and for the content uniformity test, it may be necessary to establish a correction factor to be applied to the results of the latter.

Solid dosage forms. Assay 10 units individually using an appropriate analytical method. Calculate the acceptance value (see Table 2.9.40.-2).

Liquid dosage forms. Assay 10 units individually using an appropriate analytical method. Carry out the assay on the amount of well-mixed material that is removed from an individual container in conditions of normal use. Express the results as delivered dose. Calculate the acceptance value (see Table 2.9.40.-2).

Calculation of Acceptance Value

Calculate the Acceptance Value (*AV*) using the formula:

$$\left|M - \overline{X}\right| + ks$$

in which the terms are as defined in Table 2.9.40.-2.

MASS VARIATION

Carry out an assay for the active substance(s) on a representative sample of the batch using an appropriate analytical method. This value is result *A*, expressed as percentage of label claim (see Calculation of Acceptance Value). Assume that the concentration (mass of active substance per mass of dosage unit) is uniform. Select not less than 30 dosage units, and proceed as follows for the dosage form designated.

Uncoated or film-coated tablets. Accurately weigh 10 tablets individually. Calculate the active substance content, expressed as percentage of label claim, of each tablet from the mass of the individual tablets and the result of the assay. Calculate the acceptance value.

Hard capsules. Accurately weigh 10 capsules individually, taking care to preserve the identity of each capsule. Remove the contents of each capsule by suitable means. Accurately weigh the emptied shells individually, and calculate for each capsule the net mass of its contents by subtracting the mass of the shell from the respective gross mass. Calculate the active substance content in each capsule from the mass of product removed from the individual capsules and the result of the assay. Calculate the acceptance value.

Soft capsules. Accurately weigh 10 intact capsules individually to obtain their gross masses, taking care to preserve the identity of each capsule. Then cut open the capsules by means of a suitable clean, dry cutting instrument such as scissors or a sharp open blade, and remove the contents by washing with a suitable solvent. Allow the occluded solvent to evaporate from the shells at room temperature over a period of about 30 min, taking precautions to avoid uptake or loss of moisture. Weigh the individual shells, and calculate the net contents. Calculate the active substance content on each capsule from the mass of product removed from the individual capsules and the result of the assay. Calculate the acceptance value.

Solid dosage forms other than tablets and capsules. Proceed as directed for hard capsules, treating each unit as described therein. Calculate the acceptance value.

Liquid dosage forms. Accurately weigh the amount of liquid that is removed from each of 10 individual containers in conditions of normal use. If necessary, compute the equivalent volume after determining the density. Calculate the active substance content in each container from the mass of product removed from the individual containers and the result of the assay. Calculate the acceptance value.

Table 2.9.40.-2.

Variable	Definition	Conditions	Value
$\overline{X}$	Mean of individual contents (x_1, x_2,..., x_n), expressed as a percentage of the label claim		
x_1, x_2,..., x_n	Individual contents of the dosage units tested, expressed as a percentage of the label claim		
n	Sample size (number of dosage units in a sample)		
k	Acceptability constant	If n = 10, then	2.4
		If n = 30, then	2.0
s	Sample standard deviation		$\left[\frac{\sum_{i=1}^{n}(x_i-\overline{X})^2}{n-1}\right]^{1/2}$
RSD	Relative standard deviation (the sample standard deviation expressed as a percentage of the mean)		$\frac{100s}{\overline{X}}$
M (case 1) To be applied when $T \leq 101.5$	Reference value	If 98.5 per cent ≤ $\overline{X}$ ≤ 101.5 per cent, then	$M = \overline{X}$ ($AV = ks$)
		If $\overline{X}$ < 98.5 per cent, then	M = 98.5 per cent ($AV = 98.5 - \overline{X} + ks$)
		If $\overline{X}$ > 101.5 per cent, then	M = 101.5 per cent ($AV = \overline{X} - 101.5 + ks$)
M (case 2) To be applied when $T > 101.5$	Reference value	If 98.5 per cent ≤ $\overline{X} \leq T$, then	$M = \overline{X}$ ($AV = ks$)
		If $\overline{X}$ < 98.5 per cent, then	M = 98.5 per cent ($AV = 98.5 - \overline{X} + ks$)
		If $\overline{X} > T$, then	$M = T$ per cent ($AV = \overline{X} - T + ks$)
Acceptance value (AV)			General formula: $\lvert M - \overline{X} \rvert + ks$ Calculations are specified above for the different cases.
$L1$	Maximum allowed acceptance value		$L1$ = 15.0 unless otherwise specified
$L2$	Maximum allowed range for deviation of each dosage unit tested from the calculated value of M	On the low side, no dosage unit result can be less than 0.75 M while on the high side, no dosage unit result can be greater than 1.25 M (This is based on $L2$ value of 25.0)	$L2$ = 25.0 unless otherwise specified
T	Target test sample amount at time of manufacture		

Calculation of Acceptance Value. Calculate the acceptance value (AV) as shown in content uniformity, except that the individual contents of the units are replaced with the individual estimated contents defined below.

x_1, x_2,..., x_n = individual estimated contents of the dosage units tested,

where

$$x_i = w_i \times \frac{A}{\overline{W}}$$

w_1, w_2,..., w_n = individual masses of the dosage units tested,

A = content of active substance (percentage of label claim) obtained using an appropriate analytical method,

$\overline{W}$ = mean of individual masses (w_1, w_2,..., w_n).

CRITERIA

Apply the following criteria, unless otherwise specified.

Solid and liquid dosage forms. The requirements for dosage uniformity are met if the acceptance value of the first 10 dosage units is less than or equal to $L1$. If the acceptance value is greater than $L1$, test the next 20 dosage units and calculate the acceptance value. The requirements are met if the final acceptance value of the 30 dosage units is less than or equal to $L1$ and no individual content of the dosage unit is less than $(1 - L2 \times 0.01)M$ nor more than $(1 + L2 \times 0.01)M$ in calculation of acceptance value under content uniformity or under mass variation. Unless otherwise specified, $L1$ is 15.0 and $L2$ is 25.0.

01/2008:20941

2.9.41. FRIABILITY OF GRANULES AND SPHEROIDS

This chapter describes 2 methods for determination of the friability of granules and spheroids, which may be used during development studies. It is recognised, however, that many methods with equal suitability may be used.

This test is intended to determine, under defined conditions, the friability of granules and spheroids. Friability is defined as a reduction in the mass of the granules or spheroids or in the formation of fragments of granules or spheroids, occurring when the granules or spheroids are subjected to mechanical strain during handling (tumbling, vibration, fluidisation, etc.). Examples of changes are abrasion, breakage or deformation of granules or spheroids.

METHOD A

Apparatus (fluidised-bed apparatus). The apparatus (see Figure 2.9.41.-1) consists of a glass cylinder (A) with a conical lower part. The cylinder is provided with a sieve lid (B) having an aperture size of 500 µm or any other suitable sieve. The conical end is connected to a U-shaped glass tube (C) that can be disconnected from the cylinder for removal of the granules or spheroids. The U-tube is attached to a T-coupling (D). One inlet of the T-coupling is joined by a silicone tube to a manometer for regulating the compressed-air flow (use compressed air complying with the test for water in the monograph *Medicinal air (1238)*), the other one is connected via a silicone tube to a by-pass flowmeter (E) (0.10-1.00 $m^3 \cdot h^{-1}$).

Procedure. *The following procedure is usually suitable.* Remove the fine particles by sieving (sieve having an aperture size of 710 µm or any other suitable sieve). Introduce about 8.0 g (m_1) of granules or spheroids into the cylinder (A). Close the apparatus with the sieve lid (B). Adjust the flow rate of the compressed air to 0.45 $m^3 \cdot h^{-1}$. After 15 min, remove the granules or spheroids from the apparatus by disconnecting the U-tube and weigh again (m_2). Test 3 samples and calculate the mean value. It is recommended

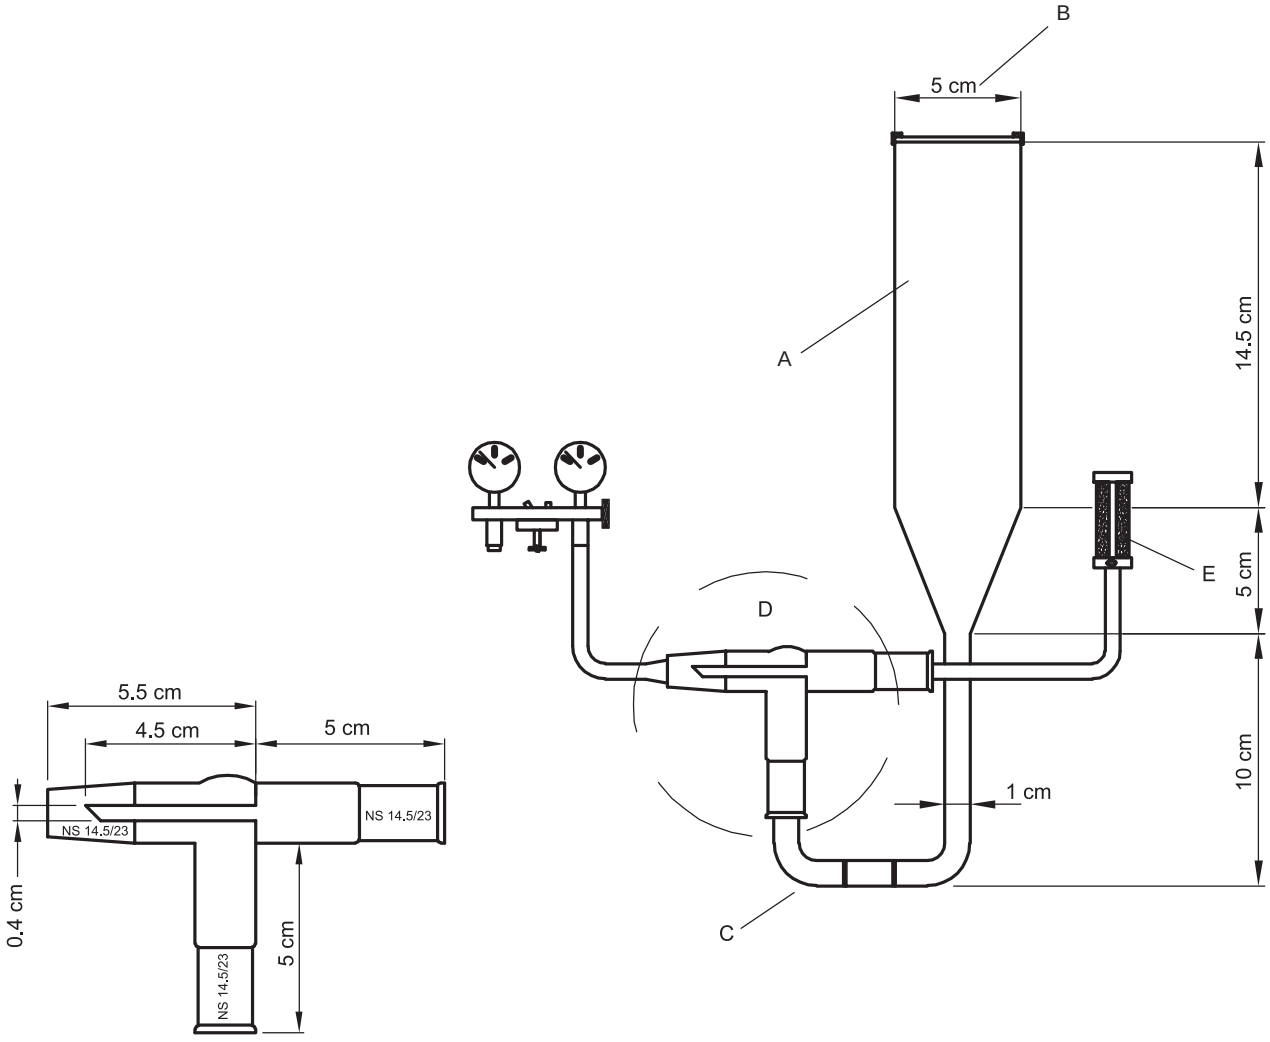

Figure 2.9.41.-1. – *Fluidised-bed apparatus*

to spray the inside of the apparatus with an antistatic agent every 3 determinations in order to prevent electrostatic charging.

Loss on drying. Dry in an oven at 105 °C, unless otherwise prescribed. Alternatively, other drying conditions as described in general method *2.2.32* may be used.

Calculation

$$F = \frac{m_1\,(100 - T_1) - m_2\,(100 - T_2)}{m_1} \times 100$$

F = friability;

T_1 = percentage loss on drying before the test (mean of 2 determinations);

T_2 = percentage loss on drying after the test (mean of 2 determinations);

m_1 = mass of the granules or spheroids before the test, in grams;

m_2 = mass of the granules or spheroids after the test, in grams.

METHOD B

Apparatus (oscillating apparatus). The apparatus (see Figure 2.9.41.-2) consists of a 105 ml glass container, containing the granules or spheroids to be examined, which is subjected to horizontal oscillations. The frequency and duration of the oscillations can be varied continuously. The frequency can be adjusted, using a scale, to a value in the range 0-400 oscillations/min. The duration can be set to a value in the range 0-9999 s.

Procedure. *The following procedure is usually suitable.* Remove the fine particles by sieving (sieve having an aperture size of 355 µm or any other suitable sieve). In the glass container, weigh about 10.00 g (m_1) of the granules or spheroids. Install the container in the apparatus. Shake for 240 s at the highest frequency for hard granules or spheroids, or for 120 s at a lower frequency (e.g. 140 oscillations/min) for soft granules or spheroids. Sieve (355 µm, or the same sieve as used previously) and weigh the granules or spheroids again (m_2). Test 3 samples and calculate the mean value.

Loss on drying. Dry in an oven at 105 °C, unless otherwise prescribed. Alternatively, other drying conditions as described in general method *2.2.32* may be used.

Calculation

$$F = \frac{m_1\,(100 - T_1) - m_2\,(100 - T_2)}{m_1} \times 100$$

F = friability;

T_1 = percentage loss on drying before the test (mean of 2 determinations);

T_2 = percentage loss on drying after the test (mean of 2 determinations);

m_1 = mass of the granules or spheroids before the test, in grams;

m_2 = mass of the granules or spheroids after the test, in grams.

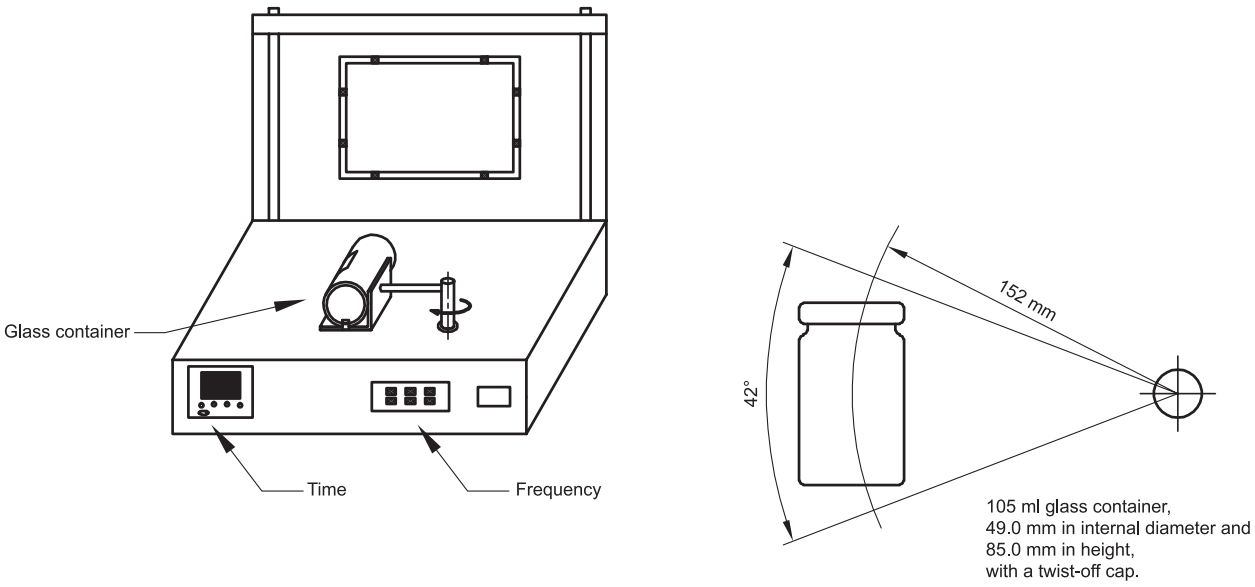

Figure 2.9.41.-2. – *Oscillating apparatus*

01/2008:20942

2.9.42. DISSOLUTION TEST FOR LIPOPHILIC SOLID DOSAGE FORMS

APPARATUS

The apparatus (see Figure 2.9.42.-1) consists of:

– A reservoir for the dissolution medium.

– A pump that forces the dissolution medium upwards through the flow-through cell.

– A flow-through cell shown in Figure 2.9.42.-2 specifically intended for lipophilic solid dosage forms such as suppositories and soft capsules. It consists of 3 transparent parts which fit into each other. The lower part (1) is made up of 2 adjacent chambers connected to an overflow device.

  The dissolution medium passes through chamber A and is subjected to an upwards flow. The flow in chamber B is downwards directed to a small-size bore exit which leads upwards to a filter assembly. The middle part (2) of the cell has a cavity designed to collect lipophilic excipients which float on the dissolution medium. A metal grill serves as a rough filter. The upper part (3) holds a filter unit for paper, glass fibre or cellulose filters.

– A water-bath that will maintain the dissolution medium at 37 ± 0.5 °C.

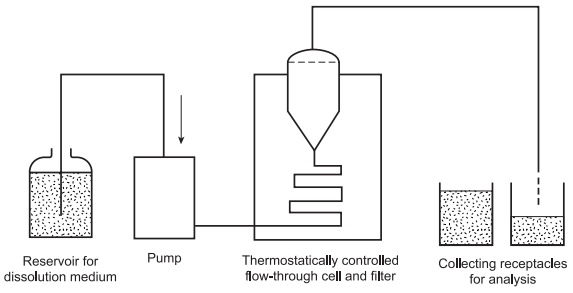

Figure 2.9.42.-1. – *Flow-through apparatus*

Dissolution medium. If the dissolution medium is buffered, adjust its pH to within ± 0.05 units of the prescribed value. Remove any dissolved gases from the dissolution medium before the test since they can cause the formation of bubbles that significantly affect the results.

METHOD

Place 1 unit of the preparation to be examined in chamber A. Close the cell with the prepared filter assembly. At the beginning of the test, chamber A requires air removal via a small orifice connected to the filter assembly. Heat the dissolution medium to an appropriate temperature taking the melting point of the preparation into consideration. Using a suitable pump, introduce the warmed dissolution medium through the bottom of the cell to obtain a suitable continuous flow through an open or closed circuit at the prescribed rate (± 5 per cent). When the dissolution medium reaches the overflow, air starts to escape through the capillary and chamber B fills with the dissolution medium. The preparation spreads through the dissolution medium according to its physico-chemical properties.

In justified and authorised cases, representative fractions of large volume suppositories may be tested.

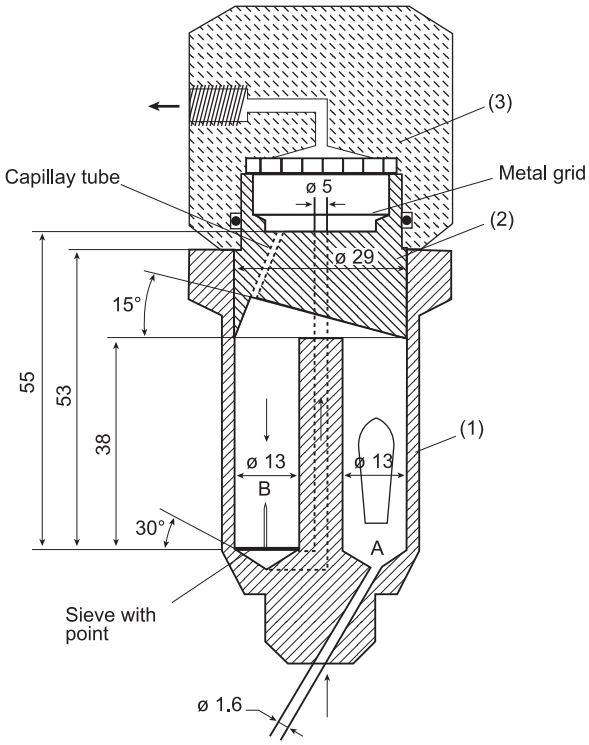

Figure 2.9.42.-2. – *Flow-through cell*
Dimensions in millimetres

SAMPLING AND EVALUATION

Samples are always collected at the outlet of the cell, irrespective of whether the circuit is opened or closed.

Filter the liquid removed using an inert filter of appropriate pore size that does not cause significant adsorption of the active substance from the solution and does not contain substances extractable by the dissolution medium that would interfere with the prescribed analytical method. Proceed with analysis of the filtrate as prescribed.

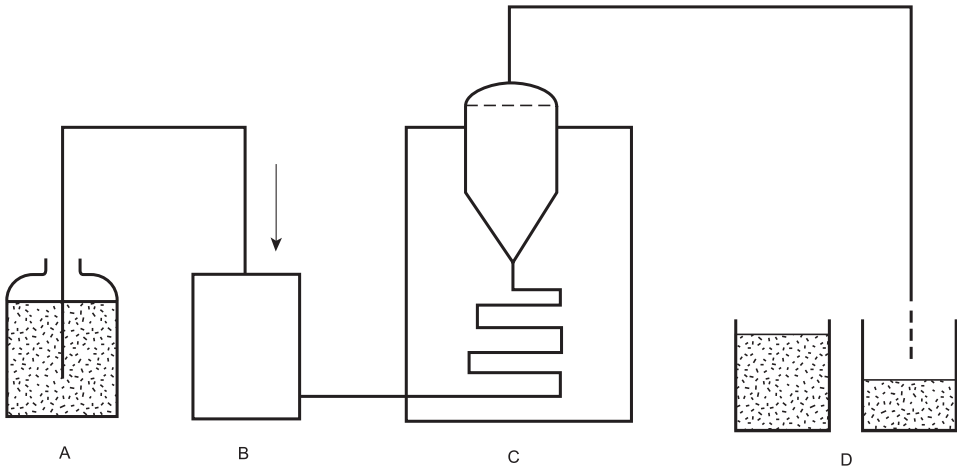
The quantity of the active substance dissolved in a specified time is expressed as a percentage of the content stated on the label.

01/2008:20943

2.9.43. APPARENT DISSOLUTION

This method is mainly used to determine the apparent dissolution rate of pure solid substances. It may also be used for the determination of the apparent dissolution rate of active substances in preparations presented as powders or granules.

APPARATUS



All parts of the apparatus that may come into contact with the sample or the dissolution medium are chemically inert and do not adsorb, react with, or interfere with the test sample. No part of the assembly or its environment contributes significant motion, agitation or vibration beyond that resulting from the flow-through system.

Apparatus that permits observation of the sample is preferable.

The apparatus (see Figure 2.9.43.-1) consists of:

– a reservoir for the dissolution medium;

– a pump that forces the dissolution medium upwards through the flow-through cell;

A. reservoir for dissolution medium B. pump C. thermostatically controlled flow-through cell and filter D. collecting vessels for analysis

Figure 2.9.43.-1. – *Flow-through apparatus*

– a flow-through cell, preferably of transparent material, mounted vertically with a filter system preventing escape of undissolved particles;
– a water-bath that will maintain the dissolution medium at the chosen temperature (generally 37 ± 0.5 °C).

The flow-through cell shown in Figure 2.9.43.-2 consists of 3 parts that fit into each other. The lower part supports a system of grids and filters on which the powder is placed. The middle part, which fits onto the lower part, contains an insert that sieves the sample when the dissolution medium flows through the cell. This insert is made up of 2 parts: a conical sieve that is placed on the sample and a clip placed midway down the middle part to hold the sieve in place when the dissolution medium passes through. A 2nd filtration assembly (grid and filter) is placed on top of the middle part before fitting the upper part through which the dissolution medium flows out of the cell.

DISSOLUTION MEDIUM

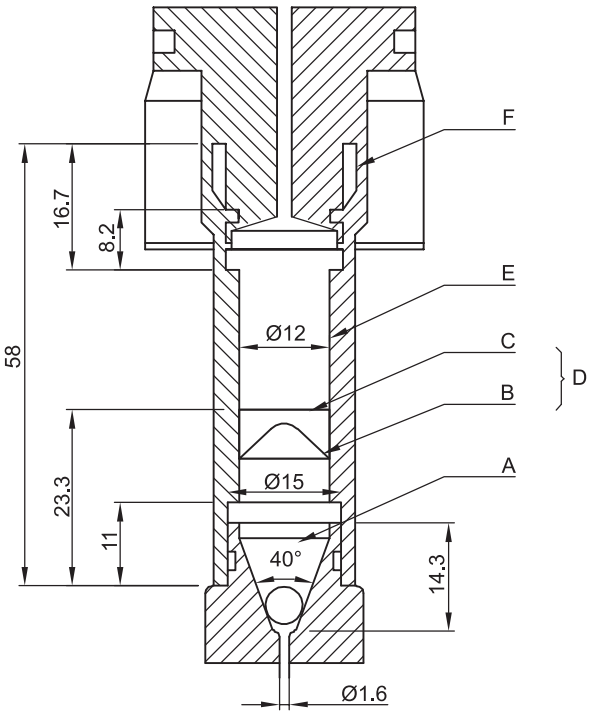
If the dissolution medium is buffered, adjust its pH to within ± 0.05 units. Remove any dissolved gases from the dissolution medium before the test, since they can cause the formation of bubbles, which significantly affect the results.

METHOD

Place a bead of 5 ± 0.5 mm diameter at the bottom of the cone of the lower part followed by glass beads of suitable size, preferably of 1 ± 0.1 mm diameter. Place a sieve (with 0.2 mm apertures), a suitable filter and a 2nd sieve on top of the lower part. Fit the middle part onto the lower part. Weigh the assembly. Place the sample on the filtration assembly and weigh the sample in the cell. Place the sieve of the insert, cone upwards, on the sample, and position the clip midway down the middle part. Place a sieve (with 0.2 mm apertures) and a suitable filter on top of the middle part. Fit the upper part. Heat the dissolution medium to the chosen temperature. Using a suitable pump, introduce the dissolution medium through the bottom of the cell to obtain a suitable continuous flow through an open or closed circuit at the prescribed rate ± 5 per cent.

SAMPLING

Samples of dissolution medium are collected at the outlet of the cell, irrespective of whether the circuit is opened or closed.



Immediately filter the liquid removed using an inert filter of appropriate pore size that does not cause significant adsorption of the substances from the solution and does not contain substances extractable by the dissolution medium that would interfere with the prescribed analytical method. Proceed with the analysis of the filtrate as prescribed.

ASSESSMENT OF THE RESULTS

When the test is performed for batch release purposes, an adequate number of replicates is carried out.

The results are expressed as:

– the amount of dissolved substance by time unit (if the dissolution is linear);
– the dissolution time of the whole sample and at appropriate intermediate stages.

A. lower part C. clip E. middle part
B. sieve D. insert F. upper part

Figure 2.9.43.-2. – *Flow-through cell*

3.1. MATERIALS USED FOR THE MANUFACTURE OF CONTAINERS

The materials described in this chapter are used for the manufacture of containers for pharmaceutical use. Their use may also be considered for the manufacture of part or all of objects used for medico-surgical purposes.

Materials and polymers other than those described in the Pharmacopoeia may be used subject to approval in each case by the competent authority responsible for the licensing for sale of the preparation in the container.

01/2008:30101

3.1.1. MATERIALS FOR CONTAINERS FOR HUMAN BLOOD AND BLOOD COMPONENTS

NOTE: for materials based on plasticised poly(vinyl chloride) for containers for aqueous solutions for intravenous infusion, see text 3.1.14.

Plastic containers for the collection, storage, processing and administration of blood and its components may be manufactured from one or more polymers, if necessary with certain additives.

If all or part of the container consists of a material described in a text of the Pharmacopoeia, the quality of the material is controlled by the methods indicated in that text. (See *3.1.1.1. Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components*).

In normal conditions of use the materials and containers made from such materials do not release monomers, or other substances, in amounts likely to be harmful nor do they lead to any abnormal modifications of the blood or blood components.

01/2008:90001
corrected 6.0

3.1.1.1. MATERIALS BASED ON PLASTICISED POLY(VINYL CHLORIDE) FOR CONTAINERS FOR HUMAN BLOOD AND BLOOD COMPONENTS

DEFINITION

Materials based on plasticised poly(vinyl chloride) contain not less than 55 per cent of poly(vinyl chloride) and contain various additives, in addition to the high-molecular-mass polymer obtained by polymerisation of vinyl chloride.

Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components are defined by the nature and the proportions of the substances used in their manufacture.

PRODUCTION

Materials based on plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test:

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (*2.2.28*), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject the remaining 25 ml of vinyl chloride slowly into the vial shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 hours. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into five of the vials. The six solutions thus obtained contain, respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamide R* and 5 per cent *m/m* of *macrogol 400 R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 45 °C, that of the injection port at 100 °C and that of the detector at 150 °C.

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

Additives

A certain number of additives are added to the polymers to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the following list which specifies for each product the maximum allowable content:

- not more than 40 per cent of di(2-ethylhexyl)phthalate (plastic additive 01),
- not more than 1 per cent of zinc octanoate (zinc 2-ethylhexanoate) (plastic additive 02),
- not more than 1 per cent of calcium stearate or zinc stearate or 1 per cent of a mixture of the two,
- not more than 1 per cent of *N,N'*-diacylethylenediamines (plastic additive 03),
- not more than 10 per cent of one of the following epoxidised oils or 10 per cent of a mixture of the two:
  - epoxidised soya oil (plastic additive 04), of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6,
  - epoxidised linseed oil (plastic additive 05), of which the oxiran oxygen content is not greater than 10 per cent and the iodine value is not greater than 7.

Very low amounts of antioxidants added to the vinyl chloride monomer may be detected in the polymer.

No antioxidant additive may be added to the polymer.

Ultramarine blue is the only colouring material permitted to be added.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Colourless or pale yellow powder, beads, granules or, after transformation, translucent sheets of varying thickness or containers, with a slight odour. On combustion it gives off dense, black smoke.

IDENTIFICATION

If necessary, before use, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

To 2.0 g of the material to be examined add 200 ml of *peroxide-free ether R* and heat under a reflux condenser for 8 h. Separate the residue B and the solution A by filtration.

Evaporate solution A to dryness under reduced pressure in a water-bath at 30 °C. Dissolve the residue in 10 ml of *toluene R* (solution A1). Dissolve the residue B in 60 ml of *ethylene chloride R*, heating on a water-bath under a reflux condenser. Filter. Add the solution dropwise and with vigorous shaking to 600 ml of *heptane R* heated almost to boiling. Separate the coagulum B1 and the organic solution by hot filtration. Allow the latter to cool; separate the precipitate B2 that forms and filter through a tared sintered-glass filter (40) (*2.1.2*).

A. Dissolve the coagulum B1 in 30 ml of *tetrahydrofuran R* and add, in small volumes with shaking, 40 ml of *ethanol R*. Separate the precipitate B3 by filtration and dry *in vacuo* at a temperature not exceeding 50 °C over *diphosphorus pentoxide R*. Dissolve a few milligrams of precipitate B3 in 1 ml of *tetrahydrofuran R*, place a few drops of the solution obtained on a sodium chloride plate and evaporate to dryness in an oven at 100 °C to 105 °C. Examine by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *poly(vinyl chloride) CRS*.

B. Examine the residue C obtained in the test for plastic additives 01, 04 and 05 by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *plastic additive 01 CRS*.

TESTS

If necessary, before use, cut samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 5.0 g of the material to be examined in a combustion flask. Add 30 ml of *sulphuric acid R* and heat until a black, syrupy mass is obtained. Cool and add carefully 10 ml of *strong hydrogen peroxide solution R*. Heat gently. Allow to cool and add 1 ml of *strong hydrogen peroxide solution R*; repeat by alternating evaporation and addition of hydrogen peroxide solution until a colourless liquid is obtained. Reduce the volume to about 10 ml. Cool and dilute to 50.0 ml with *water R*.

Solution S2. Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 ml of *water for injections R* and cover the neck of the flask with a borosilicate-glass beaker. Heat in an autoclave at 121 ± 2 °C for 20 min. Allow to cool and decant the solution. Make the volume up to 500 ml.

Appearance of solution S2. Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 100 ml of solution S2, add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S2 add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of *0.01 M hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*). Evaporate 100.0 ml of solution S2 to dryness. Dissolve the residue in 5.0 ml of *hexane R*. From 250 nm to 310 nm the absorbance is not greater than 0.25.

Reducing substances. *Carry out the test within 4 h of preparation of solution S2.* To 20.0 ml of solution S2 add 1 ml of *dilute sulphuric acid R* and 20.0 ml of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration using 20 ml of *water for injections R*. The difference between the two titration volumes is not more than 2.0 ml.

Primary aromatic amines. To 2.5 ml of solution A1 obtained during the identification, add 6 ml of *water R* and 4 ml of *0.1 M hydrochloric acid*. Shake vigorously and discard the upper layer. To the aqueous layer add 0.4 ml of a freshly prepared 10 g/l solution of *sodium nitrite R*. Mix and allow to stand for 1 min. Add 0.8 ml of a 25 g/l solution of *ammonium sulphamate R*, allow to stand for 1 min and add 2 ml of a 5 g/l solution of *naphthylethylenediamine dihydrochloride R*. After 30 min, any colour in the solution is not more intense than that in a standard prepared at the same time in the same manner replacing the aqueous layer with a mixture of 1 ml of a 0.01 g/l solution of *naphthylamine R* in *0.1 M hydrochloric acid*, 5 ml of *water R* and 4 ml of *0.1 M hydrochloric acid* instead of the aqueous layer (20 ppm).

Plastic additives 01, 04 and 05. Examine by thin-layer chromatography (*2.2.27*), using a *TLC silica gel GF_{254} plate R* (1 mm thick).

Reference solutions. Prepare 0.1 mg/ml solutions of *plastic additive 01 CRS*, *plastic additive 04 CRS* and *plastic additive 05 CRS*, respectively, in *toluene R*.

Apply to the plate as a band 30 mm by 3 mm, 0.5 ml of solution A1 obtained during the identification. Apply to the plate 5 µl of each reference solution. Develop over a path of 15 cm using *toluene R*. Dry the plate carefully. Examine in ultraviolet light at 254 nm and locate the zone corresponding to plastic additive 01 (R_F about 0.4). Remove the area of silica gel corresponding to this zone and shake with 40 ml of *ether R* for 1 min. Filter, rinse with two quantities, each of 10 ml of *ether R*, add the rinsings to the filtrate and evaporate to dryness. The residue C weighs not more than 40 mg.

Expose the plate to iodine vapour for 5 min. Examine the chromatogram and locate the band corresponding to plastic additives 04 and 05 (R_F = 0). Remove the area of silica gel corresponding to this zone. Similarly remove a corresponding area of silica gel as a blank reference. Separately shake both samples for 15 min with 40 ml of *methanol R*. Filter, rinse with two quantities, each of 10 ml of *methanol R*, add the rinsings to the filtrate and evaporate to dryness. The difference between the masses of both residues is not more than 10 mg.

Plastic additive 03. Wash precipitate B2 obtained during the identification and contained in the tared sintered-glass filter (40) (*2.1.2*) with *ethanol R*. Dry to constant mass over *diphosphorus pentoxide R* and weigh the filter. The precipitate weighs not more than 20 mg.

Examine the residue by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *plastic additive 03 CRS*.

Barium. Not more than 5.0 ppm of Ba, examined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Ignite 1.0 g of the substance to be examined in a silica crucible. Take up the residue with 10 ml of *hydrochloric acid R* and evaporate to dryness on a water-bath. Take up the residue with 20 ml of *0.1 M hydrochloric acid*.

Reference solution. A solution containing 0.25 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Cadmium. Not more than 0.6 ppm of Cd, determined by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Evaporate 10 ml of solution S1 to dryness. Take up the residue using 5 ml of a 1 per cent *V/V* solution of *hydrochloric acid R*, filter and dilute the filtrate to 10.0 ml with the same acid solution.

Reference solutions. Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluted with a 1 per cent *V/V* solution of *hydrochloric acid R*.

Measure the absorbance at 228.8 nm using a cadmium hollow-cathode lamp as the source of radiation and an air-acetylene flame.

Verify the absence of cadmium in the hydrochloric acid used.

Calcium. Not more than 0.07 per cent of Ca, examined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use the test solution prepared for the determination of barium.

Reference solution. A solution containing 50.0 ppm of calcium prepared by dilution of *calcium standard solution (400 ppm Ca) R* with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of calcium at 315.89 nm, the spectral background being taken at 315.60 nm.

Verify the absence of calcium in the hydrochloric acid used.

Tin. Not more than 20.0 ppm of Sn, examined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Dilute solution S1 ten times with *water R* immediately before use.

Reference solution. Introduce 2 ml of *tin standard solution (5 ppm (Sn) R)* into a 50 ml flask containing 5 ml of a 20 per cent *V/V* solution of *sulphuric acid R* and dilute to 50 ml with *water R* immediately before use.

Carry out the determination using the emission of tin at 189.99 nm, the spectral background being taken at 190.10 nm.

Verify the absence of tin in the sulphuric acid used.

Zinc. Not more than 0.20 per cent of Zn, determined by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Dilute solution S1 100 times with *0.1 M hydrochloric acid*.

Reference solutions. Prepare the reference solutions using *zinc standard solution (100 ppm Zn) R*, diluted with *0.1 M hydrochloric acid*.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as the source of radiation and an air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Heavy metals (*2.4.8*). To 10 ml of solution S1 add 0.5 ml of *phenolphthalein solution R* and then *strong sodium hydroxide solution R* until a pale pink colour is obtained. Dilute to 25 ml with *water R*. 12 ml of the solution complies with limit test A (50 ppm). Prepare the standard using *lead standard solution (2 ppm Pb) R*.

Water extractable substances. Evaporate 50 ml of solution S2 to dryness on a water-bath and dry in an oven at 100-105 °C to constant mass. Carry out a blank test with 50.0 ml of *water for injections R*. The residue weighs not more than 7.5 mg (0.3 per cent) taking into account the blank test.

ASSAY

Carry out the oxygen-flask method (*2.5.10*) using 50.0 mg. Absorb the combustion products in 20 ml of *1 M sodium hydroxide*. To the solution obtained add 2.5 ml of *nitric acid R*, 10.0 ml of *0.1 M silver nitrate*, 5 ml of *ferric ammonium sulphate solution R2* and 1 ml of *dibutyl phthalate R*. Titrate with *0.05 M ammonium thiocyanate* until a reddish-yellow colour is obtained. Carry out a blank test.

1 ml of *0.1 M silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

In addition, the following tests are carried out on the sterile and empty containers.

Solution S3. If the container to be examined contains an anticoagulant solution, empty the container and wash the inside with 250 ml of *water for injections R* at 20 ± 1 °C and discard the washings before the preparation of solution S3. Introduce into the container a volume of *water for injections R* corresponding to the volume of solution. Close the container and heat in an autoclave so that the temperature of the liquid is maintained at 110 °C for 30 min. After cooling, fill the container with *water for injections R* to its nominal volume and homogenise.

Reference solution. Heat *water for injections R* in a borosilicate-glass flask in an autoclave at 110 °C for 30 min.

Reducing substances. Immediately after preparation of solution S3, transfer to a borosilicate-glass flask a volume corresponding to 8 per cent of the nominal volume of the container. At the same time, prepare a blank using an equal volume of the freshly prepared reference solution in another borosilicate-glass flask. To each solution add 20.0 ml of *0.002 M potassium permanganate* and 1 ml of *dilute sulphuric acid R*. Allow to stand protected from light for 15 min. To each solution add 0.1 g of *potassium iodide R*. Allow to stand protected from light for 5 min and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. The difference between the two titrations is not more than 2.0 ml.

Acidity or alkalinity. To a volume of solution S3 corresponding to 4 per cent of the nominal capacity of the container add 0.1 ml of *phenolphthalein solution R*. The solution remains colourless. Add 0.4 ml of *0.01 M sodium hydroxide*. The solution is pink. Add 0.8 ml of *0.01 M hydrochloric acid* and 0.1 ml of *methyl red solution R*. The solution is orange-red or red.

Chlorides (*2.4.4*). 15 ml of solution S3 complies with the limit test for chlorides (0.4 ppm). Prepare the standard using a mixture of 1.2 ml of *chloride standard solution (5 ppm Cl) R* and 13.8 ml of *water R*.

Ammonium (*2.4.1*). Dilute 5 ml of solution S3 to 14 ml with *water R*. The solution complies with limit test A (2 ppm).

Water extractable substances. Evaporate 100 ml of solution S3 to dryness on a water-bath. Dry in an oven to constant mass at 100-105 °C. Carry out a blank test using 100 ml of the reference solution. The residue from solution S3 weighs not more than 3 mg, taking into account the blank test.

Absorbance (*2.2.25*). Measure the absorbance of solution S3 from 230 nm to 360 nm, using the reference solution as compensation liquid. At wavelengths from 230 nm to 250 nm, the absorbance is not greater than 0.30. At wavelengths from 251 nm to 360 nm, the absorbance is not greater than 0.10.

Extractable plastic additive 01. Use as the extraction solvent, *alcohol R* diluted with *water R* to have a relative density (*2.2.5*) of 0.9389 to 0.9395, measured with a densimeter.

Stock solution. Dissolve 0.100 g of *plastic additive 01 CRS* in the extraction solvent and dilute to 100.0 ml with the same solvent.

Standard solutions:

(*a*) Dilute 20.0 ml of the stock solution to 100.0 ml with the extraction solvent,

(*b*) Dilute 10.0 ml of the stock solution to 100.0 ml with the extraction solvent,

(*c*) Dilute 5.0 ml of the stock solution to 100.0 ml with the extraction solvent,

(*d*) Dilute 2.0 ml of the stock solution to 100.0 ml with the extraction solvent,

(*e*) Dilute 1.0 ml of the stock solution to 100.0 ml with the extraction solvent.

Measure the absorbances (*2.2.25*) of the standard solutions at the maximum at 272 nm, using the extraction solvent as compensation liquid and plot a curve of absorbance against the concentration of plastic additive 01.

Extraction procedure. Using the donor tubing and the needle or adapter, fill the empty container with a volume equal to half the nominal volume with the extraction solvent, previously heated to 37 °C in a well-stoppered flask. Expel the air completely from the container and seal the donor tubing. Immerse the filled container in a horizontal position in a water-bath maintained at 37 ± 1 °C for 60 ± 1 min without shaking. Remove the container from the water-bath, invert it gently ten times and transfer the contents to a glass flask. Immediately measure the absorbance at the maximum at 272 nm, using the extraction solvent as compensation liquid.

Determine the concentration of plastic additive 01 in milligrams per 100 ml of extract from the calibration curve. The concentration does not exceed:

- 10 mg per 100 ml for containers of nominal volume greater than 300 ml but not greater than 500 ml;
- 13 mg per 100 ml for containers of nominal volume greater than 150 ml but not greater than 300 ml;
- 14 mg per 100 ml for containers of nominal volume up to 150 ml.

Where containers contain an anticoagulant solution, this solution complies with the monograph on Anticoagulant and preservative solutions for human blood (0209) and the following additional test.

Absorbance (*2.2.25*). Measure the absorbance of the anticoagulant solution from the container between 250 nm and 350 nm, using as the compensation liquid an anticoagulant solution of the same composition that has not been in contact with a plastic material. The absorbance at the maximum at 280 nm is not greater than 0.5.

corrected 6.0

3.1.1.2. MATERIALS BASED ON PLASTICISED POLY(VINYL CHLORIDE) FOR TUBING USED IN SETS FOR THE TRANSFUSION OF BLOOD AND BLOOD COMPONENTS

DEFINITION

Materials based on plasticised poly(vinyl chloride for transfusion of blood and blood components contain not less than 55 per cent of poly(vinyl chloride) with di(2-ethylhexyl) phthalate (plastic additive 01) as plasticiser.

PRODUCTION

Materials based on plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test:

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (*2.2.28*), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in

contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject the remaining 25 ml of vinyl chloride slowly into the vial shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into five of the vials. The six solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamide R* and 5 per cent *m/m* of *macrogol 400 R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 45 °C, that of the injection port at 100 °C and that of the detector at 150 °C.

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Almost colourless or pale-yellow material in the form of powder, beads, granules or, after transformation, tubes with a slight odour. On combustion it gives off dense, black smoke.

IDENTIFICATION

If necessary, cut samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. To 0.5 g add 30 ml of *tetrahydrofuran R*. Heat with stirring on a water-bath under a hood for 10 min. The material dissolves completely. Add *methanol R* dropwise with stirring. A granular precipitate is formed. Filter the precipitate and dry at 60 °C. Examine the precipitate by infrared absorption spectrophotometry (*2.2.24*). Dissolve 50 mg in 2 ml of *tetrahydrofuran R* and pour on a glass slide. Dry in an oven at 80 °C, remove the film and fix on a suitable mount. Examine by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *poly(vinyl chloride) CRS*.

B. Examine the residue obtained in the test Plastic additive 01 by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *plastic additive 01 CRS*.

TESTS

If necessary, cut the material to be examined into pieces with a maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 5.0 g of the material to be examined in a combustion flask. Add 30 ml of *sulphuric acid R* and heat until a black, syrupy mass is obtained. Cool and add carefully 10 ml of *strong hydrogen peroxide solution R*. Heat gently. Allow to cool and add 1 ml of *strong hydrogen peroxide solution R*; repeat by alternating evaporation and addition of hydrogen peroxide solution until a colourless liquid is obtained. Reduce the volume to about 10 ml. Cool and dilute to 50.0 ml with *water R*.

Solution S2. Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 ml of *water R* and cover the neck of the flask with a borosilicate-glass beaker. Heat in an autoclave at 121 ± 2 °C for 20 min. Allow to cool and decant the solution and make up to a volume of 500 ml.

Appearance of solution S2. Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Plastic additive 01. Examine by thin-layer chromatography (*2.2.27*), using a *TLC silica gel G plate R*.

Test solution. To 2.0 g of the material to be examined add 200 ml of *peroxide-free ether R* and heat under a reflux condenser for 8 h. Separate the residue and the solution by filtration and evaporate the solution to dryness under reduced pressure in a water-bath at 30 °C. Dissolve the residue in 10 ml of *toluene R*.

Reference solution. Dissolve 0.8 g of *plastic additive 01 CRS* in *toluene R* and dilute to 10 ml with the same solvent.

Apply separately to the plate as a band 30 mm by 3 mm 0.5 ml of the test solution and 5 µl of the reference solution. Develop over a path of 15 cm using *toluene R*. Dry the plate carefully. Examine the chromatogram obtained in ultraviolet light at 254 nm and locate the zone corresponding to plastic additive 01. Remove the area of silica gel corresponding to this zone and shake with 40 ml of *ether R*. Filter without loss and evaporate to dryness. The residue weighs not more than 40 mg.

Barium. Not more than 5.0 ppm of Ba, examined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Ignite 1.0 g of the substance to be examined in a silica crucible. Take up the residue with 10 ml of *hydrochloric acid R* and evaporate to dryness on a water-bath. Take up the residue with 20 ml of *0.1 M hydrochloric acid*.

Reference solution. A solution containing 0.25 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Cadmium. Not more than 0.6 ppm of Cd, determined by atomic absorption spectrophotometry (*2.2.23, Method I*).

Test solution. Evaporate 10.0 ml of solution S1 to dryness. Take up the residue using 5 ml of a 1 per cent *V/V* solution of *hydrochloric acid R*, filter and dilute the filtrate to 10.0 ml with the same acid.

Reference solutions. Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluted with a 1 per cent *V/V* solution of *hydrochloric acid R*.

Measure the absorbance at 228.8 nm using a cadmium hollow-cathode lamp as source of radiation and an air-acetylene flame.

Verify the absence of cadmium in the hydrochloric acid used.

Tin. Not more than 20.0 ppm of Sn, examined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Dilute solution S1 ten times with *water R* immediately before use.

Reference solution. Introduce 2 ml of *tin standard solution (5 ppm Sn) R* into a 50 ml flask containing 5 ml of a 20 per cent *V/V* solution of *sulphuric acid R* and dilute to 50 ml with *water R* immediately before use.

Carry out the determination using the emission of tin at 189.99 nm, the spectral background being taken at 190.10 nm.

Verify the absence of tin in the sulphuric acid used.

Heavy metals (*2.4.8*). To 10 ml of solution S1 add 0.5 ml of *phenolphthalein solution R* and then *strong sodium hydroxide solution R* until a pale pink colour is obtained. Dilute to 25 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (50 ppm). Prepare the standard using *lead standard solution (2 ppm Pb) R*.

ASSAY

To 0.500 g add 30 ml of *tetrahydrofuran R* and heat with stirring on a water-bath under a hood for 10 min. The material dissolves completely. Add 60 ml of *methanol R* dropwise with stirring. A granular precipitate of poly(vinyl chloride) is formed. Allow to stand for a few minutes. Continue addition of *methanol R* until no further precipitation is observed. Transfer to a sintered-glass filter (40) (*2.1.2*), using three small quantities of *methanol R* to aid transfer and to wash the precipitate. Dry the filter and the precipitate to constant mass at 60 °C and weigh.

In addition, carry out the following tests on sterilised sets.

Solution S3. Make a closed circulation system from three sets and a 300 ml borosilicate-glass vessel. Fit to the vessel a thermostat device that maintains the temperature of the liquid in the vessel at 37 ± 1 °C. Circulate 250 ml of *water for injections R* through the system in the direction used for transfusion for 2 h at a rate of 1 litre per hour (for example using a peristaltic pump applied to as short a piece of suitable silicone tubing as possible). Collect the whole of the solution and allow to cool.

Appearance of solution. Solution S3 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 25 ml of solution S3 add 0.15 ml of *BRP indicator solution R*. Not more than 0.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 25 ml of solution S3 add 0.2 ml of *methyl orange solution R*. Not more than 0.5 ml of *0.01 M hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*). Examined from 230 nm to 250 nm, solution S3 shows no absorbance greater than 0.30. Examined from 251 nm to 360 nm, solution S3 shows no absorbance greater than 0.15.

Reducing substances. Carry out the test within 4 h of preparation of solution S3. To 20.0 ml of solution S3 add 1 ml of *dilute sulphuric acid R* and 20.0 ml of *0.002 M potassium permanganate*. Boil for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate with *0.01 M sodium thiosulphate* using 0.25 ml of *starch solution R* as indicator. Carry out a blank test using 20 ml of *water for injections R*. The difference between the titration volumes is not greater than 2.0 ml.

Water extractable substances. Evaporate 50.0 ml of solution S3 to dryness on a water-bath and dry to constant mass in an oven at 100 °C to 105 °C. Carry out a blank test using 50.0 ml of *water for injections R*. The residue obtained with solution S3 is not greater than 1.5 mg, taking account of the blank test.

corrected 6.0

3.1.3. POLYOLEFINES

DEFINITION

Polyolefines are obtained by polymerisation of ethylene or propylene or by copolymerisation of these substances with not more than 25 per cent of higher homologues (C_4 to C_{10}) or of carboxylic acids or of esters. Certain materials may be mixtures of polyolefines.

PRODUCTION

A certain number of additives are added to the polymer in order to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All of these additives are chosen from the appended list which specifies for each product the maximum allowable content.

They may contain at most 3 antioxidants, one or several lubricants or antiblocking agents as well as titanium dioxide as an opacifying agent when the material must provide protection from light.

- butylhydroxytoluene (plastic additive 07) (not more than 0.125 per cent),
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09) (not more than 0.3 per cent),
- 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-*s*-triazine-2,4,6(1*H*,3*H*,5*H*)-trione, (plastic additive 13) (not more than 0.3 per cent),
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate (plastic additive 11) (not more than 0.3 per cent),
- ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08) (not more than 0.3 per cent),
- dioctadecyl disulphide (plastic additive 15) (not more than 0.3 per cent),
- 4,4′,4″-(2,4,6-trimethylbenzene-1,3,5-triyltrismethylene)trio[2,6-bis(1,1-dimethylethyl)phenol] (plastic additive 10) (not more than 0.3 per cent),
- 2,2′-bis(octadecyloxy)-5,5′-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14) (not more than 0.3 per cent),
- didodecyl 3,3′-thiodipropionate (plastic additive 16) (not more than 0.3 per cent),
- dioctadecyl 3,3′-thiodipropionate (plastic additive 17) (not more than 0.3 per cent),
- tris[2,4-bis(1,1-dimethylethyl)phenyl] phosphite (plastic additive 12) (not more than 0.3 per cent),
- plastic additive 18 (not more than 0.1 per cent),
- copolymer of dimethyl succinate and (4-hydroxy-2,2,6,6-tetramethylpiperidin-1-yl)ethanol (plastic additive 22) (not more than 0.3 per cent).

The total of antioxidant additives listed above does not exceed 0.3 per cent.

- hydrotalcite (not more than 0.5 per cent),
- alkanamides (not more than 0.5 per cent),
- alkenamides (not more than 0.5 per cent),

- sodium silico-aluminate (not more than 0.5 per cent),
- silica (not more than 0.5 per cent),
- sodium benzoate (not more than 0.5 per cent),
- fatty acid esters or salts (not more than 0.5 per cent),
- trisodium phosphate (not more than 0.5 per cent),
- liquid paraffin (not more than 0.5 per cent),
- zinc oxide (not more than 0.5 per cent),
- talc (not more than 0.5 per cent),
- magnesium oxide (not more than 0.2 per cent),
- calcium stearate or zinc stearate or a mixture of both (not more than 0.5 per cent),
- titanium dioxide (not more than 4 per cent).

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules or, after transformation, sheets of varying thickness or containers. They are practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in hexane and in methanol. They soften at temperatures between 65 °C and 165 °C. They burn with a blue flame.

IDENTIFICATION

If necessary, cut samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution obtained on a sodium chloride slide and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (*2.2.24*). The spectrum of the material to be examined shows maxima in particular at some of the following wave-numbers: 2920 cm^{-1}, 2850 cm^{-1}, 1475 cm^{-1}, 1465 cm^{-1}, 1380 cm^{-1}, 1170 cm^{-1}, 735 cm^{-1}, 720 cm^{-1}; the spectrum obtained is identical to the spectrum obtained with the material selected for the type sample. If the material to be examined is in the form of sheets, the identification may be determined directly on a cut piece of suitable size.

B. It complies with the supplementary tests corresponding to the additives present.

C. In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulphate R* and heat until completely melted. Allow to cool and add 20 ml of *dilute sulphuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 ml of *phosphoric acid R* and 1 ml of *strong hydrogen peroxide solution R*. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. *Use solution S1 within 4 h of preparation.* Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution S1 and filter the rest through a sintered-glass filter (16) (*2.1.2*).

Solution S2. Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and boil under a reflux condenser with constant stirring for 90 min. Allow to cool to 60 °C and add with continued stirring 120 ml of *methanol R*. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsings to the filtrate and dilute to 250 ml with the same mixture of solvents. Prepare a blank solution.

Solution S3. Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 ml of *0.1 M hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution S1. Solution S1 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 100 ml of solution S1, add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S1 add 0.2 ml of *methyl orange solution R*. Not more than 1 ml of *0.01 M hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*). At wavelengths from 220 nm to 340 nm, the absorbance of solution S1 is not greater than 0.2.

Reducing substances. To 20 ml of solution S1 add 1 ml of *dilute sulphuric acid R* and 20 ml of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 3.0 ml.

Substances soluble in hexane. Place 10 g in a 250 ml conical borosilicate-glass flask with a ground-glass neck. Add 100 ml of *hexane R* and boil under a reflux condenser for 4 h, stirring constantly. Cool in iced water and filter rapidly (the filtration time must be less than 5 min; if necessary the filtration may be accelerated by applying pressure to the solution) through a sintered-glass filter (16) (*2.1.2*) maintaining the solution at about 0 °C. Evaporate 20 ml of the filtrate in a tared borosilicate-glass dish on a water-bath. Dry the residue in an oven at 100-105 °C for 1 h. The mass of the residue obtained must be within 10 per cent of that of the residue obtained with the type sample and does not exceed 5 per cent.

Extractable aluminium. Not more than 1.0 ppm of extractable Al, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluted with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable titanium. Not more than 1.0 ppm of extractable Ti, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluted with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable zinc. Not more than 1.0 ppm of extractable Zn, determined by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R*, diluted with *0.1 M hydrochloric acid*.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as a source of radiation and an air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Extractable heavy metals (*2.4.8*). Evaporate 50 ml of solution S3 to about 5 ml on a water-bath and dilute to 20.0 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (2.5 ppm). Prepare the standard using 2.5 ml of *lead standard solution (10 ppm Pb) R*.

Sulphated ash (*2.4.14*). Not more than 1.0 per cent, determined on 5.0 g. This limit does not apply to material that has been opacified with titanium dioxide.

SUPPLEMENTARY TESTS

These tests are to be carried out, in whole or in part, only if required by the stated composition or the use of the material.

Phenolic antioxidants. Examine by liquid chromatography (*2.2.29*).

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase one of the 4 following mixtures:

  Mobile phase 1 at a flow rate of 2 ml/min: 30 volumes of *water R*, 70 volumes of *acetonitrile R*,

  Mobile phase 2 at a flow rate of 1.5 ml/min: 10 volumes of *water R*, 30 volumes of *tetrahydrofuran R*, 60 volumes of *acetonitrile R*,

  Mobile phase 3 at a flow rate of 1.5 ml/min: 5 volumes of *water R*, 45 volumes of *2-propanol R*, 50 volumes of *methanol R*,

  Mobile phase 4 at a flow rate of 1.5 ml/min: 20 volumes of *tetrahydrofuran R*, 80 volumes of *acetonitrile R*,
- as detector a spectrophotometer set at 280 nm for mobile phases 1 to 3, and set at 270 nm for mobile phase 4.

The chromatographic system must ensure the following:

- a resolution of not less than 8.0 between the peaks corresponding to plastic additive 07 and plastic additive 08, with mobile phase 1,
- a resolution of not less than 2.0 between the peaks corresponding to plastic additive 09 and plastic additive 10, with mobile phase 2,
- a resolution of not less than 2.0 between the peaks corresponding to plastic additive 11 and plastic additive 12, with mobile phase 3,
- a resolution of not less than 6.0 between the 2 principal peaks (approximate retention times of 3.5 and 5.8) in the chromatogram obtained with plastic additive 18, with mobile phase 4.

Test solution S21. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S22. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue with 5.0 ml of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S23. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 ml of a mixture of equal volumes of *acetonitrile R* and a 10 g/l solution of *tert-butylhydroperoxide R* in *tetrahydrofuran R*. Close the flask and allow to stand for 1 h. Prepare a blank solution using the blank of solution S2.

Of the following reference solutions, prepare only those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (b). Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (c). Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml to 50.0 ml with *methylene chloride R*.

Reference solution (d). Dissolve 25.0 mg of *plastic additive 07 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (e). Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (f). Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (g). Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (h). Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (i). Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml to 50.0 ml with *methylene chloride R*.

Reference solution (j). Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml to 50.0 ml with *methylene chloride R*.

Reference solution (k). Dissolve 20.0 mg of *plastic additive 18 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and a 10 g/l solution of *tert-butylhydroperoxide R* in *tetrahydrofuran R*. Allow to stand in a closed container for 1 h. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

If the substance to be examined contains plastic additive 07 and/or plastic additive 08, use mobile phase 1 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (a), and either 20 µl each of reference solutions (d) or (e) or 20 µl each of reference solutions (d) and (e).

If the substance to be examined contains one or more of the following antioxidants:

– plastic additive 09,
– plastic additive 10,
– plastic additive 11,
– plastic additive 12,
– plastic additive 13,

use mobile phase 2 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (b) and 20 µl of each of the reference solutions of the antioxidants on the list above that are stated in the composition.

If the substance to be examined contains plastic additive 11 and/or plastic additive 12, use mobile phase 3 and inject 20 µl of test solution S22, 20 µl of the corresponding blank solution, 20 µl of reference solution (c), and either 20 µl of reference solution (i) or (j) or 20 µl of reference solutions (i) and (j).

If the substance to be examined contains plastic additive 18, use mobile phase 4 and inject 20 µl of test solution S23, 20 µl of the corresponding blank solution, and 20 µl of reference solution (k).

In all cases, record the chromatogram for 30 min; the chromatograms corresponding to test solutions S21, S22 and S23 only show peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatograms corresponding to the blank solutions. The areas of the peaks corresponding to test solutions S21, S22 and S23 are less than the corresponding areas of the peaks in the chromatograms obtained with reference solutions (d) to (k).

Non-phenolic antioxidants. Examine by thin-layer chromatography (*2.2.27*), using a *TLC silica gel GF_{254} plate R*.

Test solution S24. Evaporate 100 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 ml of *acidified methylene chloride R*.

Reference solution (l). Dissolve 60 mg of *plastic additive 14 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (m). Dissolve 60 mg of *plastic additive 15 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (n). Dissolve 60 mg of *plastic additive 16 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (o). Dissolve 60 mg of *plastic additive 17 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (p). Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Apply separately to the plate 20 µl of test solution S24, 20 µl of reference solution (p) and 20 µl of each of the reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined.

Develop over a path of 18 cm using *hexane R*. Allow the plate to dry. Develop a second time over a path of 17 cm using *methylene chloride R*. Allow the plate to dry and examine in ultraviolet light at 254 nm. Spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10-15 min. Any spots in the chromatogram obtained with test solution S24 are not more intense than the spots in the corresponding positions in the chromatograms obtained with the reference solutions. The test is not valid unless the chromatogram obtained with reference solution (p) shows 2 clearly separated spots.

Plastic additive 22. Examine by liquid chromatography (*2.2.29*).

Test solution. Evaporate 25 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 10 ml of *toluene R* and 10 ml of a 10 g/l solution of *tetrabutylammonium hydroxide R* in a mixture of 35 volumes of *toluene R* and 65 volumes of *ethanol R*. Boil under a reflux condenser for 3 h. Allow to cool and filter if necessary.

Reference solution. Dissolve 30 mg of *plastic additive 22 CRS* in 50 ml of *toluene R*. Add 1 ml of this solution to 25 ml of blank solution S2 and evaporate to dryness *in vacuo* at 45 °C. Dissolve the residue in 10 ml of *toluene R* and 10 ml of a 10 g/l solution of *tetrabutylammonium hydroxide R* in a mixture of 35 volumes of *toluene R* and 65 volumes of *ethanol R*. Boil under a reflux condenser for 3 h. Allow to cool and filter if necessary.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *aminopropylsilyl silica gel for chromatography R* (5 µm),
– as mobile phase at a flow rate of 2 ml/min a mixture of 11 volumes of *ethanol R* and 89 volumes of *hexane R*,
– as detector a spectrophotometer set at 227 nm.

Inject 20 µl of each solution. Record the chromatograms for 10 min. When the chromatograms are recorded in the prescribed conditions the resolution between the peaks corresponding respectively to the “diol” and diluent of the reference solution is at least 7.

In the chromatogram obtained with the test solution, the area of the peak corresponding to the “diol” component from plastic additive 22 is less than the corresponding peak in the chromatogram obtained with the reference solution.

Amides and stearates. Examine by thin-layer chromatography (*2.2.27*), using 2 plates of the *TLC silica gel GF_{254} plate R* type.

Test solution. Use test solution S24 described in the test for non-phenolic antioxidants.

Reference solution (q). Dissolve 20 mg of stearic acid (*plastic additive 19 CRS*) in 10 ml of *methylene chloride R*.

Reference solution (r). Dissolve 40 mg of oleamide (*plastic additive 20 CRS*) in 20 ml of *methylene chloride R*.

Reference solution (s). Dissolve 40 mg of erucamide (*plastic additive 21 CRS*) in 20 ml of *methylene chloride R*.

Apply to the 2 plates 10 µl of test solution S24. Apply 10 µl of reference solution (q) to the first plate and 10 µl each of reference solutions (r) and (s) to the second plate.

Develop the first plate over a path of 10 cm using a mixture of 25 volumes of *ethanol R* and 75 volumes of *trimethylpentane R*. Allow the plate to dry in air. Spray with a 2 g/l solution of *dichlorophenolindophenol, sodium salt R* in *ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots. Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S24 is identical in position to (R_F about 0.5) but not more intense than the spot in the chromatogram obtained with reference solution (q).

Develop the second plate over a path of 13 cm using *hexane R*. Allow the plate to dry in air. Develop a second time over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry. Spray with a 40 g/l solution of *phosphomolybdic acid R* in *ethanol R*. Heat in an oven at 120 °C until spots appear. Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with test solution S24 are identical in position to (R_F about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (r) and (s).

corrected 6.0

3.1.4. POLYETHYLENE WITHOUT ADDITIVES FOR CONTAINERS FOR PARENTERAL PREPARATIONS AND FOR OPHTHALMIC PREPARATIONS

DEFINITION

Polyethylene without additives is obtained by the polymerisation of ethylene under high pressure in the presence of oxygen or free-radical-forming initiators as catalyst.

CHARACTERS

Beads, granules, powder or, after transformation, translucent sheets of varying thickness or containers, practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in hexane and in methanol. It softens at temperatures beginning at 65 °C.

The relative density (*2.2.5*) of the material is 0.910 to 0.937.

IDENTIFICATION

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride disc and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (*2.2.24*). The spectrum of the substance to be examined shows maxima in particular at some of the following wave-numbers: 2920 cm^{-1}, 2850 cm^{-1}, 1465 cm^{-1}, 730 cm^{-1}, 720 cm^{-1}; the spectrum obtained is identical to that obtained with the material selected for the type sample. If the material to be examined is in the form of sheets, the identification may be performed directly on a cut piece of suitable size.

B. The substance to be examined complies with the test for additives (see Tests).

TESTS

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and heat under a reflux condenser for 5 h. Allow to cool and decant. Keep part of the solution for the test for appearance of solution. Filter the rest through a sintered glass filter (16) (*2.1.2*). *Use solution S1 within 4 h of preparation.*

Solution S2. Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and boil under a reflux condenser with constant stirring for 1 h 30 min. Allow to cool to 60 °C and add with continued stirring 120 ml of *methanol R*. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsings to the filtrate and dilute to 250 ml with the same mixture of solvents. Prepare a blank solution.

Solution S3. Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 ml of *0.1 M hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution. Solution S1 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 100 ml of solution S1 add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S1 add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*). At wavelengths from 220 nm to 340 nm, the absorbance of solution S1 is not greater than 0.2.

Reducing substances. To 20 ml of solution S1 add 1 ml of *dilute sulphuric acid R* and 20 ml of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add l g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 ml.

Substances soluble in hexane. Place 10 g in a 250 ml conical borosilicate-glass flask with a ground-glass neck. Add 100 ml of *hexane R* and boil under a reflux condenser for 4 h, stirring constantly. Cool in iced water and filter rapidly through a sintered-glass filter (16) (*2.1.2*) maintaining the solution at 0 °C (the filtration time must be less than 5 min; if necessary the filtration may be accelerated by applying pressure to the solution). Evaporate 20 ml of the filtrate in a tared glass dish on a water-bath. Dry the residue in an oven at 100-105 °C for 1 h. The mass of the residue obtained is within 10 per cent of the residue obtained with the type sample and does not exceed 5 per cent.

Additives. Examine by thin-layer chromatography (*2.2.27*), using a *TLC silica gel G plate R*.

Test solution. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the evaporation residue with 5 ml of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Reference solution. Dissolve 20 mg of *plastic additive 15 CRS* and 20 mg of *plastic additive 08 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent.

Apply to the plate 10 µl of each solution. Develop over a path of 13 cm using *hexane R*. Allow the plate to dry in air. Carry out a second development over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes

of *methylene chloride R*. Allow the plate to dry in air, spray with a 40 g/l solution of *phosphomolybdic acid R* in *alcohol R* and heat at 120 °C until the spots appear in the chromatogram obtained with the reference solution. No spot appears in the chromatogram obtained with the test solution, except for a spot which may be at the solvent front from the first development and which corresponds to oligomers. Disregard any spots corresponding to those obtained in the chromatogram with the blank solution. The chromatogram obtained with the reference solution shows two distinct spots.

Extractable heavy metals (*2.4.8*). Evaporate 50 ml of solution S3 to about 5 ml on a water-bath and dilute to 20 ml with *water R*. 12 ml of solution complies with limit test A for heavy metals (2.5 ppm). Prepare the standard using 2.5 ml of *lead standard solution (10 ppm Pb) R*.

Sulphated ash (*2.4.14*). Not more than 0.02 per cent, determined on 5.0 g.

01/2008:30105
corrected 6.0

3.1.5. POLYETHYLENE WITH ADDITIVES FOR CONTAINERS FOR PARENTERAL PREPARATIONS AND FOR OPHTHALMIC PREPARATIONS

DEFINITION

Polyethylene with additives is obtained by the polymerisation of ethylene under pressure in the presence of a catalyst or by copolymerisation of ethylene with not more than 25 per cent of higher alkene homologues (C_3 to C_{10}).

PRODUCTION

A certain number of additives are added to the polymer in order to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the appended list which specifies for each product the maximum allowable content.

They may contain at most three antioxidants, one or several lubricants or antiblocking agents as well as titanium dioxide as an opacifying agent when the material must provide protection from light.

- butylhydroxytoluene (plastic additive 07) (not more than 0.125 per cent),
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09) (not more than 0.3 per cent),
- 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-*s*-triazine-2,4,6(1*H*,3*H*,5*H*)-trione (plastic additive 13) (not more than 0.3 per cent),
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate, (plastic additive 11) (not more than 0.3 per cent),
- ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08) (not more than 0.3 per cent),
- dioctadecyl disulphide (plastic additive 15) (not more than 0.3 per cent),
- 4,4′,4″-(2,4,6-trimethylbenzene-1,3,5-triyltrismethylene)tris[2,6-bis(1,1-dimethylethyl)phenol] (plastic additive 10) (not more than 0.3 per cent),
- 2,2′-bis(octadecyloxy)-5,5′-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14) (not more than 0.3 per cent),
- didodecyl 3,3′-thiodipropionate (plastic additive 16) (not more than 0.3 per cent),
- dioctadecyl 3,3′-thiodipropionate (plastic additive 17) (not more than 0.3 per cent),
- tris [2,4-bis(1,1-dimethylethyl)phenyl] phosphite (plastic additive 12) (not more than 0.3 per cent).

The total of antioxidant additives listed above does not exceed 0.3 per cent.

- hydrotalcite (not more than 0.5 per cent),
- alkanamides (not more than 0.5 per cent),
- alkenamides (not more than 0.5 per cent),
- sodium silico-aluminate (not more than 0.5 per cent),
- silica (not more than 0.5 per cent),
- sodium benzoate (not more than 0.5 per cent),
- fatty acid esters or salts (not more than 0.5 per cent),
- trisodium phosphate (not more than 0.5 per cent),
- liquid paraffin (not more than 0.5 per cent),
- zinc oxide (not more than 0.5 per cent),
- magnesium oxide (not more than 0.2 per cent),
- calcium stearate or zinc stearate or a mixture of both (not more than 0.5 per cent),
- titanium dioxide (not more than 4 per cent) only for materials for containers for ophthalmic use.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules or, after transformation, translucent sheets of varying thicknesses or containers. It is practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in hexane and in methanol. It softens at temperatures between 70 °C and 140 °C.

The relative density (*2.2.5*) of the material is 0.890 to 0.965.

IDENTIFICATION

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride disc and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (*2.2.24*). The spectrum of the material to be examined shows maxima in particular at some of the following wave-numbers: 2920 cm^{-1}, 2850 cm^{-1}, 1465 cm^{-1}, 1375 cm^{-1}, 1170 cm^{-1}, 730 cm^{-1}, 720 cm^{-1}; the spectrum obtained is identical to the spectrum obtained with the material selected for the type sample. If the material to be examined is in the form of sheets, the identification may be performed directly on a cut piece of suitable size.

B. It complies with the supplementary tests corresponding to the additives present (see Tests).

C. In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulphate R* and heat until completely melted. Allow to cool and add 20 ml of *dilute sulphuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 ml of *phosphoric acid R* and 1 ml of

strong hydrogen peroxide solution R. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution and filter the rest through a sintered-glass filter (16) (*2.1.2*). *Use within 4 h of preparation.*

Solution S2. Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and boil under a reflux condenser with constant stirring for 90 min. Allow to cool to 60 °C and add with continued stirring 120 ml of *methanol R*. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsings to the filtrate and dilute to 250.0 ml with the same mixture of solvents. Prepare a blank solution.

Solution S3. Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 ml of *0.1 M hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution. Solution S1 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 100 ml of solution S1 add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S1 add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*). At wavelengths from 220 nm to 340 nm, the absorbance of solution S1 is not greater than 0.2.

Reducing substances. To 20 ml of solution S1 add 1 ml of *dilute sulphuric acid R* and 20 ml of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 ml.

Substances soluble in hexane. Place 10 g in a 250 ml conical borosilicate-glass flask with a ground-glass neck. Add 100 ml of *hexane R* and boil under a reflux condenser for 4 h, stirring constantly. Cool in iced water and filter rapidly through a sintered-glass filter (16) (*2.1.2*) maintaining the solution at 0 °C (the filtration time must be less than 5 min; if necessary the filtration may be accelerated by applying pressure to the solution). Evaporate 20 ml of the filtrate in a tared borosilicate-glass dish on a water-bath. Dry the residue in an oven at 100-105 °C for 1 h. The mass of the residue obtained must be within 10 per cent of the residue obtained with the type sample and does not exceed 5 per cent.

Extractable aluminium. Not more than 1.0 ppm of extractable Al, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluted with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable chromium. Not more than 0.05 ppm of extractable Cr, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *chromium standard solution (100 ppm Cr) R*, diluted with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Carry out the determination using the emission of chromium at 205.55 nm, the spectral background being taken as 205.50 nm.

Verify the absence of chromium in the hydrochloric acid used.

Extractable titanium. Not more than 1.0 ppm of extractable Ti, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluted with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable vanadium. Not more than 0.1 ppm of extractable V, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *vanadium standard solution (1 g/l V) R*, diluting with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Carry out the determination using the emission of vanadium at 292.40 nm, the spectral background being taken as 292.35 nm.

Verify the absence of vanadium in the hydrochloric acid used.

Extractable zinc. Not more than 1.0 ppm of extractable Zn, determined by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R*, diluted with *0.1 M hydrochloric acid*.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as a source of radiation and an air-acetylene flame.

Extractable zirconium. Not more than 0.1 ppm of extractable Zr, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *zirconium standard solution (1 g/l Zr) R*, diluted with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Carry out the determination using the emission of zirconium at 343.82 nm, the spectral background being taken as 343.92 nm.

Verify the absence of zirconium in the hydrochloric acid used.

Extractable heavy metals (*2.4.8*). Evaporate 50 ml of solution S3 to about 5 ml on a water-bath and dilute to 20.0 ml with *water R*. 12 ml of solution complies with limit test A for heavy metals (2.5 ppm). Prepare the standard using 2.5 ml of *lead standard solution (10 ppm Pb) R*.

Sulphated ash (*2.4.14*). Not more than 1.0 per cent, determined on 5.0 g. This limit does not apply to material opacified with titanium dioxide.

SUPPLEMENTARY TESTS

These tests are to be carried out, in whole or in part, only if required by the stated composition of the material.

Phenolic antioxidants. Examine by liquid chromatography (*2.2.29*).

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),

– as mobile phase one of the 3 following mixtures:

  Mobile phase 1 at a flow rate of 2 ml/min: 30 volumes of *water R*, 70 volumes of *acetonitrile R*,

  Mobile phase 2 at a flow rate of 1.5 ml/min: 10 volumes of *water R*, 30 volumes of *tetrahydrofuran R*, 60 volumes of *acetonitrile R*,

  Mobile phase 3 at a flow rate of 1.5 ml/min: 5 volumes of *water R*, 45 volumes of *2-propanol R*, 50 volumes of *methanol R*,

– as detector a spectrophotometer set at 280 nm.

The chromatographic system must ensure the following:

– a resolution of not less than 8.0 between the peaks corresponding respectively to plastic additive 07 and plastic additive 08, with mobile phase 1,

– a resolution of not less than 2.0 between the peaks corresponding respectively to plastic additive 09 and plastic additive 10, with mobile phase 2,

– a resolution of not less than 2.0 between the peaks corresponding respectively to plastic additive 11 and plastic additive 12, with mobile phase 3.

Test solution S21. Evaporate 50 ml of solution S2 to dryness in vacuo at 45 °C. Dissolve the residue with 5.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S22. Evaporate 50 ml of solution S2 to dryness in vacuo at 45 °C. Dissolve the residue with 5.0 ml of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Of the following reference solutions, only prepare those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (b). Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (c). Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

Reference solution (d). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (e). Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (f). Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (g). Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (h). Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (i). Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

Reference solution (j). Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

If the substance to be examined contains plastic additive 07 and/or plastic additive 08, use mobile phase 1 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (a), and either 20 µl of reference solution (d) or (e), or 20 µl of reference solutions (d) and (e).

If the substance to be examined contains one or more of the following antioxidants:

– plastic additive 09,
– plastic additive 10,
– plastic additive 11,
– plastic additive 12,
– plastic additive 13,

use mobile phase 2 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (b) and 20 µl of the reference solutions of the antioxidants on the list above that are stated in the composition.

If the substance to be examined contains plastic additive 11 and/or plastic additive 12, use mobile phase 3 and inject 20 µl of test solution S22, 20 µl of the corresponding blank solution, 20 µl of reference solution (c), and either 20 µl of reference solution (i) or (j), or 20 µl of reference solutions (i) and (j).

In all cases record the chromatograms for 30 min; the chromatograms corresponding to test solutions S21 and S22 only show peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatograms corresponding to the blank solutions. The

areas of the peaks of test solutions S21 and S22 are less than the areas of the corresponding peaks in the chromatograms obtained with reference solutions (d) to (j).

Non-phenolic antioxidants. Examine by thin-layer chromatography (*2.2.27*), using a *TLC silica gel GF_{254} plate R*.

Test solution S23. Evaporate 100 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 ml of *acidified methylene chloride R*.

Reference solution (k). Dissolve 60 mg of *plastic additive 14 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (l). Dissolve 60 mg of *plastic additive 15 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (m). Dissolve 60 mg of *plastic additive 16 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (n). Dissolve 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (o). Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Apply separately to the plate 20 µl of test solution S23, 20 µl of reference solution (o) and 20 µl of the reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined.

Develop over a path of 18 cm using *hexane R*. Allow the plate to dry. Develop a second time over a path of 17 cm using *methylene chloride R*. Allow the plate to dry and examine in ultraviolet light at 254 nm. Spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10-15 min. Any spots in the chromatogram obtained with test solution S23 are not more intense than the spots in the same locations in the chromatograms obtained with the reference solutions. The test is not valid unless the chromatogram obtained with reference solution (o) shows two clearly separated spots.

Amides and stearates. Examine by thin-layer chromatography (*2.2.27*), using 2 plates of the *TLC silica gel GF_{254} plates R* type.

Test solution. Use test solution S23 described in the test for non-phenolic antioxidants.

Reference solution (p). Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in *methylene chloride R* and dilute to 10 ml with the same solvent.

Reference solution (q). Dissolve 40 mg of *plastic additive 20 CRS* in *methylene chloride R* and dilute to 20 ml with the same solvent.

Reference solution (r). Dissolve 40 mg of *plastic additive 21 CRS* in *methylene chloride R* and dilute to 20 ml with the same solvent.

Apply to each of the 2 plates 10 µl of test solution S23. Apply 10 µl of reference solution (p) to the first and 10 µl of reference solutions (q) and (r) to the second. Develop the first plate over a path of 10 cm using a mixture of 25 volumes of *ethanol R* and 75 volumes of *trimethylpentane R*. Allow the plate to dry in air. Spray with a 2 g/l solution of *dichlorophenolindophenol sodium salt R* in *ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots. Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S23 is identical in position (R_F about 0.5) but not more intense than the spot in the same location in the chromatogram obtained with reference solution (p).

Develop the second plate over a path of 13 cm using *hexane R*. Allow the plate to dry in air. Develop a second time over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry. Spray with a 40 g/l solution of *phosphomolybdic acid R* in *ethanol R*. Heat in an oven at 120 °C until spots appear. Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with test solution S23 are identical in position (R_F about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (q) and (r).

corrected 6.0

3.1.6. POLYPROPYLENE FOR CONTAINERS AND CLOSURES FOR PARENTERAL PREPARATIONS AND OPHTHALMIC PREPARATIONS

DEFINITION

Polypropylene consists of the homopolymer of propylene or of a copolymer of propylene with not more than 25 per cent of ethylene or of a mixture (alloy) of polypropylene with not more than 25 per cent of polyethylene. It may contain additives.

PRODUCTION

A certain number of additives are added to the polymer in order to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the appended list which specifies for each product the maximum allowable content.

They may contain at most three antioxidants, one or several lubricants or antiblocking agents as well as titanium dioxide as opacifying agent when the material must provide protection from light.

- butylhydroxytoluene (plastic additive 07) (not more than 0.125 per cent),
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09) (not more than 0.3 per cent),
- 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-*s*-triazine-2,4,6(1*H*,3*H*,5*H*)-trione (plastic additive 13) (not more than 0.3 per cent),
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate, (plastic additive 11) (not more than 0.3 per cent),
- ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08) (not more than 0.3 per cent),
- dioctadecyl disulphide (plastic additive 15) (not more than 0.3 per cent),
- 2,2′,2″,6,6′,6″-hexa-*tert*-butyl-4,4′,4″-[(2,4,6-trimethyl-1,3,5-benzenetriyl)trismethylene]triphenol (plastic additive 10) (not more than 0.3 per cent),
- 2,2′-bis(octadecyloxy)-5,5′-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14) (not more than 0.3 per cent),

- didodecyl 3,3′-thiodipropionate (plastic additive 16) (not more than 0.3 per cent),
- dioctadecyl 3,3′-thiodipropionate (plastic additive 17) (not more than 0.3 per cent),
- tris(2,4-di-*tert*-butylphenyl) phosphite (plastic additive 12) (not more than 0.3 per cent),

The total of antioxidant additives listed above does not exceed 0.3 per cent.

- hydrotalcite (not more than 0.5 per cent),
- alkanamides (not more than 0.5 per cent),
- alkenamides (not more than 0.5 per cent),
- sodium silico-aluminate (not more than 0.5 per cent),
- silica (not more than 0.5 per cent),
- sodium benzoate (not more than 0.5 per cent),
- fatty acid esters or salts (not more than 0.5 per cent),
- trisodium phosphate (not more than 0.5 per cent),
- liquid paraffin (not more than 0.5 per cent),
- zinc oxide (not more than 0.5 per cent),
- talc (not more than 0.5 per cent),
- magnesium oxide (not more than 0.2 per cent),
- calcium stearate or zinc stearate or a mixture of both (not more than 0.5 per cent),
- titanium dioxide (not more than 4 per cent) only for materials for containers for ophthalmic use.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules or, after transformation, translucent sheets of varying thicknesses or containers. It is practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in hexane and in methanol. It softens at temperatures beginning at about 120 °C.

IDENTIFICATION

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the hot solution on a sodium chloride disc and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (*2.2.24*). The spectrum obtained with the material to be examined presents a certain number of maxima, in particular at 1375 cm^{-1}, 1170 cm^{-1}, 995 cm^{-1} and 970 cm^{-1}. The spectrum obtained is identical to the spectrum obtained with the material selected for the type sample. If the material to be examined is in the form of sheets, the identification may be performed directly on a cut piece of suitable size.

B. It complies with the supplementary tests corresponding to the additives present (see Tests).

C. In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulphate R* and heat until completely melted. Allow to cool and add 20 ml of *dilute sulphuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 ml of *phosphoric acid R* and 1 ml of *strong hydrogen peroxide solution R*. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. *Use solution S1 within 4 h of preparation.* Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution and filter the rest through a sintered-glass filter (16) (*2.1.2*).

Solution S2. Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and boil under a reflux condenser with constant stirring for 1 h 30 min. Allow to cool to 60 °C and add with continued stirring 120 ml of *methanol R*. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsings to the filtrate and dilute to 250.0 ml with the same mixture of solvents. Prepare a blank solution.

Solution S3. Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 ml of *0.1 M hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution. Solution S1 is not more opalescent than reference suspension II (*2.2.1*) and is colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 100 ml of solution S1 add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S1 add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*). At wavelengths from 220 nm to 340 nm, the absorbance of solution S1 is not greater than 0.2.

Reducing substances. To 20 ml of solution S1 add 1 ml of *dilute sulphuric acid R* and 20 ml of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 ml.

Substances soluble in hexane. Place 10 g in a 250 ml conical borosilicate-glass flask with a ground-glass neck. Add 100 ml of *hexane R* and boil under a reflux condenser for 4 h, stirring constantly. Cool in iced water and filter rapidly through a sintered-glass filter (16) (*2.1.2*) maintaining the solution at 0 °C (the filtration time must be less than 5 min; if necessary the filtration may be accelerated by applying pressure to the solution). Evaporate 20 ml of the filtrate in a tared glass dish on a water-bath. Dry the residue in an oven at 100 °C to 105 °C for 1 h. The mass of the residue obtained must be within 10 per cent of the residue obtained with the type sample and does not exceed 5 per cent.

Extractable aluminium. Not more than 1.0 ppm of extractable Al, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluted with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable chromium. Not more than 0.05 ppm of extractable Cr, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *chromium standard solution (100 ppm Cr) R*, diluting with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Carry out the determination using the emission of chromium at 205.55 nm, the spectral background being taken as 205.50 nm.

Verify the absence of chromium in the hydrochloric acid used.

Extractable titanium. Not more than 1.0 ppm of extractable Ti, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluted with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable vanadium. Not more than 0.1 ppm of extractable V, determined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *vanadium standard solution (1 g/l V) R*, diluted with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Carry out the determination using the emission of vanadium at 292.40 nm, the spectral background being taken as 292.35 nm.

Verify the absence of vanadium in the hydrochloric acid used.

Extractable zinc. Not more than 1.0 ppm of extractable Zn, determined by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R*, diluted with *0.1 M hydrochloric acid*.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as a source of radiation and an air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Extractable heavy metals (*2.4.8*). Concentrate 50 ml of solution S3 to about 5 ml on a water-bath and dilute to 20.0 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (2.5 ppm). Prepare the standard using 2.5 ml of *lead standard solution (10 ppm Pb) R*.

Sulphated ash (*2.4.14*). Not more than 1.0 per cent, determined on 5.0 g. This limit does not apply to material that has been opacified with titanium dioxide.

SUPPLEMENTARY TESTS

These tests are to be carried out, in whole or in part, only if required by the stated composition of the material.

Phenolic antioxidants. Examine by liquid chromatography (*2.2.29*).

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase one of the three following mixtures:

  Mobile phase 1 at a flow rate of 2 ml/min: 30 volumes of *water R*, 70 volumes of *acetonitrile R*,

  Mobile phase 2 at a flow rate of 1.5 ml/min: 10 volumes of *water R*, 30 volumes of *tetrahydrofuran R*, 60 volumes of *acetonitrile R*,

  Mobile phase 3 at a flow rate of 1.5 ml/min: 5 volumes of *water R*, 45 volumes of *2-propanol R*, 50 volumes of *methanol R*,
- as detector a spectrophotometer set at 280 nm.

The chromatographic system must ensure the following:

- a resolution of not less than 8.0 between the peaks corresponding respectively to plastic additive 07 and plastic additive 08, with mobile phase 1,
- a resolution of not less than 2.0 between the peaks corresponding respectively to plastic additive 09 and plastic additive 10, with mobile phase 2,
- a resolution of not less than 2.0 between the peaks corresponding respectively to plastic additive 11 and plastic additive 12, with mobile phase 3.

Test solution S21. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue with 5.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S22. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue with 5.0 ml of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Of the following reference solutions, only prepare those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (b). Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (c). Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

Reference solution (d). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (e). Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (f). Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (g). Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (h). Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (i). Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

Reference solution (j). Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

If the substance to be examined contains plastic additive 07 and/or plastic additive 08, use mobile phase 1 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution and 20 µl of reference solution (a), and either 20 µl of reference solution (d) or (e), or 20 µl of reference solutions (d) and (e).

If the substance to be examined contains one or more of the following antioxidants:

- plastic additive 09,
- plastic additive 10,
- plastic additive 11,
- plastic additive 12,
- plastic additive 13,

use mobile phase 2 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (b) and 20 µl of the reference solutions of the antioxidants on the list above that are stated in the composition.

If the substance to be examined contains plastic additive 11 and/or plastic additive 12, use mobile phase 3 and inject 20 µl of test solution S22, 20 µl of the corresponding blank solution, 20 µl of reference solution (c), and either 20 µl of reference solution (i) or (j), or 20 µl of reference solutions (i) and (j).

In all cases record the chromatogram for 30 min; the chromatograms corresponding to test solutions S21 and S22 only show peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatograms corresponding to the blank solutions. The areas of the peaks of test solutions S21 and S22 are less than the areas of the corresponding peaks in the chromatograms obtained with reference solutions (d) to (j).

Non-phenolic antioxidants. Examine by thin-layer chromatography (*2.2.27*), using a *TLC silica gel GF_{254} plate R*.

Test solution S23. Evaporate 100 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue with 2 ml of *acidified methylene chloride R*.

Reference solution (k). Dissolve 60 mg of *plastic additive 14 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (l). Dissolve 60 mg of *plastic additive 15 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (m). Dissolve 60 mg of *plastic additive 16 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (n). Dissolve 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (o). Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Apply separately to the plate 20 µl of test solution S23, 20 µl of reference solution (o) and 20 µl of the reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined. Develop over a path of 18 cm using *hexane R*. Allow the plate to dry. Develop a second time over a path of 17 cm using *methylene chloride R*. Allow the plate to dry and examine in ultraviolet light at 254 nm. Spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10 min to 15 min. Any spots in the chromatogram obtained with test solution S23 are not more intense than the spots in the same locations in the chromatograms obtained with the reference solutions. The test is not valid unless the chromatogram obtained with reference solution (o) shows two clearly separated spots.

Amides and stearates. Examine by thin-layer chromatography (*2.2.27*), using 2 plates of the *TLC silica gel GF_{254} plate R* type.

Test solution. Use solution S23 described in the test for non-phenolic antioxidants.

Reference solution (p). Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in *methylene chloride R* and dilute to 10 ml with the same solvent.

Reference solution (q). Dissolve 40 mg of *plastic additive 20 CRS* in *methylene chloride R* and dilute to 20 ml with the same solvent.

Reference solution (r). Dissolve 40 mg of *plastic additive 21 CRS* in *methylene chloride R* and dilute to 20 ml with the same solvent.

Apply to each of the two plates 10 µl of solution S23. Apply 10 µl of reference solution (p) to the first and 10 µl each of reference solutions (q) and (r) to the second. Develop the first plate over a path of 10 cm using a mixture of 25 volumes of *ethanol R* and 75 volumes of *trimethylpentane R*. Allow the plate to dry in air. Spray with a 2 g/l solution of *dichlorophenolindophenol sodium salt R* in *ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots. Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S23 is identical in position (R_F about 0.5) but not more intense than the spot in the same position in the chromatogram obtained with reference solution (p).

Develop the second plate over a path of 13 cm using *hexane R*. Allow the plate to dry in air. Develop a second time over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry.

Spray with a 40 g/l solution of *phosphomolybdic acid R* in *ethanol R*. Heat in an oven at 120 °C until spots appear. Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with test solution S23 are identical in position (R_F about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (q) and (r).

01/2008:30107

3.1.7. POLY(ETHYLENE - VINYL ACETATE) FOR CONTAINERS AND TUBING FOR TOTAL PARENTERAL NUTRITION PREPARATIONS

DEFINITION

Poly(ethylene - vinyl acetate), complying with the following requirements, is suitable for the manufacture of containers and tubing for total parenteral nutrition preparations.

Poly(ethylene - vinyl acetate) is obtained by copolymerisation of mixtures of ethylene and vinyl acetate. This copolymer contains a defined quantity of not more than 25 per cent of vinyl acetate for material to be used for containers and not more than 30 per cent for material to be used for tubing.

PRODUCTION

A certain number of additives are added to the polymer in order to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the appended list which specifies for each product the maximum allowable content.

Poly(ethylene - vinyl acetate) may contain not more than three of the following antioxidants:

- butylhydroxytoluene (plastic additive 07) (not more than 0.125 per cent),
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09) (not more than 0.2 per cent),
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate (plastic additive 11) (not more than 0.2 per cent),
- tris(2,4-di-*tert*-butylphenyl) phosphite (plastic additive 12) (not more than 0.2 per cent),
- 2,2′,2″,6,6′,6″-hexa-*tert*-butyl-4,4′,4″-[(2,4,6-trimethyl-1,3,5-benzenetriyl)trismethylene]triphenol (plastic additive 10) (not more than 0.2 per cent).

It may also contain:

- oleamide (plastic additive 20) (not more than 0.5 per cent),
- erucamide (plastic additive 21) (not more than 0.5 per cent),
- calcium stearate or zinc stearate or a mixture of both (not more than 0.5 per cent),
- calcium carbonate or potassium hydroxide (not more than 0.5 per cent of each),
- colloidal silica (not more than 0.2 per cent).

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Beads, granules or, after transformation, translucent sheets or tubing of varying thickness or samples of finished objects, practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in methanol and in hexane, which dissolves, however, low molecular mass polymers. It burns with a blue flame. The temperature at which the substance softens changes with the vinyl acetate content; it decreases from about 100 °C for contents of a few per cent to about 70 °C for contents of 30 per cent.

IDENTIFICATION

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution obtained on a disc of sodium chloride and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (*2.2.24*). The spectrum obtained shows absorption maxima corresponding to vinyl acetate at the following positions: 1740 cm^{-1}, 1375 cm^{-1}, 1240 cm^{-1}, 1020 cm^{-1}, 610 cm^{-1}, and maxima corresponding to ethylene at the following positions: 2920 cm^{-1} to 2850 cm^{-1}, 1470 cm^{-1}, 1460 cm^{-1}, 1375 cm^{-1}, 730 cm^{-1}, 720 cm^{-1}. The spectrum obtained is, in addition, identical to the spectrum obtained with the type sample provided by the manufacturer. If the material to be examined is in the form of sheets, the spectrum may be determined directly on a cut piece of suitable size.

TESTS

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 2.0 g in a borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and heat under a reflux condenser with constant agitation for 90 min. Allow to cool to 60 °C and add 120 ml of *methanol R* to the flask with constant stirring. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsing mixture to the filtrate and dilute to 250 ml with the same mixture of solvents.

Solution S2. *Use within 4 h of preparation.* Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution S2 and filter the rest through a sintered-glass filter (16) (*2.1.2*).

Appearance of solution S2. Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 100 ml of solution S2 add 0.15 ml of *BRP indicator solution R*. Not more than 1.0 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S2 add 0.2 ml of *methyl orange solution R*. Not more than 1.5 ml of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*). At wavelengths from 220 nm to 340 nm, the absorbance of solution S2 is not greater than 0.2.

Reducing substances. To 20 ml of solution S2 add 1 ml of *dilute sulphuric acid R* and 20 ml of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using

0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 ml.

Amides and stearic acid. Examine by thin-layer chromatography (*2.2.27*), using 2 plates of the *TLC silica gel GF_{254} plate R* type.

Test solution. Evaporate 100 ml of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 ml of *acidified methylene chloride R*.

Reference solution (a). Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in 10 ml of *methylene chloride R*.

Reference solution (b). Dissolve 40 mg of *plastic additive 20 CRS* in 10 ml of *methylene chloride R*. Dilute 1 ml of the solution to 5 ml with *methylene chloride R*.

Reference solution (c). Dissolve 40 mg of *plastic additive 21 CRS* in 10 ml of *methylene chloride R*. Dilute 1 ml of the solution to 5 ml with *methylene chloride R*.

Apply separately 10 µl of each solution to the two plates.

Develop the first plate over a path of 10 cm using a mixture of 25 volumes of *ethanol R* and 75 volumes of *trimethylpentane R*. Allow the plate to dry. Spray with a 2 g/l solution of *dichlorophenolindophenol sodium salt R* in *ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots. Any spot corresponding to plastic additive 19 in the chromatogram obtained with the test solution is not more intense than the spot in the chromatogram obtained with reference solution (a).

Develop the second plate over a path of 13 cm using *hexane R*. Allow the plate to dry. Develop a second time over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry. Spray with a 40 g/l solution of *phosphomolybdic acid R* in *ethanol R*. Heat in an oven at 120 °C until spots appear. Any spots corresponding to plastic additive 21 or plastic additive 20 in the chromatogram obtained with the test solution are not more intense than the spots in the chromatograms obtained with reference solutions (b) and (c) respectively.

Phenolic antioxidants. Examine by liquid chromatography (*2.2.29*).

Test solution (a). Evaporate 50 ml of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Test solution (b). Evaporate 50 ml of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 ml of *methylene chloride R*.

Reference solution (a). Dissolve 25 mg of *butylhydroxytoluene CRS* (plastic additive 07), 40 mg of *plastic additive 10 CRS*, 40 mg of *plastic additive 09 CRS* and 40 mg of *plastic additive 11 CRS* in 10 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (b). Dissolve 40 mg of *plastic additive 11 CRS* and 40 mg of *plastic additive 12 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml to 50.0 ml with *methylene chloride R*.

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase at a flow rate of 1.5 ml/min one of the two following mixtures:

  Mobile phase 1: 10 volumes of *water R*, 30 volumes of *tetrahydrofuran R*, 60 volumes of *acetonitrile R*,

  Mobile phase 2: 5 volumes of *water R*, 45 volumes of *2-propanol R*, 50 volumes of *methanol R*,
- as detector a spectrophotometer set at 280 nm.

Using mobile phase 1, inject 20 µl of test solution (a) and 20 µl of reference solution (a). The chromatogram obtained with test solution (a) shows only principal peaks corresponding to the peaks in the chromatogram obtained with reference solution (a) with a retention time greater than 2 min.

The areas of the peaks in the chromatogram obtained with test solution (a) are not greater than those of the corresponding peaks in the chromatogram obtained with reference solution (a), except for the last peak eluted in the chromatogram obtained with reference solution (a).

The test is not valid unless, with mobile phase 1, the number of theoretical plates calculated for the peak corresponding to plastic additive 07 is at least 2500 and the resolution between the peaks corresponding to plastic additive 09 and plastic additive 10 is not less than 2.0.

If the chromatogram obtained with test solution (a) shows a peak with the same retention time as the last antioxidant eluted from reference solution (a), use mobile phase 2 as follows.

Inject 20 µl of test solution (b) and 20 µl of reference solution (b). The chromatogram obtained with test solution (b) shows only principal peaks corresponding to the peaks in the chromatogram obtained with reference solution (b) with a retention time greater than 3 min.

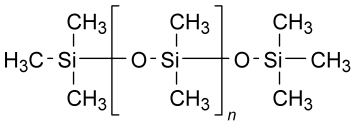
The areas of the peaks in the chromatogram obtained with test solution (b) are not greater than those of the corresponding peaks in the chromatogram obtained with reference solution (b).

The test is not valid unless the resolution between the peaks corresponding to plastic additive 11 and plastic additive 12 is at least 2.0.

Substances soluble in hexane. Place 5 g in a borosilicate-glass flask with a ground-glass neck. Add 50 ml of *hexane R*, fit a condenser and boil under reflux on a water-bath with constant stirring for 4 h. Cool in iced-water; a gel may form. Adapt a cooling jacket filled with iced water to a sintered-glass filter (16) (*2.1.2*) fitted with a device allowing pressure to be applied during filtration. Allow the filter to cool for 15 min. Filter the hexane solution applying a gauge pressure of 27 kPa and without washing the residue; the filtration time must not exceed 5 min. Evaporate 20 ml of the solution to dryness on a water-bath. Dry at 100 °C for 1 h. The mass of the residue is not greater than 40 mg (2 per cent) for copolymer to be used for containers and not greater than 0.1 g (5 per cent) for copolymer to be used for tubing.

Sulphated ash (*2.4.14*). Not more than 1.2 per cent, determined on 5.0 g.

ASSAY



Introduce 0.250 g to 1.000 g of the substance to be examined, according to the vinyl acetate content of the copolymer to be examined, into a 300 ml conical flask with a ground-glass neck containing a magnetic stirrer. Add 40 ml of *xylene R*. Boil under a reflux condenser with stirring for 4 h. Stirring continuously, allow to cool until precipitation begins before slowly adding 25.0 ml of *alcoholic potassium hydroxide solution R1*. Boil again under a reflux condenser with stirring for 3 h. Allow to cool with continued stirring, rinse the condenser with 50 ml of *water R* and add 30.0 ml of *0.05 M sulphuric acid* to the flask. Transfer the contents of the flask into a 400 ml beaker; rinse the flask with two quantities, each of 50 ml, of a 200 g/l solution of *anhydrous sodium sulphate R* and three quantities, each of 20 ml, of

water R and add all the rinsings to the beaker containing the initial solution. Titrate the excess sulphuric acid with *0.1 M sodium hydroxide*, determining the end-point potentiometrically (*2.2.20*). Carry out a blank titration.

1 ml of *0.05 M sulphuric acid* is equivalent to 8.609 mg of vinyl acetate.

01/2008:30108

3.1.8. SILICONE OIL USED AS A LUBRICANT

DEFINITION

Silicone oil used as a lubricant is a poly(dimethylsiloxane) obtained by hydrolysis and polycondensation of dichlorodimethylsilane and chlorotrimethylsilane. Different grades exist which are characterised by a number indicating the nominal viscosity placed after the name.

Silicone oil used as lubricants have a degree of polymerisation (n = 400 to 1200) such that their kinematic viscosities are nominally between 1000 $mm^2 \cdot s^{-1}$ and 30 000 $mm^2 \cdot s^{-1}$.

CHARACTERS

Clear, colourless liquids of various viscosities, practically insoluble in water and in methanol, miscible with ethyl acetate, with methyl ethyl ketone and with toluene, very slightly soluble in ethanol.

IDENTIFICATION

A. It is identified by its kinematic viscosity at 25 °C (see Tests).

B. Examine by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *silicone oil CRS*. The region of the spectrum from 850 cm^{-1} to 750 cm^{-1} is not taken into account since it may show slight differences depending on the degree of polymerisation.

C. Heat 0.5 g in a test-tube over a small flame until white fumes begin to appear. Invert the tube over a second tube containing 1 ml of a 1 g/l solution of *chromotropic acid, sodium salt R* in *sulphuric acid R* so that the fumes reach the solution. Shake the second tube for about 10 s and heat on a water-bath for 5 min. The solution is violet.

D. In a platinum crucible, prepare the sulphated ash (*2.4.14*) using 50 mg. The residue is a white powder that gives the reaction of silicates (*2.3.1*).

TESTS

Acidity. To 2.0 g add 25 ml of a mixture of equal volumes of *ethanol R* and *ether R*, previously neutralised to 0.2 ml of *bromothymol blue solution R1* and shake. Not more than 0.15 ml of *0.01 M sodium hydroxide* is required to change the colour of the solution to blue.

Viscosity (*2.2.10*). Determine the dynamic viscosity at 25 °C. Calculate the kinematic viscosity taking the relative density to be 0.97. The kinematic viscosity is not less than 95 per cent and not more than 105 per cent of the nominal viscosity stated on the label.

Mineral oils. Place 2 ml in a test-tube and examine in ultraviolet light at 365 nm. The fluorescence is not more intense than that of a solution containing 0.1 ppm of *quinine sulphate R* in *0.005 M sulphuric acid* examined in the same conditions.

Phenylated compounds. The refractive index (*2.2.6*) is not greater than 1.410.

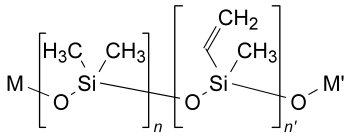
Heavy metals. Mix 1.0 g with *methylene chloride R* and dilute to 20 ml with the same solvent. Add 1.0 ml of a freshly prepared 0.02 g/l solution of *dithizone R* in *methylene chloride R*, 0.5 ml of *water R* and 0.5 ml of a mixture of 1 volume of *dilute ammonia R2* and 9 volumes of a 2 g/l solution of *hydroxylamine hydrochloride R*. At the same time, prepare a standard as follows: to 20 ml of *methylene chloride R* add 1.0 ml of a freshly prepared 0.02 g/l solution of *dithizone R* in *methylene chloride R*, 0.5 ml of *lead standard solution (10 ppm Pb) R* and 0.5 ml of a mixture of 1 volume of *dilute ammonia R2* and 9 volumes of a 2 g/l solution of *hydroxylamine hydrochloride R*. Immediately shake each solution vigorously for 1 min. Any red colour in the test solution is not more intense than that in the standard (5 ppm).

Volatile matter. Not more than 2.0 per cent, determined on 2.00 g by heating in an oven at 150 °C for 24 h. Carry out the test using a dish 60 mm in diameter and 10 mm deep.

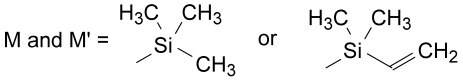
LABELLING

The label indicates the nominal viscosity by a number placed after the name of the product. The label also states that the contents are to be used as a lubricant.

01/2008:30109



3.1.9. SILICONE ELASTOMER FOR CLOSURES AND TUBING



DEFINITION

Silicone elastomer complying with the following requirements is suitable for the manufacture of closures and tubing.

Silicone elastomer is obtained by cross-linking a linear polysiloxane constructed mainly of dimethylsiloxy units with small quantities of methylvinylsiloxy groups; the chain ends are blocked by trimethylsiloxy or dimethylvinylsiloxy groups.

The general formula of the polysiloxane is:

The cross-linking is carried out in the hot state either with:

– 2,4-dichlorobenzoyl peroxide for extruded products,

– 2,4-dichlorobenzoyl peroxide or dicumyl peroxide or *OO*-(1,1-dimethylethyl) *O*-isopropyl monoperoxycarbonate or 2,5-bis[(1,1-dimethylethyl)dioxy]-2,5-dimethylhexane for moulded products,

or

– by hydrosilylation by means of polysiloxane with -SiH groups using platinum as a catalyst.

In all cases, appropriate additives are used such as silica and sometimes small quantities of organosilicon additives (α,ω-dihydroxypolydimethylsiloxane).

CHARACTERS

A transparent or translucent material, practically insoluble in organic solvents, some of which, for example cyclohexane, hexane and methylene chloride, cause a reversible swelling of the material.

IDENTIFICATION

A. Examine by infrared absorption spectrophotometry recording the spectrum by the multiple reflection method for solids (*2.2.24*), comparing with the spectrum obtained with *silicone elastomer CRS*.

B. Heat 1.0 g in a test-tube over a small flame until white fumes begin to appear. Invert the tube over a second tube containing 1 ml of a 1 g/l solution of *chromotropic acid, sodium salt R* in *sulphuric acid R* so that the fumes reach the solution. Shake the second tube for about 10 s and heat on a water-bath for 5 min. The solution is violet.

C. 50 mg of the residue of combustion gives the reaction of silicates (*2.3.1*).

TESTS

If necessary, cut the material into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S. Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water R* and boil under a reflux condenser for 5 h. Allow to cool and decant the solution.

Appearance of solution. Solution S is clear (*2.2.1*).

Acidity or alkalinity. To 100 ml of solution S add 0.15 ml of *bromothymol blue solution R1*. Not more than 2.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To a further 100 ml of solution S, add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Relative density (*2.2.5*). 1.05 to 1.25, determined using a density bottle with *ethanol R* as the immersion liquid.

Reducing substances. To 20 ml of solution S add 1 ml of *dilute sulphuric acid R* and 20 ml of *0.002 M potassium permanganate*. Allow to stand for 15 min. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate* using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration using 20 ml of *water R* instead of solution S. The difference between the titration volumes is not more than 1.0 ml.

Substances soluble in hexane. Evaporate 25 ml of the solution obtained in the test for phenylated compounds in a glass evaporating dish on a water-bath and dry in an oven at 100 °C to 105 °C for 1 h. The residue weighs not more than 15 mg (3 per cent).

Phenylated compounds. Place 2.0 g in a borosilicate-glass flask with a ground-glass neck and add 100 ml of *hexane R*. Boil under a reflux condenser for 4 h. Cool, then filter rapidly through a sintered-glass filter (16) (*2.1.2*). Collect the filtrate and close the container immediately to avoid evaporation. At wavelengths from 250 nm to 340 nm, the absorbance (*2.2.25*) is not greater than 0.4.

Mineral oils. Place 2 g in a 100 ml conical flask containing 30 ml of a mixture of 5 volumes of *ammonia R* and 95 volumes of *pyridine R*. Allow to stand for 2 h, shaking frequently. Decant the pyridine solution and examine in ultraviolet light at 365 nm. The fluorescence is not greater than that of a solution containing 1 ppm of *quinine sulphate R* in *0.005 M sulphuric acid* examined in the same conditions.

Volatile matter. Weigh 10.0 g of the substance previously stored for 48 h in a desiccator over *anhydrous calcium chloride R*. Heat in an oven at 200 °C for 4 h, allow to cool in a desiccator and weigh again. For silicone elastomer prepared using peroxides, the volatile matter is not greater than 0.5 per cent. For silicone elastomer prepared using platinum, the volatile matter is not greater than 2.0 per cent.

Silicone elastomer prepared using peroxides complies with the following additional test:

Residual peroxides. Place 5 g in a borosilicate-glass flask, add 150 ml of *methylene chloride R* and close the flask. Stir with a mechanical stirrer for 16 h. Filter rapidly, collecting the filtrate in a flask with a ground-glass neck. Replace the air in the container with *oxygen-free nitrogen R*, introduce 1 ml of a 200 g/l solution of *sodium iodide R* in *anhydrous acetic acid R*, close the flask, shake thoroughly and allow to stand protected from light for 30 min. Add 50 ml of *water R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not greater than 2.0 ml (0.08 per cent calculated as dichlorobenzoyl peroxide).

Silicone elastomer prepared using platinum complies with the following additional test:

Platinum. In a quartz crucible, ignite 1.0 g of the material to be examined, raising the temperature gradually until a white residue is obtained. Transfer the residue to a graphite crucible. To the quartz crucible add 10 ml of a freshly prepared mixture of 1 volume of *nitric acid R* and 3 volumes of *hydrochloric acid R*, heat on a water-bath for 1 min to 2 min and transfer to the graphite crucible. Add 5 mg of *potassium chloride R* and 5 ml of *hydrofluoric acid R* and evaporate to dryness on a water-bath. Add 5 ml of *hydrofluoric acid R* and evaporate to dryness again; repeat this operation twice. Dissolve the residue in 5 ml of *1 M hydrochloric acid*, warming on a water-bath. Allow to cool and add the solution to 1 ml of a 250 g/l solution of *stannous chloride R* in *1 M hydrochloric acid*, rinse the graphite crucible with a few millilitres of *1 M hydrochloric acid* and dilute to 10.0 ml with the same acid. Prepare simultaneously a standard as follows: to 1 ml of a 250 g/l solution of *stannous chloride R* in *1 M hydrochloric acid* add 1.0 ml of *platinum standard solution (30 ppm Pt) R* and dilute to 10.0 ml with *1 M hydrochloric acid*. The colour of the test solution is not more intense than that of the standard (30 ppm).

LABELLING

The label states whether the material was prepared using peroxides or platinum.

01/2008:30110 corrected 6.0

3.1.10. MATERIALS BASED ON NON-PLASTICISED POLY(VINYL CHLORIDE) FOR CONTAINERS FOR NON-INJECTABLE, AQUEOUS SOLUTIONS

DEFINITION

Materials based on non-plasticised poly(vinyl chloride) that comply with the following specifications are suitable for the manufacture of containers for non-injectable aqueous solutions. They may also be used for solid forms for oral administration and in some cases, subject to special studies on the compatibility of the container with its contents, these materials may be suitable for the preparation of containers for suppositories. They consist of one or more poly(vinyl chloride/vinyl acetate) or of a mixture of poly(vinyl chloride) and poly(vinyl acetate) or of poly(vinyl chloride).

They contain not more than 1 ppm of vinyl chloride.

The chlorine content expressed in poly(vinyl chloride) is not less than 80 per cent.

They may contain not more than 15 per cent of copolymers based on acrylic and/or methacrylic acids and/or their esters, and/or on styrene and/or butadiene.

PRODUCTION

Materials based on non-plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test:

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (*2.2.28*), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject these 25 ml of vinyl chloride slowly into the vial, shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into five of the vials. The six solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamide R* and 5 per cent *m/m* of *macrogol 400 R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 45 °C, that of the injection port at 100 °C and that of the detector at 150 °C.

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

In order to obtain the required mechanical and stability characteristics, materials based on non-plasticised poly(vinyl chloride) may contain:

- not more than 8 per cent of epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6,
- not more than 1.5 per cent of calcium salt or zinc salts of aliphatic fatty acids with more than seven carbon atoms or not more than 1.5 per cent of their mixture,
- not more than 1.5 per cent of liquid paraffin,
- not more than 1.5 per cent of waxes,
- not more than 2 per cent of hydrogenated oils or esters of aliphatic fatty acids,
- not more than 1.5 per cent of macrogol esters,
- not more than 1.5 per cent of sorbitol,
- not more than 1 per cent of 2,4-dinonylphenyl phosphite, or di(4-nonylphenyl) phosphite or tris(nonylphenyl) phosphite.

They may contain one of the following groups of stabilisers:

- not more than 0.25 per cent of tin as di(isooctyl) 2,2′-[(dioctylstannylene)bis(thio)]diacetate containing about 27 per cent of tri(isooctyl) 2,2′,2″-[(monooctylstannylidyne)tris(thio)]triacetate,
- not more than 0.25 per cent of tin as a mixture containing not more than 76 per cent of di(isooctyl) 2,2′-[(dimethylstannylene)bis(thio)]diacetate and not more than 85 per cent of tri(isooctyl) 2,2′,2″-[(monomethylstannylidyne)tris(thio)]triacetate; (isooctyl is e.g. 2-ethylhexyl),
- not more than 1 per cent of 1-phenyleicosane-1,3-dione (benzoylstearoylmethane) or 2-(4-dodecylphenyl)indole or didodecyl 1,4-dihydropyridine-2,6-dimethyl-3,5-dicarboxylate or 1 per cent of a mixture of two of these.

They may contain a colorant or pigment.

They may be opacified by titanium dioxide.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules, sheets of varying thicknesses or samples taken from finished objects, insoluble in water, soluble in tetrahydrofuran, slightly soluble in

methylene chloride, insoluble in ethanol. They burn with an orange-yellow flame edged with green, giving off thick black smoke.

IDENTIFICATION

Dissolve the residue (A) (see Tests: solution S2) in 5 ml of *tetrahydrofuran R*. Apply a few drops of the solution to a sodium chloride plate and evaporate to dryness in an oven at 100 °C to 105 °C. Examine by infrared absorption spectrophotometry (*2.2.24*). The material to be examined shows absorption maxima at 2975 cm^{-1}, 2910 cm^{-1}, 2865 cm^{-1}, 1430 cm^{-1}, 1330 cm^{-1}, 1255 cm^{-1}, 690 cm^{-1}, 615 cm^{-1}. In addition, the spectrum obtained is identical to that of the material selected for the type sample.

TESTS

If necessary, cut the material into pieces with a maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 25 g in a borosilicate-glass flask. Add 500 ml of *water R* and cover the neck of the flask with aluminium foil or a borosilicate-glass beaker. Heat in an autoclave for 121 ± 2 °C for 20 min. Allow to cool and allow the solids to settle.

Solution S2. Dissolve 5.0 g in 80 ml of *tetrahydrofuran R* and dilute to 100 ml with the same solvent. Filter if necessary (the solution may remain opalescent). Dilute 20 ml of the solution and add dropwise with gentle shaking 70 ml of *alcohol R*. Cool in ice for 1 h. Filter or centrifuge. Wash the residue A with *alcohol R* and add the washings to the filtrate or the centrifugation liquid. Dilute to 100 ml with *alcohol R*.

Solution S3. Place 5 g in a borosilicate-glass flask with a ground-glass neck. Add 100 ml of *0.1 M hydrochloric acid* and boil under a reflux condenser for 1 h. Allow to cool and allow the solids to settle.

Appearance of solution S1. Solution S1 is not more opalescent than reference suspension II (*2.2.1*) and is colourless (*2.2.2, Method II*).

Absorbance of solution S1 (*2.2.25*). Evaporate to dryness 100 ml of solution S1. Dissolve the residue in 5 ml of *hexane R*. Filter if necessary through a filter previously rinsed with *hexane R*. At wavelengths from 250 nm to 310 nm, the absorbance of the filtrate is not greater than 0.25.

Absorbance of solution S2 (*2.2.25*). At wavelengths from 250 nm to 330 nm, the absorbance of solution S2 is not greater than 0.2 for tin-stabilised materials or 0.4 for other materials.

Extractable barium. Examine by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S3.

Reference solution. A solution containing 0.1 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Examined at 455.40 nm, the emission of the test solution is not greater than that of the reference solution (2.0 ppm).

Extractable cadmium. Examine by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Solution S3.

Reference solution. A solution containing 0.03 ppm of cadmium prepared by diluting *cadmium standard solution (0.1 per cent Cd) R* with *0.1 M hydrochloric acid*.

Verify the absence of cadmium in the hydrochloric acid used.

Examined at 228.8 nm, the absorbance of the test solution is not greater than that of the reference solution (0.6 ppm).

Tin-stabilised materials. To 0.10 ml of solution S2 in a test tube add 0.05 ml of *1 M hydrochloric acid*, 0.5 ml of *potassium iodide solution R* and 5 ml of *alcohol R*. Mix thoroughly and wait for 5 min. Add 9 ml of *water R* and 0.1 ml of a 5 g/l solution of *sodium sulphite R* and mix thoroughly. Add 1.5 ml of *dithizone solution R* freshly diluted one-hundred-fold with *methylene chloride R*, shake for 15 s and allow to stand for 2 min. At the same time prepare a reference solution in the same manner using 0.1 ml of tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution (0.25 per cent of Sn). The greenish-blue colour of dithizone solution turns pink in the presence of tin.

Tin stock solution. Dilute 81 mg of *plastic additive 23 CRS* in a 100 ml volumetric flask to 100 ml with *tetrahydrofuran R*.

Tin standard solution. Dilute 20 ml of tin stock solution in a 100 ml volumetric flask to 100 ml with *alcohol R*.

Non-tin stabilised materials. To 5 ml of solution S2 in a test tube add 0.05 ml of *1 M hydrochloric acid* and 0.5 ml of *potassium iodide solution R*. Mix thoroughly and wait for 5 min. Add 9 ml of *water R* and 0.1 ml of a 5 g/l solution of *sodium sulphite R* and mix thoroughly. If the solution obtained is not colourless, add the sodium sulphite solution in 0.05 ml fractions. Add 1.5 ml of *dithizone solution R* freshly diluted one hundred times with *methylene chloride R*, shake for 15 s and allow to stand for 2 min. At the same time prepare a standard in the same manner using 0.05 ml of tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution (25 ppm of Sn).

Extractable heavy metals (*2.4.8*). 12 ml of solution S3 complies with limit test A for heavy metals (20 ppm). Prepare the standard using 10 ml of *lead standard solution (1 ppm Pb) R*.

Extractable zinc. Examine by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Solution S3 diluted ten times with *water R*.

Reference solution. A solution containing 0.50 ppm of zinc prepared by dilution of *zinc standard solution (5 mg/ml Zn) R* with *0.01 M hydrochloric acid*.

Verify the absence of zinc in the hydrochloric acid used.

Examined at 214.0 nm, the absorbance of the test solution is not greater than that of the reference solution (1.00×10^2 ppm).

Sulphated ash (*2.4.14*). Not more than 1.0 per cent, determined on 1.0 g. When the materials are opacified using titanium dioxide, the content of sulphated ash does not exceed 4.0 per cent.

ASSAY

Carry out the oxygen-flask method (*2.5.10*) using 50.0 mg of the substance to be examined. Absorb the combustion products in 20 ml of *1 M sodium hydroxide*. To the solution obtained add 2.5 ml of *nitric acid R*, 10.0 ml of *0.1 M silver nitrate*, 5 ml of *ferric ammonium sulphate solution R2* and 1 ml of *dibutyl phthalate R*. Titrate with *0.05 M ammonium thiocyanate* until a reddish-yellow colour is obtained. Carry out a blank titration.

1 ml of *0.1 M silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

01/2008:30111 corrected 6.0

3.1.11. MATERIALS BASED ON NON-PLASTICISED POLY(VINYL CHLORIDE) FOR CONTAINERS FOR DRY DOSAGE FORMS FOR ORAL ADMINISTRATION

DEFINITION

Materials based on non-plasticised poly(vinyl chloride) for containers for dry dosage forms for oral administration are suitable for the manufacture of sheets or containers.

They consist of one or more poly(vinyl chloride/vinyl acetate) or of a mixture of poly(vinyl chloride) and poly(vinyl acetate) or of poly(vinyl chloride).

They contain not more than 1 ppm of vinyl chloride.

The chlorine content expressed in poly(vinyl chloride) is not less than 80 per cent.

They may contain not more than 15 per cent of copolymers based on acrylic and/or methacrylic acids and/or their esters, and/or on styrene and/or butadiene.

PRODUCTION

Materials based on non-plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test for vinyl chloride.

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (*2.2.28*), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject these 25 ml of vinyl chloride slowly into the vial, shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into 5 of the vials. The 6 solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamide R* and 5 per cent *m/m* of *macrogol 400 R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 45 °C, that of the injection port at 100 °C and that of the detector at 150 °C.

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

Additives

In order to obtain the required mechanical and stability characteristics, materials based on non-plasticised poly(vinyl chloride) may contain:

- not more than 2 per cent of epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6 for tin-stabilised materials,
- not more than 3 per cent of epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6 for non-tin-stabilised materials,
- not more than 1.5 per cent of calcium, magnesium or zinc salts of aliphatic fatty acids with more than 7 carbon atoms or not more than 1.5 per cent of their mixture,
- not more than 4 per cent of waxes,
- not more than 1.5 per cent of liquid paraffin,
- not more than 2 per cent of hydrogenated oils or esters of aliphatic fatty acids,
- not more than 4 per cent for the percentage sum of the 3 lubricants above,
- not more than 1.5 per cent of macrogol esters,
- not more than 1.5 per cent of sorbitol,
- not more than 1 per cent of 2,4-dinonylphenyl phosphite, or di(4-nonylphenyl) phosphite or tris(nonylphenyl) phosphite,
- not more than 1 per cent of calcium carbonate,
- not more than 1 per cent of silica.

They may contain one of the following groups of stabilisers:

- not more than 0.25 per cent of tin as di(isooctyl) 2,2′-[(dioctylstannylene)bis(thio)]diacetate containing about 27 per cent of tri(isooctyl) 2,2′2″-[(monooctylstannylidyne)tris(thio)]triacetate,
- not more than 0.25 per cent of tin as a mixture containing not more than 76 per cent of di(isooctyl) 2,2′-[(dimethylstannylene)bis(thio)]diacetate and not more than 85 per cent of tri(isooctyl) 2,2′,2″-[(monomethylstannylidyne)tris(thio)]triacetate; (isooctyl is e.g. 2-ethylhexyl),
- not more than 1 per cent of 1-phenyleicosane-1,3-dione (benzoylstearoylmethane).

They may contain a colorant or pigment.

They may be opacified by titanium dioxide.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules, sheets of varying thicknesses or samples taken from finished objects, insoluble in water, soluble in tetrahydrofuran, slightly soluble in methylene chloride, insoluble in ethanol. They burn with an orange-yellow flame edged with green, giving off thick black smoke.

IDENTIFICATION

Dissolve residue A (see Tests: solution S2) in 5 ml of *tetrahydrofuran R*. Apply a few drops of the solution to a sodium chloride plate and evaporate to dryness in an oven at 100-105 °C. Examine by infrared absorption spectrophotometry (*2.2.24*). The material to be examined shows absorption maxima at 2975 cm^{-1}, 2910 cm^{-1}, 2865 cm^{-1}, 1430 cm^{-1}, 1330 cm^{-1}, 1255 cm^{-1}, 690 cm^{-1}, 615 cm^{-1}. In addition, the spectrum obtained is identical to that of the material selected for the type sample.

TESTS

If necessary, cut the material into pieces with a maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 25 g in a borosilicate glass flask. Add 500 ml of *water R* and cover the neck of the flask with aluminium foil or a borosilicate glass beaker. Heat in an autoclave for 121 ± 2 °C for 20 min. Allow to cool and allow the solids to settle.

Solution S2. Dissolve 5.0 g in 80 ml of *tetrahydrofuran R* and dilute to 100 ml with the same solvent. Filter if necessary (the solution may remain opalescent). Dilute 20 ml of the solution and add dropwise with gentle shaking 70 ml of *alcohol R*. Cool in ice for 1 h. Filter or centrifuge (residue A). Wash residue A with *alcohol R* and add the washings to the filtrate or the centrifugation liquid. Dilute to 100 ml with *alcohol R*.

Solution S3. Place 5 g in a borosilicate-glass flask with a ground-glass neck. Add 100 ml of *0.1 M hydrochloric acid* and boil under a reflux condenser for 1 h. Allow to cool and allow the solids to settle.

Appearance of solution S1. Solution S1 is not more opalescent than reference suspension II (*2.2.1*) and is colourless (*2.2.2, Method II*).

Absorbance of solution S1 (*2.2.25*). Evaporate to dryness 100 ml of solution S1. Dissolve the residue in 5 ml of *hexane R*. Filter if necessary through a filter previously rinsed with *hexane R*. At wavelengths from 250 nm to 310 nm, the absorbance of the filtrate is not greater than 0.3.

Absorbance of solution S2 (*2.2.25*). For material that does not contain 1-phenyleicosane-1,3-dione, at wavelengths from 250 nm to 330 nm, the absorbance of solution S2 is not greater than 0.5. For material that contains 1-phenyleicosane-1,3-dione, at wavelengths from 250 nm to 330 nm, the absorbance of a tenfold dilution of solution S2 in *alcohol R* is not greater than 0.4.

Tin-stabilised materials. To 0.10 ml of solution S2 in a test tube add 0.05 ml of *1 M hydrochloric acid*, 0.5 ml of *potassium iodide solution R* and 5 ml of *alcohol R*. Mix thoroughly and wait for 5 min. Add 9 ml of *water R* and 0.1 ml of a 5 g/l solution of *sodium sulphite R* and mix thoroughly. Add 1.5 ml of *dithizone solution R* freshly diluted one-hundred-fold with *methylene chloride R*, shake for 15 s and allow to stand for 2 min. At the same time prepare a reference solution in the same manner using 0.1 ml of tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution (0.25 per cent Sn). The greenish-blue colour of dithizone solution turns pink in the presence of tin.

Tin stock solution. Dilute 81 mg of *plastic additive 23 CRS* in a 100 ml volumetric flask to 100 ml with *tetrahydrofuran R*.

Tin standard solution. Dilute 20 ml of tin stock solution in a 100 ml volumetric flask to 100 ml with *alcohol R*.

Non tin-stabilised materials. To 5 ml of solution S2 in a test tube add 0.05 ml of *1 M hydrochloric acid* and 0.5 ml of *potassium iodide solution R*. Mix thoroughly and wait for 5 min. Add 9 ml of *water R* and 0.1 ml of a 5 g/l solution of *sodium sulphite R* and mix thoroughly. If the solution obtained is not colourless, add the sodium sulphite solution in 0.05 ml fractions. Add 1.5 ml of *dithizone solution R* freshly diluted 100 times with *methylene chloride R*, shake for 15 s and allow to stand for 2 min. At the same time prepare a standard in the same manner using 0.05 ml of tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution (25 ppm of Sn).

Extractable heavy metals (*2.4.8*). 12 ml of solution S3 complies with limit test A (20 ppm). Prepare the standard using 10 ml of *lead standard solution (1 ppm Pb) R*.

Extractable zinc. Examine by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Solution S3 diluted 10 times with *water R*.

Reference solution. A solution containing 0.50 ppm of zinc prepared by dilution of *zinc standard solution (5 mg/ml Zn) R* with *0.01 M hydrochloric acid*.

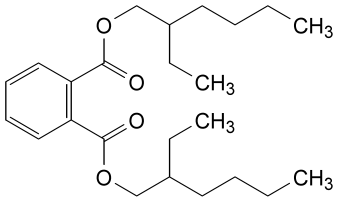
Verify the absence of zinc in the hydrochloric acid used.

Examined at 214.0 nm, the absorbance of the test solution is not greater than that of the reference solution (1.00×10^2 ppm).

Sulphated ash (*2.4.14*). Not more than 1.0 per cent, determined on 1.0 g. When the materials are opacified using titanium dioxide, the content of sulphated ash does not exceed 4.0 per cent.

ASSAY

Carry out the oxygen-flask method (*2.5.10*) using 50.0 mg of the substance to be examined. Absorb the combustion products in 20 ml of *1 M sodium hydroxide*. To the solution obtained add 2.5 ml of *nitric acid R*, 10.0 ml of *0.1 M silver nitrate*, 5 ml of *ferric ammonium sulphate solution R2* and 1 ml of *dibutyl phthalate R*. Titrate with *0.05 M ammonium thiocyanate* until a reddish-yellow colour is obtained. Carry out a blank titration.



1 ml of *0.1 M silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

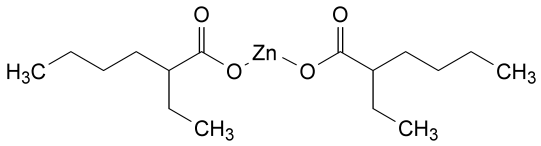
3.1.13. PLASTIC ADDITIVES

NOTE: the nomenclature given first is according to the IUPAC rules. The synonym given in bold corresponds to the name given in the texts of Chapter 3. The synonym corresponding to the rules of the texts of "Chemical Abstracts" is also given.

add01. $C_{24}H_{38}O_4$. [117-81-7]. PM RN 74640.

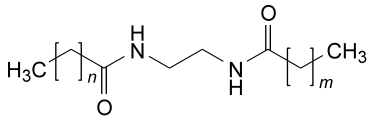


(2*RS*)-2-ethylhexyl benzene-1,2-dicarboxylate

synonyms: — **di(2-ethylhexyl) phthalate,**

— 1,2-benzenedicarboxylic acid, bis(2-ethylhexyl) ester.

add02. $C_{16}H_{30}O_4Zn$. [136-53-8]. PM RN 54120.



zinc (2*RS*)-2-ethylhexanoate

synonyms: — **zinc octanoate,**

— 2-ethylhexanoic acid, zinc salt (2:1),

— zinc 2-ethylcaproate.

add03. [05518-18-3]/[00110-30-5]. PM RN 53440/53520.

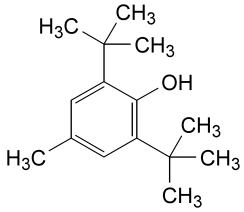
N,N′-ethylenedialcanamide (with *n* and *m* = 14 or 16)

synonyms: — ***N,N*′-diacylethylenediamines,**

— *N,N*′-diacylethylenediamine (in this context acyl means in particular palmitoyl and stearoyl).

add04. [8013-07-8]. PM RN 88640.

epoxidised soya oil



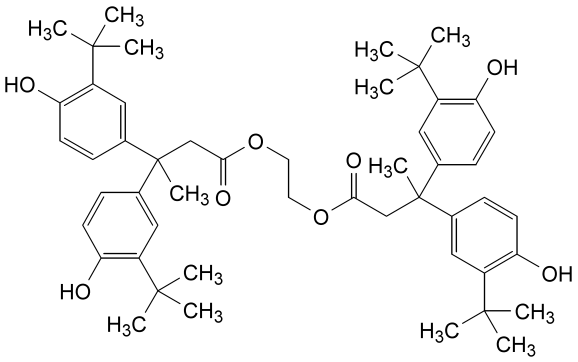
add05. [8016-11-3]. PM RN 64240.

epoxidised linseed oil

add06. [57455-37-5](TSCA)/[101357-30-6] (EINECS)/Pigment blue 29 (CI 77007)

ultramarine blue

add07. $C_{15}H_{24}O$. [128-37-0] PM RN 46640.



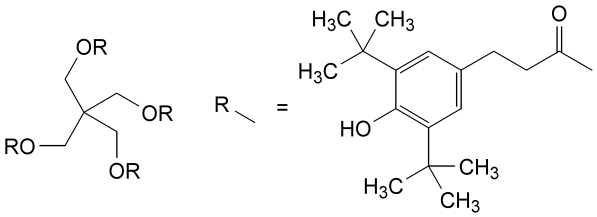
2,6-bis(1,1-dimethylethyl)-4-methylphenol

synonyms: — **butylhydroxytoluene,**

— 2,6-bis(1,1-dimethylethyl)-4-methylphenol,

— 2,6-di-*tert*-butyl-4-methylphenol.

add08. $C_{50}H_{66}O_8$. [32509-66-3]. PM RN 53670.



ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate]

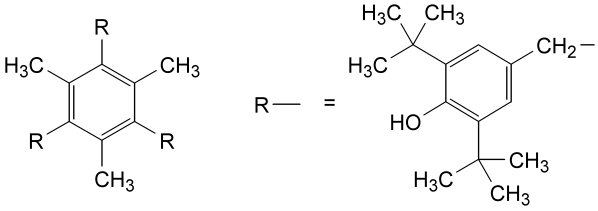
synonyms: — **ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate],**

— butanoic acid, 3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]-, 1,2-ethanediyl ester,

— ethylene bis[3,3-bis(3-*tert*-butyl-4-hydroxyphenyl)butyrate].

add09. $C_{73}H_{108}O_{12}$. [6683-19-8]. PM RN 71680.

methanetetryltetramethyl tetrakis[3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]propanoate]



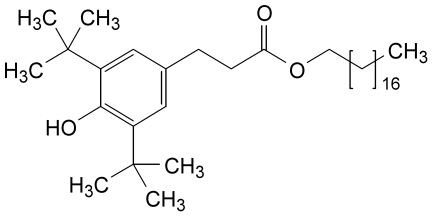
synonyms: — **pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate],**

— 2,2-bis[[[3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]propanoyl]oxy]methyl]propane-1,3-diyl 3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]propanoate,

— benzenepropanoic acid, 3,5-bis(1,1-dimethylethyl)-4-hydroxy-2,2-bis(hydroxymethyl)propane-1,3-diol ester (4:1),

— 2,2-bis(hydroxymethyl)propane-1,3-diol tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate].

add10. $C_{54}H_{78}O_3$. [1709-70-2]. PM RN 95200.



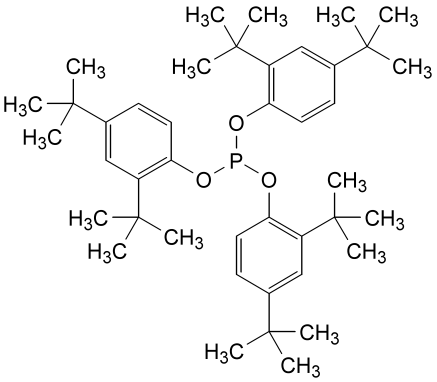
4,4′,4″-[(2,4,6-trimethylbenzene-1,3,5-triyl)tris(methylene)]tris[2,6-bis(1,1-dimethylethyl)phenol]

synonyms: **— 2,2′,2″,6,6′,6″-hexa-*tert*-butyl-4,4′,4″-[(2,4,6-trimethyl- 1,3,5-benzenetriyl)trismethylene]triphenol,**

— 1,3,5-tris[3,5-di-*tert*-butyl-4-hydroxybenzyl]-2,4,6-trimethylbenzene,

— phenol,4,4′,4″-[(2,4,6-trimethyl-1,3,5-benzenetriyl)tris(methylene)]tris[2,6-bis(1,1-dimethylethyl)-.

add11. $C_{35}H_{62}O_3$. [2082-79-3]. PM RN 68320.

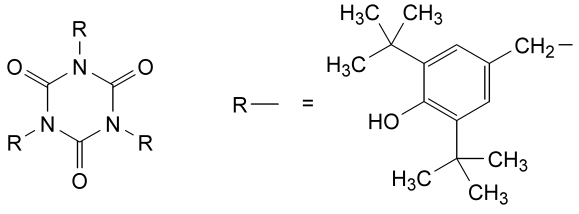


octadecyl 3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]propanoate

synonyms: **— octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate,**

— propanoic acid, 3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]-, octadecyl ester.

add12. $C_{42}H_{63}O_3P$. [31570-04-4]. PM RN 74240.



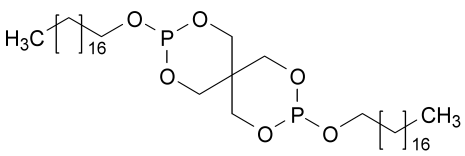
tris[2,4-bis(1,1-dimethylethyl)phenyl] phosphite

synonyms: **— tris(2,4-di-*tert*-butylphenyl) phosphite,**

— phenol, 2,4-bis(1,1-dimethylethyl)-, phosphite (3:1),

— 2,4-bis(1,1-dimethylethyl)phenyl, phosphite.

add13. $C_{48}H_{69}N_3O_6$. [27676-62-6]. PM RN 95360.

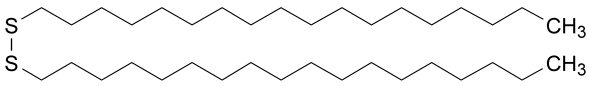


1,3,5-tris[3,5-bis(1,1-dimethylethyl)-4-hydroxybenzyl]-1,3,5-triazine-2,4,6(1*H*,3*H*,5*H*)-trione

synonyms: **— 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-*s*-triazine-2,4,6(1*H*,3*H*,5*H*)-trione,**

— 1,3,5-triazine-2,4,6(1*H*,3*H*,5*H*)-trione, 1,3,5-tris[[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]methyl]-.

add14. $C_{41}H_{82}O_6P_2$. [3806-34-6]. PM RN 50080.

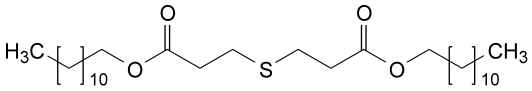


3,9-bis(octadecyloxy)-2,4,8,10-tetraoxa-3,9-diphosphaspiro[5.5]undecane

synonyms: **— 2,2′-bis(octadecyloxy)-5,5′-spirobi[1,3,2-dioxaphosphinane],**

— 2,4,8,10-tetraoxa-3,9-diphosphaspiro[5.5]undecane, 3,9-bis(octadecyloxy)-.

add15. $C_{36}H_{74}S_2$. [2500-88-1]. PM RN 49840.



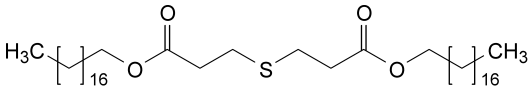
1,1′-disulphanediyldioctadecane

synonyms: **— dioctadecyl disulphide,**

— octadecane, 1,1′-dithio-.

add16. $C_{30}H_{58}O_4S$. [123-28-4]. PM RN 93120.

didodecyl 3,3′-sulphanediyldipropanoate



synonyms: **— didodecyl 3,3′-thiodipropionate,**

— didodecyl 3,3′-sulfanediyldipropanoate,

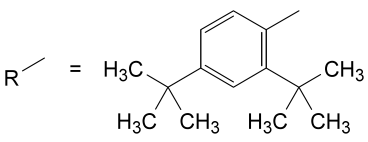
— propanoic acid, 3,3′-thiobis-, dodecyl diester,

— lauryl thiodipropionate.

add17. $C_{42}H_{82}O_4S$. [693-36-7]. PM RN 93280.

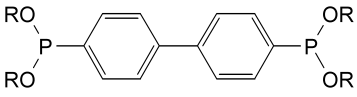
dioctadecyl 3,3′-sulphanediyldipropanoate

synonyms: **— dioctadecyl 3,3′-thiodipropionate,**



— dioctadecyl 3,3′-sulfanediyldipropanoate,

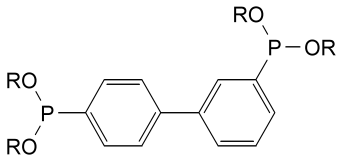
— propanoic acid, 3,3′-thiobis-, octadecyl diester,



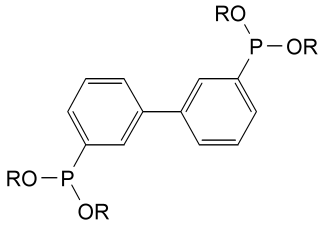
— stearyl thiodipropionate.

add18. [119345-01-6]. PM RN 92560.

mixture of seven products corresponding to reaction product of di-*tert*-butyl phosphonite with biphosphorous trichloride, reaction products with biphenyl and 2,4-bis(1,1-dimethylethyl)phenol:

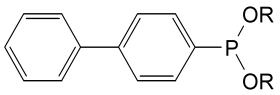


component I



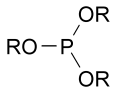
2,4-bis(1,1-dimethylethyl)phenyl biphenyl-4,4′-diyldiphosphonite

component II



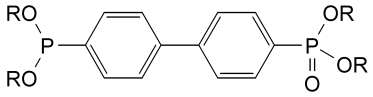
2,4-bis(1,1-dimethylethyl)phenyl biphenyl-3,4′-diyldiphosphonite

component III



2,4-bis(1,1-dimethylethyl)phenyl biphenyl-3,3′-diyldiphosphonite

component IV



2,4-bis(1,1-dimethylethyl)phenyl biphenyl-4-ylphosphonite

component V

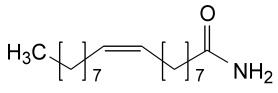
2,4-bis(1,1-dimethylethyl)phenyl phosphite

component VI

2,4-bis(1,1-dimethylethyl)phenyl 4′-[bis[2,4-bis(1,1-dimethylethyl)phenoxy]phosphanyl]biphenyl-4-ylphosphonate

component VII

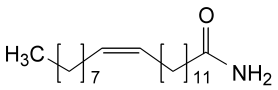
R-OH: 2,4-bis(1,1-dimethylethyl)phenol



add19. $C_{18}H_{36}O_2$. [57-11-4]. PM RN 24550.

octadecanoic acid

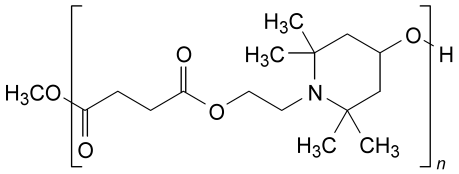
synonyms: — **stearic acid,**
— octadecanoic acid.



add20. $C_{18}H_{35}NO$. [301-02-0]. PM RN 68960.

(*Z*)-octadec-9-enamide

synonyms: — **oleamide,**
— 9-octadecenamide, (*Z*)-,
— 9-*cis*-oleamide.



add21. $C_{22}H_{43}NO$. [112-84-5]. PM RN 52720.

(*Z*)-docos-13-enamide

synonyms: — **erucamide,**
— 13-docosenamide, (*Z*)-,
— 13-*cis*-docosenamide.

add22. [65447-77-0]. PM RN 60800.

copolymer of dimethyl butanedioate and 1-(2-hydroxyethyl)-2,2,6,6-tetramethylpiperidin-4-ol

synonyms: — **copolymer of dimethyl succinate and (4-hydroxy-2,2,6,6-tetramethylpiperidin-1-yl)ethanol.**

corrected 6.0

3.1.14. MATERIALS BASED ON PLASTICISED POLY(VINYL CHLORIDE) FOR CONTAINERS FOR AQUEOUS SOLUTIONS FOR INTRAVENOUS INFUSION

DEFINITION

Materials based on plasticised poly(vinyl chloride) contain not less than 55 per cent of poly(vinyl chloride) and contain various additives, in addition to the high-molecular-mass polymer obtained by polymerisation of vinyl chloride.

Materials based on plasticised poly(vinyl chloride) for containers for aqueous solutions for intravenous infusion are defined by the nature and the proportions of the substances used in their manufacture.

PRODUCTION

Materials based on plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test:

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (*2.2.28*), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject the remaining 25 ml of vinyl chloride slowly into the vial shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into five of the vials. The six solutions thus obtained contain, respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamide R* and 5 per cent *m/m* of *macrogol 400 R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 45 °C, that of the injection port at 100 °C and that of the detector at 150 °C.

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

Additives

A certain number of additives is added to the polymers to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the following list which specifies for each product the maximum allowable content:

- not more than 40 per cent of di(2-ethylhexyl)phthalate (plastic additive 01),
- not more than 1 per cent of zinc octanoate (zinc 2-ethylhexanoate) (plastic additive 02),
- not more than 1 per cent of calcium stearate or zinc stearate or 1 per cent of a mixture of the two,
- not more than 1 per cent of *N,N'*-diacylethylenediamines (plastic additive 03),
- not more than 10 per cent of one of the following epoxidised oils or 10 per cent of a mixture of the two:
  - epoxidised soya oil (plastic additive 04) of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6,
  - epoxidised linseed oil (plastic additive 05) of which the oxiran oxygen content is not greater than 10 per cent and the iodine value is not greater than 7.

When colouring materials are added, ultramarine blue is used. Other inorganic pigments may be added, provided the safety of the material is demonstrated to the satisfaction of the competent authority. Very low amounts of antioxidants added to the vinyl chloride monomer used may be detected in the polymer.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Colourless or pale yellow material in the form of powder, beads, granules or, after transformation, translucent sheets of varying thicknesses, with a slight odour. On combustion it gives off dense, black smoke.

IDENTIFICATION

If necessary, before use, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

To 2.0 g of the material to be examined add 200 ml of *peroxide-free ether R* and heat under a reflux condenser for 8 h. Separate the residue B and the solution A by filtration.

Evaporate solution A to dryness under reduced pressure in a water-bath at 30 °C. Dissolve the residue in 10 ml of *toluene R* (solution A1). Dissolve the residue B in 60 ml of *ethylene chloride R*, heating on a water-bath under a reflux condenser. Filter. Add the solution dropwise and with vigorous shaking to 600 ml of *heptane R* heated almost to boiling. Separate by filtration the coagulum B1 and the organic solution. Allow the latter to cool; separate the precipitate B2 that forms and filter through a tared sintered-glass filter (40) (*2.1.2*).

A. Dissolve the coagulum B1 in 30 ml of *tetrahydrofuran R* and add, in small volumes with shaking, 40 ml of *ethanol R*. Separate the precipitate B3 by filtration and dry in vacuo at a temperature not exceeding 50 °C over *diphosphorus pentoxide R*. Dissolve a few milligrams of precipitate B3 in l ml of *tetrahydrofuran R*, place a few drops of the solution obtained on a sodium chloride plate and evaporate to dryness in an oven at 100 °C to 105 °C. Examine by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *poly(vinyl chloride) CRS*.

B. Examine the residue C obtained in the test for plastic additives 01, 04 and 05 by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *plastic additive 01 CRS*.

TESTS

If necessary, before use, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 5.0 g in a combustion flask. Add 30 ml of *sulphuric acid R* and heat until a black, syrupy mass is obtained. Cool and add carefully 10 ml of *strong hydrogen peroxide solution R*. Heat gently. Allow to cool and add 1 ml of *strong hydrogen peroxide solution R*; repeat by alternating evaporation and addition of hydrogen peroxide solution until a colourless liquid is obtained. Reduce the volume to about 10 ml. Cool and dilute to 50.0 ml with *water R*.

Solution S2. Place 25 g in a borosilicate-glass flask. Add 500 ml of *water for injections R* and cover the neck of the flask with aluminium foil or a borosilicate-glass beaker. Heat in an autoclave at 121 ± 2 °C for 20 min. Allow to cool and decant the solution.

Appearance of solution S2. Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 100 ml of solution S2, add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S2 add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of *0.01 M hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*). Evaporate 100.0 ml of solution S2 to dryness. Dissolve the residue in 5.0 ml of *hexane R*. From 250 nm to 310 nm the absorbance is not greater than 0.25.

Reducing substances. *Carry out the test within 4 h of preparation of solution S2.* To 20.0 ml of solution S2 add 1 ml of *dilute sulphuric acid R* and 20.0 ml of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration using 20 ml of *water for injections R*. The difference between the titration volumes is not more than 2.0 ml.

Primary aromatic amines. To 2.5 ml of solution A1 obtained during the identification, add 6 ml of *water R* and 4 ml of *0.1 M hydrochloric acid*. Shake vigorously and discard the upper layer. To the aqueous layer add 0.4 ml of a freshly prepared 10 g/l solution of *sodium nitrite R*. Mix and allow to stand for 1 min. Add 0.8 ml of a 25 g/l solution of *ammonium sulphamate R*, allow to stand for 1 min and add 2 ml of a 5 g/l solution of *naphthylethylenediamine dihydrochloride R*. After 30 min, any colour in the solution is not more intense than that in a standard prepared at the same time in the same manner using a mixture of 1 ml of a 0.01 g/l solution of *naphthylamine R* in *0.1 M hydrochloric acid*, 5 ml of *water R* and 4 ml of *0.1 M hydrochloric acid* instead of the aqueous layer (20 ppm).

Plastic additives 01, 04 and 05. Examine by thin-layer chromatography (*2.2.27*), using a *TLC silica gel* GF_{254} *plate R* (1 mm thick).

Reference solutions. Prepare 0.1 mg/ml solutions of *plastic additive 01 CRS*, *plastic additive 04 CRS* and *plastic additive 05 CRS*, respectively, in *toluene R*.

Apply to the plate as a band 30 mm by 3 mm, 0.5 ml of solution A1 obtained during the identification. Apply to the plate 5 µl of each reference solution. Develop over a path of 15 cm using *toluene R*. Dry the plate carefully. Examine in ultraviolet light at 254 nm and locate the zone corresponding to plastic additive 01 (R_F about 0.4). Remove the area of silica gel corresponding to this zone and shake with 40 ml of *ether R* for 1 min. Filter, rinse with two quantities, each of 10 ml of *ether R*, add the rinsings to the filtrate and evaporate to dryness. The residue C weighs not more than 40 mg.

Expose the plate to iodine vapour for 5 min. Examine the chromatogram and locate the band corresponding to plastic additives 04 and 05 (R_F = 0). Remove the area of silica gel corresponding to this zone. Similarly remove a corresponding area of silica gel as a blank reference. Separately shake both samples for 15 min with 40 ml of *methanol R*. Filter, rinse with two quantities, each of 10 ml of *methanol R*, add the rinsings to the filtrate and evaporate to dryness. The difference between the masses of both residues is not more than 10 mg.

Plastic additive 03. Wash precipitate B2 obtained during the identification and contained in the tared sintered-glass filter (40) (*2.1.2*) with *ethanol R*. Dry to constant mass over *diphosphorus pentoxide R* and weigh the filter. The precipitate weighs not more than 20 mg.

Examine the residue by infrared absorption spectrophotometry (*2.2.24*) comparing with the spectrum obtained with *plastic additive 03 CRS*.

Barium. Not more than 5.0 ppm of Ba, examined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Ignite 1.0 g of the substance to be examined in a silica crucible. Take up the residue with 10 ml of *hydrochloric acid R* and evaporate to dryness on a water-bath. Take up the residue with 20 ml of *0.1 M hydrochloric acid*.

Reference solution. A solution containing 0.25 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Cadmium. Not more than 0.6 ppm of Cd, determined by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Evaporate 10 ml of solution S1 to dryness. Take up the residue using 5 ml of a 1 per cent *V/V* solution of *hydrochloric acid R*, filter and dilute the filtrate to 10.0 ml with the same acid.

Reference solutions. Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluted with a l per cent *V/V* solution of *hydrochloric acid R*.

Measure the absorbance at 228.8 nm using a cadmium hollow-cathode lamp as the source of radiation and an air-acetylene flame.

Verify the absence of cadmium in the hydrochloric acid used.

Calcium. Not more than 0.07 per cent of Ca, examined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Use the test solution prepared for the determination of barium.

Reference solution. A solution containing 50.0 ppm of calcium prepared by dilution of *calcium standard solution (400 ppm Ca) R* with *0.1 M hydrochloric acid*.

Carry out the determination using the emission of calcium at 315.89 nm, the spectral background being taken at 315.60 nm.

Verify the absence of calcium in the hydrochloric acid used.

Tin. Not more than 20.0 ppm of Sn, examined by atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Dilute solution S1 ten times with *water R* immediately before use.

Reference solution. Introduce 2 ml of *tin standard solution (5 ppm (Sn) R)* into a 50 ml flask containing 5 ml of a 20 per cent *V/V* solution of *sulphuric acid R* and dilute to 50 ml with *water R* immediately before use.

Carry out the determination using the emission of tin at 189.99 nm, the spectral background being taken at 190.10 nm.

Verify the absence of tin in the hydrochloric acid used.

Zinc. Not more than 0.20 per cent of Zn, determined by atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Dilute solution S1 100 times with *0.1 M hydrochloric acid*.

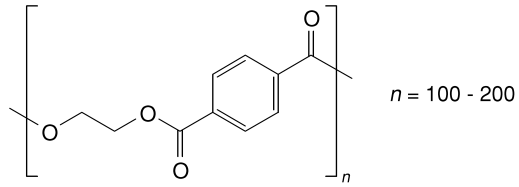
Reference solutions. Prepare the reference solutions using *zinc standard solution (100 ppm Zn) R*, diluted with *0.1 M hydrochloric acid*.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as the source of radiation and an air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Heavy metals (*2.4.8*). To 10 ml of solution S1 add 0.5 ml of *phenolphthalein solution R* and then *strong sodium hydroxide solution R* until a pale pink colour is obtained. Dilute to 25 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (50 ppm). Prepare the standard using *lead standard solution (2 ppm Pb) R*.

Water extractable substances. Evaporate 50 ml of solution S2 to dryness on a water-bath and dry at 100 °C to 105 °C until constant mass. Carry out a blank titration with 50.0 ml of *water for injections R*. The residue weighs not more than 7.5 mg (0.3 per cent) taking into account the blank test.



ASSAY

Carry out the oxygen-flask method (*2.5.10*) using 50.0 mg. Absorb the combustion products in 20 ml of *1 M sodium hydroxide*. To the solution obtained add 2.5 ml of *nitric acid R*, 10.0 ml of *0.1 M silver nitrate*, 5 ml of *ferric ammonium sulphate solution R2* and 1 ml of *dibutyl phthalate R*. Titrate with *0.05 M ammonium thiocyanate* until a reddish-yellow colour is obtained. Carry out a blank test.

1 ml of *0.1 M silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

corrected 6.0

3.1.15. POLYETHYLENE TEREPHTHALATE FOR CONTAINERS FOR PREPARATIONS NOT FOR PARENTERAL USE

DEFINITION

Polyethylene terephthalate is obtained from the polymerisation of terephthalic acid or dimethyl terephthalate with ethylene glycol. Isophthalic acid, dimethyl isophthalate, 1,4-bis(hydroxymethyl)cyclohexane (cyclohexane-1,4-dimethanol) or diethylene glycol may be used in the polymerisation. It may contain not more than 0.5 per cent of silica or silicates and colouring matter approved by the competent authority.

PRODUCTION

The manufacturing process is validated to demonstrate that the residual acetaldehyde content is not greater than 10 ppm in the granules.

CHARACTERS

Appearance: clear or opaque granules.

Solubility: practically insoluble in water, in alcohol and in methylene chloride. It is hydrolysed by strong bases.

IDENTIFICATION

A. Place 0.10 g of the material to be examined into a borosilicate glass flask with a ground-glass neck. Add 25 ml of a 200 g/l solution of *potassium hydroxide R* in a 50 per cent *V/V* solution of *ethanol R*. Reflux for 30 min. Allow to cool and dilute to 100 ml with *water R*. Filter if necessary. Dilute 1.0 ml of the filtrate to 100 ml with *water R*. Examined between 210 nm and 330 nm (*2.2.25*), the solution shows an absorption maximum at 240 nm.

B. Dissolve 0.05 g of the material to be examined in 2 ml of *1,1,1,3,3,3-hexafluoropropan-2-ol R*. Apply to a glass plate on a water-bath in a fume-cupboard several drops of the solution to produce a film of about 15 mm by 15 mm. Allow the solvent to evaporate and remove the film using a stream of water and a scraper. Dry in an oven at 100-105 °C for 1-2 h. Examine the film by infrared absorption spectrophotometry (*2.2.24*). The spectrum of the material to be examined shows maxima in particular at 1725 cm^{-1}, 1410 cm^{-1}, 1265 cm^{-1}, 1120 cm^{-1}, 1100 cm^{-1}, 1020 cm^{-1}, 875 cm^{-1}, 725 cm^{-1}. The spectrum obtained, in addition, is identical to that of the material selected for the type sample.

TESTS

If necessary, cut out samples for testing to a maximum size of 1 cm per side.

Solution S1. Place 10.0 g of the material to be examined in a borosilicate glass flask with a ground-glass neck. Add 200 ml of *water R* and heat at 50 °C for 5 h. Allow to cool and decant the solution. *Use solution S1 within 4 h of its preparation.*

Solution S2. Place 10 g of the material to be examined in a borosilicate glass flask with a ground-glass neck. Add 100 ml of *alcohol R* and heat at 50 °C for 5 h. Allow to cool and decant the solution. *Use solution S2 within 4 h of its preparation.*

Solution S3. Place 20 g of the material to be examined in a borosilicate glass flask with a ground-glass neck. Add 50 ml of *0.1 M hydrochloric acid* and heat at 50 °C for 5 h. Allow to cool and decant the solution. *Use solution S3 within 4 h of its preparation.*

Solution S4. Place 20 g of the material to be examined into a borosilicate glass flask with a ground-glass neck. Add 50 ml of *0.01 M sodium hydroxide* and heat at 50 °C for 5 h. Allow to cool and decant. *Use solution S4 within 4 h of its preparation.*

Appearance of solution S1. Solution S1 is clear (*2.2.1*).

Appearance of solution S2. Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 50 ml of solution S1 add 0.15 ml of *BRP indicator solution R*. The solution turns yellow. Not more than 0.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To another 50 ml of solution S1 add 0.2 ml of *methyl orange solution R*. The solution turns yellow. Not more than 0.5 ml of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator to orange.

Absorbance of solution S1 (*2.2.25*): maximum 0.20 between 220 nm and 340 nm. In addition, for coloured polyethylene terephthalate: maximum 0.05 between 400 nm to 800 nm.

Absorbance of solution S2 (*2.2.25*): maximum 0.05 between 400 nm and 800 nm.

Reducing substances. Add 2 ml of *0.5 M sulphuric acid* and 20.0 ml of *0.002 M potassium permanganate* to 20.0 ml of solution S1. Boil for 3 min. Cool immediately to ambient

temperature. Add 1 g of *potassium iodide R*, 0.25 ml of *starch solution R* as indicator and titrate with *0.01 M sodium thiosulphate*. Perform a blank titration using 20.0 ml of *water R*. The difference in volume used in the 2 titrations is not greater than 0.5 ml.

Substances soluble in dioxan: maximum 3 per cent.

Place 2 g of the material to be examined in a borosilicate glass flask with a ground-glass neck. Add 20 ml of *dioxan R* and heat under reflux for 2 h. Evaporate 10 ml of the solution to dryness on a water-bath and then dry the residue at 100-105 °C. The residue weighs a maximum of 30 mg.

Extractable aluminium: maximum 1.0 ppm.

Atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S3.

Reference solutions. Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluted with *0.1 M hydrochloric acid*.

Wavelength: 396.15 nm, the spectral background being taken at 396.25 nm.

Verify the absence of aluminium in the *0.1 M hydrochloric acid* used.

Extractable antimony: maximum 1.0 ppm.

Atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S4.

Reference solutions. Prepare the reference solutions using *antimony standard solution (100 ppm Sb) R*, diluted with *0.01 M sodium hydroxide*.

Wavelength: 231.15 nm or 217.58 nm, the spectral background being taken at 231.05 nm.

Extractable barium: maximum 1.0 ppm.

Atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S3.

Reference solutions. Prepare the reference solutions using *barium standard solution (50 ppm Ba) R*, diluted with *0.1 M hydrochloric acid*.

Wavelength: 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the *0.1 M hydrochloric acid* used.

Extractable cobalt: maximum 1.0 ppm.

Atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S3.

Reference solutions. Prepare the reference solutions using *cobalt standard solution (100 ppm Co) R*, diluted with *0.1 M hydrochloric acid*.

Wavelength: 228.62 nm, the spectral background being taken at 228.50 nm.

Verify the absence of cobalt in the *0.1 M hydrochloric acid* used.

Extractable germanium: maximum 1.0 ppm.

Atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S4.

Reference solutions. Prepare the reference solutions using *germanium standard solution (100 ppm Ge) R*, diluted with *0.01 M sodium hydroxide*.

Wavelength: 206.87 nm or 265.12 nm, the spectral background being taken at 206.75 nm.

Extractable manganese: maximum 1.0 ppm.

Atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S3.

Reference solutions. Prepare the reference solutions using *manganese standard solution (100 ppm Mn) R*, diluted with *0.1 M hydrochloric acid*.

Wavelength: 257.61 nm, the spectral background being taken at 257.50 nm.

Verify the absence of manganese in the *0.1 M hydrochloric acid* used.

Extractable titanium: maximum 1.0 ppm.

Atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S3.

Reference solutions. Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluted with *0.1 M hydrochloric acid*.

Wavelength: 323.45 nm or 334.94 nm, the spectral background being taken at 323.35 nm.

Verify the absence of titanium in the 0.1M hydrochloric acid used.

Extractable zinc: maximum 1.0 ppm.

Atomic emission spectrometry in an argon plasma (*2.2.22, Method I*).

Test solution. Solution S3.

Reference solutions. Prepare the reference solutions using *zinc standard solution (100 ppm Zn) R*, diluted with *0.1 M hydrochloric acid*.

Wavelength: 213.86 nm, the spectral background being taken at 213.75 nm.

Verify the absence of zinc in the *0.1 M hydrochloric acid* used.

Sulphated ash (*2.4.14*): maximum 0.5 per cent determined on 1.0 g.

3.2. CONTAINERS

A container for pharmaceutical use is an article that contains or is intended to contain a product and is, or may be, in direct contact with it. The closure is a part of the container.

The container (see General Notices section 1.3) is so designed that the contents may be removed in a manner appropriate to the intended use of the preparation. It provides a varying degree of protection depending on the nature of the product and the hazards of the environment, and minimises the loss of constituents. The container does not interact physically or chemically with the contents in a way that alters their quality beyond the limits tolerated by official requirements.

Single-dose container. A single-dose container holds a quantity of the preparation intended for total or partial use on 1 occasion only.

Multidose container. A multidose container holds a quantity of the preparation suitable for 2 or more doses.

Well-closed container. A well-closed container protects the contents from contamination with extraneous solids and liquids and from loss of contents under ordinary conditions of handling, storage and transport.

Airtight container. An airtight container is impermeable to solids, liquids and gases under ordinary conditions of handling, storage and transport. If the container is intended to be opened on more than 1 occasion, it must be so designed that it remains airtight after re-closure.

Sealed container. A sealed container is a container closed by fusion of the material of the container.

Tamper-proof container. A tamper-proof container is a closed container fitted with a device that reveals irreversibly whether the container has been opened.

Child-proof container. A container that is fitted with a closure that prevents opening by children.

01/2008:30201

3.2.1. GLASS CONTAINERS FOR PHARMACEUTICAL USE

Glass containers for pharmaceutical use are glass articles intended to come into direct contact with pharmaceutical preparations.

Colourless glass is highly transparent in the visible spectrum.

Coloured glass is obtained by the addition of small amounts of metal oxides, chosen according to the desired spectral absorbance.

Neutral glass is a borosilicate glass containing significant amounts of boric oxide, aluminium oxide alkali and/or alkaline earth oxides. Due to its composition neutral glass has a high hydrolytic resistance and a high thermal shock resistance.

Soda-lime-silica glass is a silica glass containing alkali metal oxides, mainly sodium oxide and alkaline earth oxides, mainly calcium oxide. Due to its composition soda-lime-silica glass has only a moderate hydrolytic resistance.

The hydrolytic stability of glass containers for pharmaceutical use is expressed by the resistance to the release of soluble mineral substances into water under the prescribed conditions of contact between the inner surface of the container or glass grains and water. The hydrolytic resistance is evaluated by titrating released alkali. According to their hydrolytic resistance, glass containers are classified as follows:

- Type I glass containers: neutral glass, with a high hydrolytic resistance due to the chemical composition of the glass itself,
- Type II glass containers: usually of soda-lime-silica glass with a high hydrolytic resistance resulting from suitable treatment of the surface,
- Type III glass containers: usually of soda-lime-silica glass with only moderate hydrolytic resistance.

The following italicised statements constitute general recommendations concerning the type of glass container that may be used for different types of pharmaceutical preparations. The manufacturer of a pharmaceutical product is responsible for ensuring the suitability of the chosen container.

Type I glass containers are suitable for most preparations whether or not for parenteral use.

Type II glass containers are suitable for most acidic and neutral, aqueous preparations whether or not for parenteral use.

Type III glass containers are in general suitable for non-aqueous preparations for parenteral use, for powders for parenteral use (except for freeze-dried preparations) and for preparations not for parenteral use.

Glass containers with a hydrolytic resistance higher than that recommended above for a particular type of preparation may generally also be used.

The container chosen for a given preparation shall be such that the glass material does not release substances in quantities sufficient to affect the stability of the preparation or to present a risk of toxicity. In justified cases, it may be necessary to have detailed information on the glass composition, so that the potential hazards can be assessed.

Preparations for parenteral use are normally presented in colourless glass, but coloured glass may be used for substances known to be light-sensitive. Colourless or coloured glass is used for the other pharmaceutical preparations. It is recommended that all glass containers for liquid preparations and for powders for parenteral use permit the visual inspection of the contents.

The inner surface of glass containers may be specially treated to improve hydrolytic resistance, to confer water-repellancy, etc. The outer surface may also be treated, for example to reduce friction and to improve resistance to abrasion. The outer treatment is such that it does not contaminate the inner surface of the container.

Except for type I glass containers, glass containers for pharmaceutical preparations are not to be re-used. Containers for human blood and blood components must not be re-used.

Glass containers for pharmaceutical use comply with the relevant test or tests for hydrolytic resistance. When glass containers have non-glass components, the tests apply only to the glass part of the container.

To define the quality of glass containers according to the intended use, one or more of the following tests are necessary.

Tests for hydrolytic resistance are carried out to define the type of glass (I, II or III) and to control its hydrolytic resistance.

In addition, containers for aqueous parenteral preparations are tested for arsenic release and coloured glass containers are tested for spectral transmission.

HYDROLYTIC RESISTANCE

Table 3.2.1.-1. – *Types of glass*

Type of container	Test to be performed
Type I and Type II glass containers (to distinguish from Type III glass containers)	Test A (surface test)
Type I glass containers (to distinguish from Type II and Type III glass containers)	Test B (glass grains test) or test C (etching test)
Type I and Type II glass containers where it is necessary to determine whether the high hydrolytic resistance is due to the chemical composition or to the surface treatment	Tests A and B, or tests A and C

The test is carried out by titration of the extract solutions obtained under the conditions described for tests A, B and C.

EQUIPMENT

- an autoclave capable of maintaining a temperature of 121 °C ± 1 °C, equipped with a thermometer or a calibrated thermocouple recorder, a pressure gauge, a vent cock and a tray, of sufficient capacity to accommodate above the water level the number of containers needed to carry out the test; *clean the autoclave vessel and all ancillary equipment thoroughly before use with water R;*
- burettes with a suitable capacity;
- one-mark volumetric flasks, with a capacity of 1000 ml;
- pipettes and beakers;
- conical flasks with a capacity of 100 ml and 250 ml;
- a water-bath;
- a metal foil (e.g. aluminium, stainless steel).

Flasks and beakers shall have been already used for the test or have been filled with *water R* and kept in an autoclave at 121 °C at least for 1 h before being used.

DETERMINATION OF THE FILLING VOLUME

The filling volume is the volume of water to be filled in the container for the purpose of the test. For vials and bottles the filling volume is 90 per cent of the brimful capacity. For ampoules it is the volume up to the height of the shoulder.

Vials and bottles. Select, at random, 6 containers from the sample lot, or 3 if their capacity exceeds 100 ml, and remove any dirt or debris. Weigh the empty containers with an accuracy of 0.1 g. Place the containers on a horizontal surface and fill them with *distilled water R* until about the rim edge, avoiding overflow and introduction of air bubbles. Adjust the liquid levels to the brimful line. Weigh the filled containers to obtain the mass of the water expressed to 2 decimal places for containers having a nominal volume less or equal to 30 ml, and expressed to 1 decimal place for containers having a nominal volume greater than 30 ml. Calculate the mean value of the brimful capacity in millilitres and multiply it by 0.9. This volume, expressed to 1 decimal place, is the filling volume for the particular container lot.

Ampoules. Place at least 6 dry ampoules on a flat, horizontal surface and fill them with *distilled water R* from a burette, until the water reaches point A, where the body of the ampoule declines to the shoulder (see Figure 3.2.1.-1). Read the capacities (expressed to 2 decimal places) and calculate the mean value. This volume, expressed to 1 decimal place, is the filling volume for the particular ampoule lot. The filling volume may also be determined by weighing.

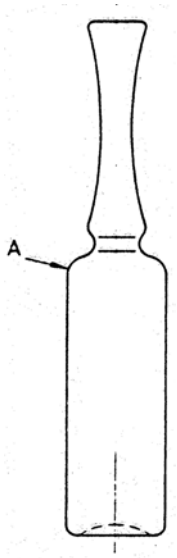

Figure 3.2.1.-1. – *Filling volume of ampoules (up to point A)*

TEST A. HYDROLYTIC RESISTANCE OF THE INNER SURFACES OF GLASS CONTAINERS (SURFACE TEST)

The determination is carried out on unused containers. The volumes of the test liquid necessary for the final determination are indicated in Table 3.2.1.-2.

Table 3.2.1.-2. – *Volume of test liquid and number of titrations*

Filling volume (ml)	Volume of test liquid for one titration (ml)	Number of titrations
Up to 3	25.0	1
Above 3 and up to 30	50.0	2
Above 30 and up to 100	100.0	2
Above 100	100.0	3

Cleaning. Remove any debris or dust. Shortly before the test, rinse each container carefully at least twice with *water R* and allow to stand. Immediately before testing empty the containers, rinse once with *water R* then with *water R1* and allow to drain. Complete the cleaning procedure from the first rinsing in not less than 20 min and not more than 25 min.

Heat closed ampoules on a water-bath or in an air-oven at about 50 °C for approximately 2 min before opening; do not rinse before testing.

Filling and heating. The containers are filled with *water R1* up to the filling volume. Containers in the form of cartridges or prefilled syringes are closed in a suitable manner with material that does not interfere with the test. Each container including ampoules shall be loosely capped with an inert material such as a dish of neutral glass or aluminium foil previously rinsed with *water R*. Place the containers on the tray of the autoclave. Place the tray in the autoclave containing a quantity of *water R* such that the tray remains clear of the water. Close the autoclave and carry out the following operations:

- heat the autoclave to 100 °C and allow the steam to issue from the vent cock for 10 min;
- close the ventcock and raise the temperature from 100 °C to 121 °C at a rate of 1 °C per min;
- maintain the temperature at 121 ± 1 °C for 60 ± 1 min;

– lower the temperature from 121 °C to 100 °C at a rate of 0.5 °C per min, venting to prevent vacuum;
– do not open the autoclave before it has cooled down to 95 °C;
– remove the containers from the autoclave using normal precautions, place them in a water-bath at 80 °C, and run cold tap water, taking care that the water does not contact the loose foil caps to avoid contamination of the extraction solution;
– cooling time does not exceed 30 min.

The extraction solutions are analysed by titration according to the method described below.

Method. Carry out the titration within 1 h of removal of the containers from the autoclave. Combine the liquids obtained from the containers and mix. Introduce the prescribed volume (Table 3.2.1.-2) into a conical flask. Place the same volume of *water R1* into a second similar flask as a blank. Add to each flask 0.05 ml of *methyl red solution R* for each 25 ml of liquid. Titrate the blank with *0.01 M hydrochloric acid*. Titrate the test liquid with the same acid until the colour of the resulting solution is the same as that obtained for the blank. Subtract the value found for the blank titration from that found for the test liquid and express the results in millilitres of *0.01 M hydrochloric acid* per 100 ml. Express titration values of less than 1.0 ml to 2 decimal places and titration values of more than or equal to 1.0 ml to 1 decimal place.

Limits. The results, or the average of the results if more than one titration is performed, is not greater than the values stated in Table 3.2.1.-3.

Table 3.2.1.-3. – *Limit values in the test for surface hydrolytic resistance*

	Maximum volume of 0.01 M HCl per 100 ml of test liquid (ml)	
	Glass containers	
Filling volume (ml)	**Types I and II**	**Type III**
Up to 1	2.0	20.0
Above 1 and up to 2	1.8	17.6
Above 2 and up to 5	1.3	13.2
Above 5 and up to 10	1.0	10.2
Above 10 and up to 20	0.80	8.1
Above 20 and up to 50	0.60	6.1
Above 50 and up to 100	0.50	4.8
Above 100 and up to 200	0.40	3.8
Above 200 and up to 500	0.30	2.9
Above 500	0.20	2.2

TEST B. HYDROLYTIC RESISTANCE OF GLASS GRAINS (GLASS GRAINS TEST)

Check that the articles as received have been annealed to a commercially acceptable quality.

The test may be performed on the canes used for the manufacture of tubing glass containers or on the containers.

Equipment

– a mortar, pestle (see Figure 3.2.1.-2) and hammer in tempered, magnetic steel,
– a set of 3 square-mesh sieves of stainless steel, mounted on frames of the same material and consisting of the following:
  (a) sieve no. 710,
  (b) sieve no. 425,
  (c) sieve no. 300;
– a permanent magnet;
– a metal foil (e.g. aluminium, stainless steel);
– a hot-air oven, capable of maintaining a temperature of 140 ± 5 °C;
– a balance, capable of weighing up to 500 g with an accuracy of 0.005 g;
– a desiccator;
– an ultrasonic bath.

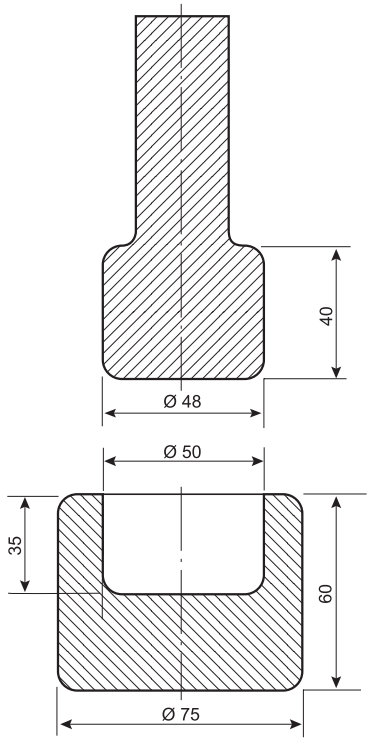

Figure 3.2.1.-2. – *Apparatus for glass grains method (dimensions in millimetres)*

Method. Rinse the containers to be tested with *water R* and dry in the oven. Wrap at least 3 of the glass articles in clean paper and crush to produce 2 samples of about 100 g each in pieces not more than 30 mm across. Place 30-40 g of the pieces between 10-30 mm across taken from 1 of the samples in the mortar, insert the pestle and strike it heavily once only with the hammer. Transfer the contents of the mortar, to the coarsest sieve (a) of the set. Repeat the operation until all fragments have been transferred to the sieve. Shake the set of sieves a short time by hand and remove the glass which remains on sieves (a) and (b). Submit these portions to further fracture, repeating the operation until about 10 g of glass remains on sieve (a). Reject this portion and the portion which passes through sieve (c). Reassemble the set of sieves and shake for 5 min. Transfer to a weighing bottle those glass grains which passed through sieve (b) and are retained on sieve (c). Repeat the crushing and sieving procedure with the other glass sample and thus 2 samples of grains, each of which shall be in excess of 10 g, are obtained. Spread each sample on a piece of clean glazed paper and remove any iron particles by passing the magnet over them. Transfer each sample into a beaker for cleaning. Add to the grains in each beaker 30 ml of *acetone R* and scour the grains by suitable means, such as a rubber or plastic-coated glass rod. After scouring the grains, allow to settle and decant as much acetone as possible. Add another 30 ml of *acetone R*, swirl, decant again and add a new portion of *acetone R*.

Fill the bath of the ultrasonic vessel with water at room temperature, then place the beaker in the rack and immerse

it until the level of the acetone is at the level of the water; apply the ultrasound for 1 min. Swirl the beaker, allow to settle and decant the acetone as completely as possible and then repeat the ultrasonic cleaning operation. If a fine turbidity persists, repeat the ultrasonic cleaning and acetone washing until the solution remains clear. Swirl and decant the acetone then dry the grains, first by putting the beaker on a warm plate to remove excess acetone and then by heating at 140 °C for 20 min in the drying oven. Transfer the dried grains from each beaker into separate weighing bottles, insert the stoppers and cool in the desiccator. Weigh 10.00 g of the cleaned and dried grains into 2 separate conical flasks. Add 50 ml of *water R1* into each by means of a pipette (test solutions). Pipette 50 ml of *water R1* into a third conical flask which will serve as a blank. Distribute the grains evenly over the flat bases of the flasks by gentle shaking. Close the flasks with neutral glass dishes or aluminium foil rinsed with *water R* or with inverted beakers so that the inner surface of the beakers fit snugly down onto the top rims of the flasks. Place all 3 flasks in the rack in the autoclave containing the water at ambient temperature, and ensure that they are held above the level of the water in the vessel. Carry out the autoclaving procedure in a similar manner to that described under test A, but maintain the temperature of 121 ± 1 °C only for 30 ± 1 min. Do not open the autoclave until it has cooled to 95 °C. Remove the hot samples from the autoclave and cool the flasks in running tap water as soon as possible, avoiding thermal shock. To each of the 3 flasks add 0.05 ml of *methyl red solution R*. Titrate the blank solution immediately with *0.02 M hydrochloric acid* then titrate the test solutions until the colour matches that obtained with the blank solution. Substract the titration volume for the blank solution from that for the test solutions.

NOTE: where necessary to obtain a sharp end-point, the clear solution is to be decanted into a separate 250 ml flask. Rinse the grains with 3 quantities, each of 15 ml, of water R1 by swirling and add the washings to the main solution. Add 0.05 ml of the methyl red solution R. Titrate and calculate as described below. In this case also add 45 ml of water R1 and 0.05 ml of methyl red solution R to the blank solution.

Calculate the mean value of the results in millilitres of *0.02 M hydrochloric acid* per gram of the sample and if required its equivalent in alkali extracted, calculated as micrograms of sodium oxide per gram of glass grains.

1 ml of *0.02 M hydrochloric acid* is equivalent to 620 µg of sodium oxide.

Repeat the test if the highest and lowest observed values differ by more than 20 per cent.

Limits. Type I glass containers require not more than 1.0 ml of *0.02 M hydrochloric acid* (equivalent to 62 µg of Na_2O per gram of glass), Type II and Type III glass containers require not more than 8.5 ml of *0.02 M hydrochloric acid* (equivalent to 527 µg of Na_2O per gram of glass).

TEST C. TO DETERMINE WHETHER THE CONTAINERS HAVE BEEN SURFACE-TREATED (ETCHING TEST)

When it is necessary to determine if a container has been surface-treated, and/or distinguish between Type I and Type II glass containers, test C is used in addition to test A. Alternatively, test A and B may be used. Test C may be carried out either on unused samples or on samples previously tested for test A.

Vials and bottles. The volumes of test liquid required are shown in Table 3.2.1.-2.

Rinse the containers twice with *water R* and fill to the brimful point with a mixture of 1 volume of *hydrofluoric acid R* and 9 volumes of *hydrochloric acid R* and allow to stand for 10 min. Empty the containers and rinse carefully 5 times with *water R*. Immediately before the test, rinse once again with *water R*. Submit the containers thus prepared to the same autoclaving and determination procedure as described in test A for surface hydrolytic resistance. If the results are considerably higher than those obtained from the original surfaces (by about a factor of 5 to 10), the samples have been surface-treated.

Ampoules

NOTE: ampoules made from glass tubing are not normally subjected to internal surface treatment because their high chemical resistance is dependent upon the chemical composition of the glass as a material.

Apply the test method as described above for vials and bottles. If the ampoules are not surface-treated, the new values are slightly lower than those obtained in previous tests.

Distinction between Type I and Type II glass containers

The results obtained in Test C are compared to those obtained in Test A. The interpretation of the result is shown in Table 3.2.1.-4.

Table 3.2.1.-4. – *Distinction between Types I and II glass containers*

Type I	Type II
The values are closely similar to those found in the test for surface hydrolytic resistance for Type I glass containers.	The values greatly exceed those found in the test for surface hydrolytic resistance and are similar but not larger than those for Type III glass containers.

ARSENIC

The test applies to glass containers for aqueous parenteral preparations.

Hydride generation atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Use the extract solution obtained from containers of Types I and II, after autoclaving at 121 °C for 1 h as described under test A for surface hydrolytic resistance. Transfer 10.0 ml to a 100 ml volumetric flask. Add 10 ml of *hydrochloric acid R* and 5 ml of a 200 g/l solution of *potassium iodide R*. Heat on a water-bath at 80 °C for 20 min, allow to cool and dilute to 100.0 ml with *water R*.

Reference solutions. Prepare the reference solutions using *arsenic standard solution (1 ppm As) R*. Add 10 ml of *hydrochloric acid R* and 5 ml of a 200 g/l solution of *potassium iodide R*. Heat on a water-bath at 80 °C for 20 min, allow to cool and dilute to 100.0 ml with *water R*. The concentration range of the reference solutions is typically 0.005 ppm to 0.015 ppm of As.

Acid reservoir. Hydrochloric acid R.

Reducing reservoir. Sodium tetrahydroborate reducing solution R.

Use a hydride generation device to introduce the test solution into the cuvette of an atomic absorption spectrometer. Establish and standardise instrumental operating conditions according to the manufacturer's instructions, optimise the uptake rate of the peristaltic pump tubings, then connect tubings to the acid reservoir, the reducing reservoir and the test solution.

Source: hollow-cathode lamp.

Wavelength: 193.7 nm.

Atomisation device: air-acetylene flame.

Limit: maximum 0.1 ppm of As.

SPECTRAL TRANSMISSION FOR COLOURED GLASS CONTAINERS

Equipment. A UV-VIS spectrophotometer, equipped with a photodiode detector or equipped with a photomultiplier tube coupled with an integrating sphere.

Preparation of the specimen. Break the glass container or cut it with a circular saw fitted with a wet abrasive wheel, such as a carborundum or a bonded-diamond wheel. Select sections representative of the wall thickness and trim them as suitable for mounting in a spectrophotometer. If the specimen is too small to cover the opening in the specimen holder, mask the uncovered portion with opaque paper or tape, provided that the length of the specimen is greater than that of the slit. Before placing in the holder, wash, dry and wipe the specimen with lens tissue. Mount the specimen with the aid of wax, or by other convenient means, taking care to avoid leaving fingerprints or other marks.

Method. Place the specimen in the spectrophotometer with its cylindrical axis parallel to the slit and in such a way that the light beam is perpendicular to the surface of the section and that the losses due to reflection are at a minimum. Measure the transmission of the specimen with reference to air in the spectral region of 290-450 nm, continuously or at intervals of 20 nm.

Limits. The observed spectral transmission for coloured glass containers for preparations that are not for parenteral use does not exceed 10 per cent at any wavelength in the range of 290 nm to 450 nm, irrespective of the type and the capacity of the glass container. The observed spectral transmission in coloured glass containers for parenteral preparations does not exceed the limits given in Table 3.2.1.-5.

Table 3.2.1.-5. – *Limits of spectral transmission for coloured glass containers for parenteral preparations*

	Maximum percentage of spectral transmission at any wavelength between 290 nm and 450 nm	
Filling volume (ml)	**Flame-sealed containers**	**Containers with closures**
Up to 1	50	25
Above 1 and up to 2	45	20

Above 20	25	10

Annex - test for surface hydrolytic resistance - determination by flame atomic absorption spectrometry (faas)

The surface hydrolytic resistance of glass of Types I and II may be determined by analysis of the leaching solution by flame atomic absorption spectrometry. A number of elements that, when present as oxides in glass, contribute to the alkalinity of the solution, are determined and used to express an alkali equivalent. The spectrometric method has the advantage of allowing the use of a much smaller sample of extract so that it can be applied to small individual containers. This enables an evaluation of the uniformity of the containers in a given batch where this is critical. The results of this measurement are not equivalent to those of titrimetry and the 2 methods cannot be considered interchangeable. A correlation between the 2 is dependent on the type of glass and the size and shape of the container.

The titrimetric method is the reference method of the Pharmacopoeia; the spectrometric method may be used in justified and authorised cases.

A method suitable for this type of analysis is shown below.

The determination is carried out on unused containers. The number of containers to be examined is indicated in Table 3.2.1.-6.

Table 3.2.1.-6. - *Number of containers to be examined for the spectrometric method*

Filling volume (ml)	Number of containers to be measured separately	Additional containers for preliminary measurements
Up to 2	20	2
Above 2 and up to 5	15	2
Above 5 and up to 30	10	2
Above 30 and up to 100	5	1
Above 100	3	1

Instructions on determination of the filling volume, cleaning of the containers, filling and heating are given above under Hydrolytic resistance and Test A. Hydrolytic resistance of the inner surfaces of glass containers.

SOLUTIONS

Spectrochemical buffer solution. Dissolve 80 g of *caesium chloride R* in about 300 ml of *water R1*, add 10 ml of *6 M hydrochloric acid R* and transfer to a 1000 ml volumetric flask. Dilute to volume with *water R1* and mix.

Stock solutions:

- sodium oxide, $c(Na_2O)$ = 1 mg/ml,
- potassium oxide, $c(K_2O)$ = 1 mg/ml,
- calcium oxide, $c(CaO)$ = 1 mg/ml.

Commercially available stock solutions may also be used.

Standard solutions. Prepare standard solutions by diluting the stock solutions with *water R1* to obtain concentrations suitable for establishing the reference solutions in appropriate manner, e.g. with concentrations of 20 µg/ml of sodium oxide, potassium oxide and calcium oxide, respectively. Commercially available standard solutions may also be used.

Reference solutions. Prepare the reference solutions for establishing the calibration graph (set of calibration solutions) by diluting suitable concentrated standard solutions with *water R1*, so that the normal working ranges of the specific elements are covered, taking into account the instrument used for the measurement. Typical concentration ranges of the reference solutions are:

- for determination by atomic emission spectrometry of sodium oxide and potassium oxide: up to 10 µg/ml,
- for determination by atomic absorption spectrometry of sodium oxide and potassium oxide: up to 3 µg/ml,
- for determination by atomic absorption spectrometry of calcium oxide: up to 7 µg/ml.

Use reference solutions containing 5 per cent *V/V* of the spectrochemical buffer solution.

METHOD

Carry out preliminary measurements of the potassium oxide and calcium oxide concentrations on one of the extraction solutions. If, for one container type, the concentration of potassium oxide is less than 0.2 µg/ml and if the concentration of calcium oxide is less than 0.1 µg/ml, the remaining extraction solutions of this container type need not be analysed for these ions. Aspirate the extraction solution from each sample directly into the flame of the atomic absorption or atomic emission instrument and

determine the approximate concentrations of sodium oxide (and potassium oxide and calcium oxide, if present) by reference to calibration graphs produced from the reference solutions of suitable concentration.

FINAL DETERMINATION

If dilution is unnecessary add to each container a volume of the spectrochemical buffer solution equivalent to 5 per cent of the filling volume, mix well and determine sodium oxide, calcium oxide and potassium oxide, if present, by reference to calibration graphs. For the determination of the calcium oxide concentration by flame atomic spectrometry, the nitrous oxide/acetylene flame shall be used.

If dilution is necessary, determine sodium oxide, calcium oxide and potassium oxide, if present, following the procedures as described above. The measuring solutions shall contain 5 per cent *V/V* of the spectrochemical buffer solution. Concentration values less than 1.0 µg/ml are expressed to 2 decimal places, values greater than or equal to 1.0 µg/ml to 1 decimal place. Correct the result for the buffer addition and for dilution, if any.

CALCULATION

Calculate the mean value of the concentration of individual oxides found in each of the samples tested, in micrograms of the oxide per millilitre of the extraction solution and calculate the sum of the individual oxides, expressed as micrograms of sodium oxide per millilitre of the extraction solution using the following mass conversion factors:

– 1 µg of potassium oxide corresponds to 0.658 µg of sodium oxide,
– 1 µg of calcium oxide corresponds to 1.105 µg of sodium oxide.

Limits. For each container tested, the result is not greater than the value given in Table 3.2.1.-7.

Table 3.2.1.-7. – *Limit values in the test for surface hydrolytic resistance by flame atomic absorption spectrometry*

	Maximum values for the concentration of oxides, expressed as sodium oxide (µg/ml)
Filling volume (ml)	**Glass containers**
	Types I and II
Up to 1	5.00
Above 1 and up to 2	4.50
Above 2 and up to 5	3.20
Above 5 and up to 10	2.50
Above 10 and up to 20	2.00
Above 20 and up to 50	1.50
Above 50 and up to 100	1.20
Above 100 and up to 200	1.00
Above 200 and up to 500	0.75
Above 500	0.50

3.2.2. PLASTIC CONTAINERS AND CLOSURES FOR PHARMACEUTICAL USE

A plastic container for pharmaceutical use is a plastic article which contains or is intended to contain a pharmaceutical product and is, or may be, in direct contact with it. The closure is a part of the container.

Plastic containers and closures for pharmaceutical use are made of materials in which may be included certain additives; these materials do not include in their composition any substance that can be extracted by the contents in such quantities as to alter the efficacy or the stability of the product or to present a risk of toxicity.

The most commonly used polymers are polyethylene (with and without additives), polypropylene, poly(vinyl chloride), poly(ethylene terephthalate) and poly(ethylene-vinyl acetate).

The nature and amount of the additives are determined by the type of the polymer, the process used to convert the polymer into the container and the intended purpose of the container. Additives may consist of antioxidants, stabilisers, plasticisers, lubricants, colouring matter and impact modifiers. Antistatic agents and mould-release agents may be used only for containers for preparations for oral use or for external use for which they are authorised. Acceptable additives are indicated in the type specification for each material described in the Pharmacopoeia. Other additives may be used provided they are approved in each case by the competent authority responsible for the licensing for sale of the preparation.

For selection of a suitable plastic container, it is necessary to know the full manufacturing formula of the plastic, including all materials added during formation of the container so that the potential hazards can be assessed. The plastic container chosen for any particular preparation should be such that:

– the ingredients of the preparation in contact with the plastic material are not significantly adsorbed on its surface and do not significantly migrate into or through the plastic,
– the plastic material does not release substances in quantities sufficient to affect the stability of the preparation or to present a risk of toxicity.

Using material or materials selected to satisfy these criteria, a number of identical type samples of the container are made by a well-defined procedure and submitted to practical testing in conditions that reproduce those of the intended use, including, where appropriate, sterilisation. In order to confirm the compatibility of the container and the contents and to ensure that there are no changes detrimental to the quality of the preparation, various tests are carried out such as verification of the absence of changes in physical characteristics, assessment of any loss or gain through permeation, detection of pH changes, assessment of changes caused by light, chemical tests and, where appropriate, biological tests.

The method of manufacture is such as to ensure reproducibility for subsequent bulk manufacture and the conditions of manufacture are chosen so as to preclude the possibility of contamination with other plastic materials or their ingredients. The manufacturer of the product must ensure that containers made in production are similar in every respect to the type samples.

For the results of the testing on type samples to remain valid, it is important that:

– there is no change in the composition of the material as defined for the type samples,
– there is no change in the manufacturing process as defined for the type samples, especially as regards the temperatures to which the plastic material is exposed during conversion or subsequent procedures such as sterilisation,
– scrap material is not used.

Recycling of excess material of well-defined nature and proportions may be permitted after appropriate validation.

Subject to satisfactory testing for compatibility of each different combination of container and contents, the materials described in the Pharmacopoeia are recognised as being suitable for the specific purposes indicated, as defined above.

01/2008:90003 corrected 6.0

3.2.2.1. PLASTIC CONTAINERS FOR AQUEOUS SOLUTIONS FOR INFUSION

DEFINITION

Plastic containers for aqueous solutions for infusion are manufactured from one or more polymers, if necessary with additives. The containers described in this section are not necessarily suitable for emulsions. The polymers most commonly used are polyethylene, polypropylene and poly(vinyl chloride). The specifications of this text are to be read in conjunction with section *3.2.2. Plastic containers and closures for pharmaceutical use*.

The containers may be bags or bottles. They have a site suitable for the attachment of an infusion set designed to ensure a secure connection. They may have a site that allows an injection to be made at the time of use. They usually have a part that allows them to be suspended and which will withstand the tension occurring during use. The containers must withstand the sterilisation conditions to which they will be submitted. The design of the container and the method of sterilisation chosen are such that all parts of the containers that may be in contact with the infusion are sterilised. The containers are impermeable to micro-organisms after closure. The containers are such that after filling they are resistant to damage from accidental freezing which may occur during transport of the final preparation. The containers are and remain sufficiently transparent to allow the appearance of the contents to be examined at any time, unless otherwise justified and authorised.

The empty containers display no defects that may lead to leakage and the filled and closed containers show no leakage.

For satisfactory storage of some preparations, the container has to be enclosed in a protective envelope. The initial evaluation of storage has then to be carried out using the container enclosed in the envelope.

TESTS

Solution S. *Use solution S within 4 h of preparation*. Fill a container to its nominal capacity with *water R* and close it, if possible using the usual means of closure; otherwise close using a sheet of pure aluminium. Heat in an autoclave so that a temperature of 121 ± 2 °C is reached within 20 min to 30 min and maintain at this temperature for 30 min. If heating at 121 °C leads to deterioration of the container, heat at 100 °C for 2 h.

Blank. Prepare a blank by heating *water R* in a borosilicate-glass flask closed by a sheet of pure aluminium at the temperature and for the time used for the preparation of solution S.

Appearance of solution S. Solution S is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To a volume of solution S corresponding to 4 per cent of the nominal capacity of the container add 0.1 ml of *phenolphthalein solution R*. The solution is colourless. Add 0.4 ml of *0.01 M sodium hydroxide*. The solution is pink. Add 0.8 ml of *0.01 M hydrochloric acid* and 0.1 ml of *methyl red solution R*. The solution is orange-red or red.

Absorbance (*2.2.25*). Measure the absorbance of solution S from 230 nm to 360 nm, using the blank (see solution S) as the compensation liquid. At these wavelengths, the absorbance is not greater than 0.20.

Reducing substances. To 20.0 ml of solution S add 1 ml of *dilute sulphuric acid R* and 20.0 ml of *0.002 M potassium permanganate*. Boil for 3 min. Cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a titration using 20.0 ml of the blank. The difference between the titration volumes is not greater than 1.5 ml.

Transparency. Fill a container previously used for the preparation of solution S with a volume equal to the nominal capacity of the primary opalescent suspension (*2.2.1*) diluted 1 in 200 for a container made from polyethylene or polypropylene and 1 in 400 for other containers. The cloudiness of the suspension is perceptible when viewed through the container and compared with a similar container filled with *water R*.

LABELLING

The label accompanying a batch of empty containers includes a statement of:

– the name and address of the manufacturer,
– a batch number which enables the history of the container and of the plastic material of which it is manufactured to be traced.

01/2008:30203

3.2.3. STERILE PLASTIC CONTAINERS FOR HUMAN BLOOD AND BLOOD COMPONENTS

Plastic containers for the collection, storage, processing and administration of blood and its components are manufactured from one or more polymers, if necessary with additives. The composition and the conditions of manufacture of the containers are registered by the appropriate competent authorities in accordance with the relevant national legislation and international agreements.

When the composition of the materials of the different parts of the containers correspond to the appropriate specifications, their quality is controlled by the methods indicated in those specifications (see *3.1. Materials used for the manufacture of containers* and subsections).

Materials other than those described in the Pharmacopoeia may be used provided that their composition is authorised by the competent authority and that the containers manufactured from them comply with the requirements prescribed for Sterile Plastic Containers for Human Blood and Blood Components.

In normal conditions of use the materials do not release monomers, or other substances, in amounts likely to be harmful nor do they lead to any abnormal modifications of the blood.

The containers may contain anticoagulant solutions, depending on their intended use, and are supplied sterile.

Each container is fitted with attachments suitable for the intended use. The container may be in the form of a single unit or the collecting container may be connected by one or more tubes to one or more secondary containers to allow separation of the blood components to be effected within a closed system.

The outlets are of a shape and size allowing for adequate connection of the container with the blood-giving equipment. The protective coverings on the blood-taking needle and on the appendages must be such as to ensure the maintenance of sterility. They must be easily removable but must be tamper-proof.

The capacity of the containers is related to the nominal capacity prescribed by the national authorities and to the appropriate volume of anticoagulant solution. The nominal capacity is the volume of blood to be collected in the container. The containers are of a shape such that when filled they may be centrifuged.

The containers are fitted with a suitable device for suspending or fixing which does not hinder the collection, storage, processing or administration of the blood.

The containers are enclosed in sealed, protective envelopes.

CHARACTERS

The container is sufficiently transparent to allow adequate visual examination of its contents before and after the taking of the blood and is sufficiently flexible to offer minimum resistance during filling and emptying under normal conditions of use. The container contains not more than 5 ml of air.

TESTS

Solution S_1. Fill the container with 100 ml of a sterile, pyrogen-free 9 g/l solution of *sodium chloride R*. Close the container and heat it in an autoclave so that the contents are maintained at 110 °C for 30 min.

If the container to be examined contains an anticoagulant solution, first empty it, rinse the container with 250 ml of *water for injections R* at 20 ± 1 °C and discard the rinsings.

Solution S_2. Introduce into the container a volume of *water for injections R* corresponding to the intended volume of anticoagulant solution. Close the container and heat it in an autoclave so that the contents are maintained at 110 °C for 30 min. After cooling, add sufficient *water for injections R* to fill the container to its nominal capacity.

If the container to be examined contains an anticoagulant solution, first empty it and rinse it as indicated above.

Resistance to centrifugation. Introduce into the container a volume of *water R*, acidified by the addition of 1 ml of *dilute hydrochloric acid R*, sufficient to fill it to its nominal capacity. Envelop the container with absorbent paper impregnated with a 1 in 5 dilution of *bromophenol blue solution R1* or other suitable indicator and then dried. Centrifuge at 5000 *g* for 10 min. No leakage perceptible on the indicator paper and no permanent distortion occur.

Resistance to stretch. Introduce into the container a volume of *water R*, acidified by the addition of 1 ml of *dilute hydrochloric acid R*, sufficient to fill it to its nominal capacity. Suspend the container by the suspending device at the opposite end from the blood-taking tube and apply along the axis of this tube an immediate force of 20 N (2.05 kgf). Maintain the traction for 5 s. Repeat the test with the force applied to each of the parts for filling and emptying. No break and no deterioration occur.

Leakage. Place the container which has been submitted to the stretch test between two plates covered with absorbent paper impregnated with a 1 in 5 dilution of *bromophenol blue solution R1* or other suitable indicator and then dried. Progressively apply force to the plates to press the container so that its internal pressure (i.e. the difference between the applied pressure and atmospheric pressure) reaches 67 kPa within 1 min. Maintain the pressure for 10 min. No signs of leakage are detectable on the indicator paper or at any point of attachment (seals, joints, etc.).

Vapour permeability. For a container containing an anticoagulant solution, fill with a volume of a 9 g/l solution of *sodium chloride R* equal to the volume of blood for which the container is intended.

For an empty container, fill with the same mixture of anticoagulant solution and sodium chloride solution. Close the container, weigh it and store it at 5 ± 1 °C in an atmosphere with a relative humidity of (50 ± 5) per cent for 21 days. At the end of this period the loss in mass is not greater than 1 per cent.

Emptying under pressure. Fill the container with a volume of *water R* at 5 ± 1 °C equal to the nominal capacity. Attach a transfusion set without an intravenous cannula to one of the connectors. Compress the container so as to maintain throughout the emptying an internal pressure (i.e the difference between the applied pressure and atmospheric pressure) of 40 kPa. The container empties in less than 2 min.

Speed of filling. Attach the container by means of the blood-taking tube fitted with the needle to a reservoir containing a suitable solution having a viscosity equal to that of blood, such as a 335 g/l solution of *sucrose R* at 37 °C. Maintain the internal pressure of the reservoir (i.e. the difference between the applied pressure and atmospheric pressure) at 9.3 kPa with the base of the reservoir and the upper part of the container at the same level. The volume of liquid which flows into the container in 8 min is not less than the nominal capacity of the container.

Resistance to temperature variations. Place the container in a suitable chamber having an initial temperature of 20 °C to 23 °C. Cool it rapidly in a deep-freeze to – 80 °C and maintain it at this temperature for 24 h. Raise the temperature to 50 °C and maintain for 12 h. Allow to cool to room temperature. The container complies with the tests for resistance to centrifugation, resistance to stretch, leakage, vapour permeability emptying under pressure and speed of filling prescribed above.

Transparency. Fill the empty container with a volume equal to its nominal capacity of the primary opalescent suspension (*2.2.1*) diluted so as to have an absorbance (*2.2.25*) at 640 nm of 0.37 to 0.43 (dilution factor about 1 in 16). The cloudiness of the suspension must be perceptible when viewed through the bag, as compared with a similar container filled with *water R*.

Extractable matter. Tests are carried out by methods designed to simulate as far as possible the conditions of contact between the container and its contents which occur in conditions of use.

The conditions of contact and the tests to be carried out on the eluates are prescribed, according to the nature of the constituent materials, in the particular requirements for each type of container.

Haemolytic effects in buffered systems

Stock buffer solution. Dissolve 90.0 g of *sodium chloride R*, 34.6 g of *disodium hydrogen phosphate R* and 2.43 g of *sodium dihydrogen phosphate R* in *water R* and dilute to 1000 ml with the same solvent.

Buffer solution A_0. To 30.0 ml of stock buffer solution add 10.0 ml of *water R*.

Buffer solution B_0. To 30.0 ml of stock buffer solution add 20.0 ml of *water R*.

Buffer solution C_0. To 15.0 ml of stock buffer solution add 85.0 ml of *water R*.

Introduce 1.4 ml of solution S_2 into each of three centrifuge tubes. To tube I add 0.1 ml of buffer solution A_0, to tube II add 0.1 ml of buffer solution B_0 and to tube III add 0.1 ml of buffer solution C_0. To each tube add 0.02 ml of fresh, heparinised human blood, mix well and warm on a water-bath at 30 ± 1 °C for 40 min. Use blood collected less than 3 h previously or blood collected into an anticoagulant citrate-phosphate-dextrose solution (CPD) less than 24 h previously.

Prepare three solutions containing, respectively:

3.0 ml of buffer solution A_0 and 12.0 ml of *water R* (solution A_1),

4.0 ml of buffer solution B_0 and 11.0 ml of *water R* (solution B_1),

4.75 ml of buffer solution B_0 and 10.25 ml of *water R* (solution C_1).

To tubes I, II and III add, respectively, 1.5 ml of solution A_1, 1.5 ml of solution B_1 and 1.5 ml of solution C_1. At the same time and in the same manner, prepare three other tubes, replacing solution S_2 by *water R*. Centrifuge simultaneously the tubes to be examined and the control tubes at exactly 2500 *g* in the same horizontal centrifuge for 5 min. After centrifuging, measure the absorbances (*2.2.25*) of the liquids at 540 nm using the stock buffer solution as compensation liquid. Calculate the haemolytic value as a percentage from the expression:

$$\frac{A_{exp}}{A_{100}} \times 100$$

A_{100} = absorbance of tube III,

A_{exp} = absorbance of tube I or II or of the corresponding control tubes.

The solution in tube I gives a haemolytic value not greater than 10 per cent and the haemolytic value of the solution in tube II does not differ by more than 10 per cent from that of the corresponding control tube.

Sterility (*2.6.1*). The containers comply with the test for sterility. Introduce aseptically into the container 100 ml of a sterile 9 g/l solution of sodium chloride and shake the container to ensure that the internal surfaces have been entirely wetted. Filter the contents of the container through a membrane filter and place the membrane in the appropriate culture medium, as prescribed in the test for sterility.

Pyrogens (*2.6.8*). Solution S_1 complies with the test for pyrogens. Inject 10 ml of the solution per kilogram of the rabbit's mass.

Abnormal toxicity (*2.6.9*). Solution S_1 complies with the test for abnormal toxicity. Inject 0.5 ml of the solution into each mouse.

PACKAGING

The containers are packed in protective envelopes.

On removal from its protective envelope the container shows no leakage and no growth of micro-organisms. The protective envelope is sufficiently robust to withstand normal handling.

The protective envelope is sealed in such a manner that it cannot be opened and re-closed without leaving visible traces that the seal has been broken.

LABELLING

The labelling complies with the relevant national legislation and international agreements. The label states:

– the name and address of the manufacturer,
– a batch number which enables the history of the container and of the plastic material of which it is manufactured to be traced.

A part of the label is reserved for:

– the statement of the blood group, the reference number and all other information required by national legislation or international agreements, and an empty space is provided for the insertion of supplementary labelling.

The label of the *protective envelope* or the *label* on the container, visible through the envelope, states:

– the expiry date,
– that, once withdrawn from its protective envelope, the container must be used within 10 days.

The ink or other substance used to print the labels or the writing must not diffuse into the plastic material of the container and must remain legible up to the time of use.

01/2008:30204

3.2.4. EMPTY STERILE CONTAINERS OF PLASTICISED POLY(VINYL CHLORIDE) FOR HUMAN BLOOD AND BLOOD COMPONENTS

Unless otherwise authorised as described under *Sterile Plastic Containers for Human Blood and Blood Components* (*3.2.3*), the nature and composition of the material from which the containers are made comply with the requirements for *Materials based on Plasticised Poly(vinyl chloride) for Containers for Human Blood and Blood Components and for Containers for aqueous solutions for intravenous infusion* (*3.1.1*).

TESTS

They comply with the tests prescribed for *Sterile Plastic Containers for Human Blood and Blood Components* (*3.2.3*) and with the following tests to detect extractable matter.

Reference solution. Heat *water for injections R* in a borosilicate-glass flask in an autoclave at 110 °C for 30 min.

Oxidisable substances. Immediately after preparation of solution S_2 (see *3.2.3*), transfer to a borosilicate-glass flask a quantity corresponding to 8 per cent of the nominal capacity of the container. At the same time, prepare a blank using an equal volume of the freshly prepared reference solution

in another borosilicate-glass flask. To each solution add 20.0 ml of *0.002 M potassium permanganate* and 1 ml of *dilute sulphuric acid R*. Allow to stand protected from light for 15 min. To each solution add 0.1 g of *potassium iodide R*. Allow to stand protected from light for 5 min and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. The difference between the two titrations is not more than 2.0 ml.

Acidity or alkalinity. To a volume of solution S_2 corresponding to 4 per cent of the nominal capacity of the container add 0.1 ml of *phenolphthalein solution R*. The solution remains colourless. Add 0.4 ml of *0.01 M sodium hydroxide*. The solution is pink. Add 0.8 ml of *0.01 M hydrochloric acid* and 0.1 ml of *methyl red solution R*. The solution is orange-red or red.

Chlorides (*2.4.4*). 15 ml of solution S_2 complies with the limit test for chlorides (0.4 ppm). Prepare the standard using a mixture of 1.2 ml of *chloride standard solution (5 ppm Cl) R* and 13.8 ml of *water R*.

Ammonium (*2.4.1*). Dilute 5 ml of solution S_2 to 14 ml with *water R*. The solution complies with the limit test for ammonium (2 ppm).

Residue on evaporation. Evaporate to dryness 100 ml of solution S_2 in a borosilicate-glass beaker of appropriate capacity, previously heated to 105 °C. Evaporate to dryness in the same conditions 100 ml of the reference solution (blank test). Dry to constant mass at 100 °C to 105 °C. The residue from solution S_2 weighs not more than 3 mg, allowing for the blank test.

Absorbance (*2.2.25*). Measure the absorbance of solution S_2 from 230 nm to 360 nm, using the reference solution as compensation liquid. At wavelengths from 230 nm to 250 nm, the absorbance is not greater than 0.30. At wavelengths from 251 nm to 360 nm, the absorbance is not greater than 0.10.

Extractable di(2-ethylhexyl) phthalate. Extraction solvent, *alcohol R* diluted with *water R* to have a relative density (*2.2.5*) of 0.9389 to 0.9395, measured with a pycnometer.

Stock solution. Dissolve 0.100 g of *di(2-ethylhexyl) phthalate R* in the extraction solvent and dilute to 100.0 ml with the same solvent.

Standard solutions

(a) Dilute 20.0 ml of stock solution to 100.0 ml with extraction solvent.

(b) Dilute 10.0 ml of stock solution to 100.0 ml with extraction solvent.

(c) Dilute 5.0 ml of stock solution to 100.0 ml with extraction solvent.

(d) Dilute 2.0 ml of stock solution to 100.0 ml with extraction solvent.

(e) Dilute 1.0 ml of stock solution to 100.0 ml with extraction solvent.

Measure the absorbances (*2.2.25*) of the standard solutions at the maximum at 272 nm, using the extraction solvent as compensation liquid and plot a curve of absorbance against the concentration of di(2-ethylhexyl) phthalate.

Extraction procedure. Using the donor tubing and the needle or adaptor, fill the empty container with a volume equal to half the nominal volume with the extraction solvent, previously heated to 37 °C in a well-stoppered flask. Expel the air completely from the container and seal the donor tube. Immerse the filled container in a horizontal position in a water-bath maintained at 37 ± 1 °C for 60 ± 1 min without shaking. Remove the container from the water-bath, invert it gently ten times and transfer the contents to a glass flask. Immediately measure the absorbance at the maximum at 272 nm, using the extraction solvent as compensation liquid.

Determine the concentration of di(2-ethylhexyl) phthalate in milligrams per 100 ml of extract from the calibration curve. The concentration does not exceed:

– 10 mg per 100 ml for containers of nominal volume greater than 300 ml but not greater than 500 ml;
– 13 mg per 100 ml for containers of nominal volume greater than 150 ml but not greater than 300 ml;
– 14 mg per 100 ml for containers of nominal volume up to 150 ml.

PACKAGING

See *Sterile Plastic Containers for Human Blood and Blood Components* (*3.2.3*).

LABELLING

See *Sterile Plastic Containers for Human Blood and Blood Components* (*3.2.3*).

01/2008:30205

3.2.5. STERILE CONTAINERS OF PLASTICISED POLY(VINYL CHLORIDE) FOR HUMAN BLOOD CONTAINING ANTICOAGULANT SOLUTION

Sterile plastic containers containing an anticoagulant solution complying with the monograph on *Anticoagulant and Preservative Solutions for Human Blood (0209)* are used for the collection, storage and administration of blood. Before filling they comply with the description and characters given under *Empty Sterile Containers of Plasticised Poly(vinyl chloride) for Human Blood and Blood Components* (*3.2.4*).

Unless otherwise authorised as described under *Sterile Plastic Containers for Human Blood and Blood Components* (*3.2.3*), the nature and composition of the material from which the containers are made should comply with the requirements prescribed for *Materials based on Plasticised Poly(vinyl chloride) for Containers for Human Blood and Blood Components and for containers for aqueous solutions for intravenous infusion* (*3.1.1*).

TESTS

They comply with the tests prescribed for *Sterile Plastic Containers for Human Blood and Blood Components* (*3.2.3*) and with the following tests to measure the volume of anticoagulant solution and to detect extractable matter.

Volume of anticoagulant solution. Empty the container, collecting the anticoagulant solution in a graduated cylinder. The volume does not differ by more than ± 10 per cent from the stated volume.

Spectrophotometric examination (*2.2.25*). Measure the absorbance of the anticoagulant solution from the container between 250 nm and 350 nm, using as the compensation liquid an anticoagulant solution of the same composition that has not been in contact with a plastic material. The absorbance at the maximum at 280 nm is not greater than 0.5.

Extractable di(2-ethylhexyl) phthalate. Carefully remove the anticoagulant solution by means of the flexible transfer tube. Using a funnel fitted to the tube, completely fill the

container with *water R*, leave in contact for 1 min squeezing the container gently, then empty completely. Repeat the rinsing.

The container, so emptied and rinsed, complies with the test for extractable di(2-ethylhexyl) phthalate prescribed for *Empty Sterile Plastic Containers of Plasticised Poly(vinyl chloride) for Human Blood and Blood Components* (*3.2.4*).

PACKAGING AND LABELLING

See *Sterile Plastic Containers for Human Blood and Blood Components* (*3.2.3*).

01/2008:30206

3.2.6. SETS FOR THE TRANSFUSION OF BLOOD AND BLOOD COMPONENTS

Sets for the transfusion of blood and blood components consist principally of plastic tubing to which are fitted the parts necessary to enable the set to be used for transfusion in the appropriate manner. Sets include a closure-piercing device, a blood filter, a drip chamber, a flow regulator, a Luer connector and, usually, a site that allows an injection to be made at the time of use. When the sets are to be used with containers requiring an air-filter, this may be incorporated in the closure-piercing device or a separate air-inlet device may be used. The chamber enclosing the blood filter, the drip chamber and the main tubing are transparent. The materials chosen and the design of the set are such as to ensure absence of haemolytic effects. The sets comply with current standards regarding dimensions and performance.

All parts of the set that may be in contact with blood and blood components are sterile and pyrogen-free. Each set is presented in an individual package that maintains the sterility of the contents. The sets are not to be re-sterilised or re-used.

Sets for the transfusion of blood and blood components are manufactured in accordance with the rules of good manufacturing practice for medical devices and any relevant national regulations.

TESTS

Carry out the tests on sterilised sets.

Solution S. Make a closed circulation system from three sets and a 300 ml borosilicate-glass vessel. Fit to the vessel a thermostat device that maintains the temperature of the liquid in the vessel at 37 ± 1 °C. Circulate 250 ml of *water for injections R* through the system in the direction used for transfusion for 2 h at a rate of 1 litre/h (for example using a peristaltic pump applied to as short a piece of suitable silicone tubing as possible). Collect the whole of the solution and allow to cool.

Appearance of solution S. Solution S is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 25 ml of solution S add 0.15 ml of *BRP indicator solution R*. Not more than 0.5 ml of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 25 ml of solution S add 0.2 ml of *methyl orange solution R*. Not more than 0.5 ml of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator.

Absorbance (*2.2.25*). Examined from 230 nm to 250 nm, solution S shows no absorbance greater than 0.30. Examined from 251 nm to 360 nm, solution S shows no absorbance greater than 0.15.

Ethylene oxide. If the label states that ethylene oxide has been used for sterilisation, the content of ethylene oxide, determined by the method prescribed below, is not greater than 10 ppm. Examine by gas chromatography (*2.2.28*).

The chromatographic procedure may be carried out using:

– a stainless steel column 1.5 m long and 6.4 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with *macrogol 1500 R* (3 g per 10 g),

– *helium for chromatography R* as the carrier gas at a flow rate of 20 ml/min,

– a flame-ionisation detector,

maintaining the temperature of the column at 40 °C, that of the injector at 100 °C and that of the detector at 150 °C. Verify the absence of peaks interfering with the ethylene oxide peak by carrying out the test using an unsterilised set or using a different chromatographic system such as:

– a stainless steel column 3 m long and 3.2 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with *triscyanoethoxypropane R* (2 g per 10 g),

— *helium for chromatography R* as the carrier gas at a flow rate of 20 ml/min,

– a flame-ionisation detector,

maintaining the temperature of the column at 60 °C, that of the injector at 100 °C and that of the detector at 150 °C.

Ethylene oxide solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *ethylene oxide R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *ethylene oxide R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject these 25 ml of ethylene oxide slowly into the vial, shaking gently and avoiding contact between the needle and the liquid. Weigh the vial again: the increase in mass is 45 mg to 60 mg and is used to calculate the exact concentration of the solution (about 1 g/l).

Test. Weigh the set after removing the package. Cut the set into pieces of maximum dimension 1 cm and place the pieces in a 250 ml to 500 ml vial containing 150 ml of *dimethylacetamide R*. Close the vial with a suitable stopper and secure the stopper. Place the vial in an oven at 70 ± 1 °C for 16 h. Remove 1 ml of the hot gas from the vial and inject it onto the column. From the calibration curve and the height of the peak obtained, calculate the mass of ethylene oxide in the vial.

Calibration curve. In a series of seven vials of the same type as that used for the test and each containing 150 ml of *dimethylacetamide R*, place respectively 0 ml, 0.05 ml, 0.10 ml, 0.20 ml, 0.50 ml, 1.00 ml and 2.00 ml of the ethylene oxide solution, i.e. about 0 µg, 50 µg, 100 µg, 200 µg, 500 µg, 1000 µg and 2000 µg of ethylene oxide. Stopper the vials, secure the stoppers and place the vials in an oven at 70 ± 1 °C for 16 h. Inject 1 ml of the hot gas from each vial onto the column and draw a calibration curve from the heights of the peaks and the mass of ethylene oxide in each flask.

Reducing substances. *Carry out the test within 4 h of preparation of solution S.* To 20.0 ml of solution S add 1 ml of *dilute sulphuric acid R* and 20.0 ml of *0.002 M potassium permanganate*. Boil for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate with *0.01 M sodium thiosulphate* using 0.25 ml of *starch solution R* as indicator.

Carry out a blank test using 20 ml of *water for injections R*. The difference between the titration volumes is not greater than 2.0 ml.

Extraneous particles. Fill the set via the normal inlet with a 0.1 g/l solution of *sodium laurilsulfate R*, previously filtered through a sintered-glass filter (16) (*2.1.2*) and heated to 37 °C. Collect the liquid via the normal outlet. When examined under suitable conditions of visibility, the liquid is clear and practically free from visible particles and filaments (it is assumed that particles and filaments with a diameter equal to or greater than 50 µm are visible to the naked eye).

Flow rate. Pass through a complete set with the flow regulator fully open 50 ml of a solution having a viscosity of 3 mPa·s (3 cP) (for example a 33 g/l solution of *macrogol 4000 R* at 20 °C) under a static head of 1 m. The time required for passage of 50 ml of the solution is not greater than 90 s.

Resistance to pressure. Make tight the extremities of the set and any air-inlet device. Connect the set to a compressed air outlet fitted with a pressure regulator. Immerse the set in a tank of water at 20 °C to 23 °C. Apply progressively an excess pressure of 100 kPa and maintain for 1 min. No air bubble escapes from the set.

Transparency. Use as reference suspension the primary opalescent suspension (*2.2.1*) diluted 1 in 8 for sets having tubing with an external diameter less than 5 mm and diluted 1 in 16 for sets having tubing with an external diameter of 5 mm or greater. Circulate the reference suspension through the set and compare with a set from the same batch filled with *water R*. The opalescence and presence of bubbles are discernible.

Residue on evaporation. Evaporate 50.0 ml of solution S to dryness on a water-bath and dry to constant mass in an oven at 100 °C to 105 °C. Carry out a blank test using 50.0 ml of *water for injections R*. The difference between the masses of the residues is not greater than 1.5 mg.

Sterility (*2.6.1*). The sets comply with the test for sterility. If the sets are stated to be sterile only internally, pass 50 ml of buffered sodium chloride-peptone solution pH 7.0 (*2.6.12*) through the set and use to carry out the test by the membrane-filtration method.

If the sets are stated to be sterile both internally and externally, open the package with the necessary aseptic precautions and:

– for the direct inoculation method, place the set or its components in a suitable container containing a sufficient quantity of the culture medium to ensure complete immersion;

– for the membrane filtration method, place the set or its components in a suitable container containing a sufficient quantity of buffered sodium chloride-peptone solution pH 7.0 (*2.6.12*) to allow total rinsing for 10 min.

Pyrogens (*2.6.8*). Connect together five sets and pass through the assembly at a flow rate not exceeding 10 ml/min 250 ml of a sterile, pyrogen-free 9 g/l solution of *sodium chloride R*. Collect the solution aseptically in a pyrogen-free container. The solution complies with the test for pyrogens. Inject 10 ml per kilogram of the rabbit's mass.

LABELLING

The label states, where applicable, that the set has been sterilised using ethylene oxide.

01/2008:30208

3.2.8. STERILE SINGLE-USE PLASTIC SYRINGES

Sterile single-use plastic syringes are medical devices intended for immediate use for the administration of injectable preparations. They are supplied sterile and pyrogen-free and are not to be re-sterilised or re-used. They consist of a syringe barrel and a piston which may have an elastomer sealing ring; they may be fitted with a needle which may be non-detachable. Each syringe is presented with individual protection for maintaining sterility.

The barrel of the syringe is sufficiently transparent to permit dosages to be read without difficulty and allow air bubbles and foreign particles to be discerned.

The plastics and elastomer materials of which the barrel and piston are made comply with the appropriate specification or with the requirements of the competent authority. The most commonly used materials are polypropylene and polyethylene. The syringes comply with current standards regarding dimensions and performance.

Silicone oil (*3.1.8*) may be applied to the internal wall of the barrel to assist in the smooth operation of the syringe but there remains no excess capable of contaminating the contents at the time of use.

The inks, glues and adhesives for the marking on the syringe or on the package and, where necessary, the assembly of the syringe and its package, do not migrate across the walls.

TESTS

Solution S. Prepare the solution in a manner that avoids contamination by foreign particles. Using a sufficient number of syringes to produce 50 ml of solution, fill the syringes to their nominal volume with *water for injections R* and maintain at 37 °C for 24 h. Combine the contents of the syringes in a suitable borosilicate-glass container.

Appearance of solution. Solution S is clear (*2.2.1*) and colourless (*2.2.2, Method II*) and is practically free from foreign solid particles.

Acidity or alkalinity. To 20 ml of solution S add 0.1 ml of *bromothymol blue solution R1*. Not more than 0.3 ml of *0.01 M sodium hydroxide* or *0.01 M hydrochloric acid* is required to change the colour of the indicator.

Absorbance (*2.2.25*). Measure the absorbance of solution S from 220 nm to 360 nm. The absorbance does not exceed 0.40.

Ethylene oxide. If the label states that ethylene oxide has been used for sterilisation, the content of ethylene oxide, determined by the method described below, is not greater than 10 ppm. Examine by gas chromatography (*2.2.28*).

The chromatographic procedure may be carried out using:

– a stainless steel column 1.5 m long and 6.4 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with *macrogol 1500 R* (3 g per 10 g),

– *helium for chromatography R* as the carrier gas at a flow rate of 20 ml/min,

– a flame-ionisation detector,

maintaining the temperature of the column at 40 °C, that of the injector at 100 °C and that of the detector at 150 °C. Verify the absence of peaks interfering with the ethylene oxide peak, either by carrying out the test using an unsterilised syringe or using a different chromatographic system such as:

– a stainless-steel column 3 m long and 3.2 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with *triscyanoethoxypropane R* (2 g per 10 g),

– *helium for chromatography R* as carrier gas at a flow rate of 20 ml/min,

– a flame-ionisation detector,

maintaining the temperature of the column at 60 °C, that of the injector at 100 °C and that of the detector at 150 °C.

Ethylene oxide solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *ethylene oxide R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *ethylene oxide R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject these 25 ml of ethylene oxide slowly into the vial, shaking gently and avoiding contact between the needle and the liquid. Weigh the vial again: the increase in mass is 45 mg to 60 mg and is used to calculate the exact concentration of the solution (about 1 g/l).

Calibration curve. In a series of seven vials of the same type as that used for the test and each containing 150 ml of *dimethylacetamide R*, place respectively 0 ml, 0.05 ml, 0.10 ml, 0.20 ml, 0.50 ml, 1.00 ml and 2.00 ml of the ethylene oxide solution, i.e. about 0 µg, 50 µg, 100 µg, 200 µg, 500 µg, 1000 µg and 2000 µg of ethylene oxide. Stopper the vials, secure the stoppers and place the vials in an oven at 70 ± 1 °C for 16 h. Inject 1 ml of the hot gas from each vial onto the column and draw a calibration curve from the heights of the peaks and the mass of ethylene oxide in each flask.

Test. Weigh the syringe after removing the package. Cut the syringe into pieces of maximum dimension 1 cm and place the pieces in a 250 ml to 500 ml vial containing 150 ml of *dimethylacetamide R*. Close the vial with a suitable stopper and secure the stopper. Place the vial in an oven at 70 ± 1 °C for 16 h. Remove 1 ml of the hot gas from the vial and inject it onto the column. From the calibration curve and the height of the peak obtained, calculate the mass of ethylene oxide in the vial.

Silicone oil. Calculate the internal surface area of a syringe in square centimetres using the expression:

$$2\sqrt{V \cdot \pi \cdot h}$$

V = nominal volume of the syringe, in cubic centimetres,

h = height of the graduation, in centimetres.

Take a sufficient number of syringes to give an internal surface area of 100 cm^2 to 200 cm^2. Aspirate into each syringe a volume of *methylene chloride R* equal to half the nominal volume and make up to the nominal volume with air. Rinse the internal surface corresponding to the nominal volume with the solvent by inverting the syringe ten times in succession with the needle fitting closed by a finger covered by a plastic film inert to methylene chloride. Expel the extracts into a tared dish and repeat the operation. Evaporate the combined extracts to dryness on a water-bath. Dry at 100 °C to 105 °C for 1 h. The residue weighs not more than 0.25 mg per square centimetre of internal surface area.

Examine the residue by infrared absorption spectrophotometry (*2.2.24*). It shows absorption bands typical of silicone oil at 805 cm^{-1}, 1020 cm^{-1}, 1095 cm^{-1}, 1260 cm^{-1} and 2960 cm^{-1}.

Reducing substances. To 20.0 ml of solution S add 2 ml of *sulphuric acid R* and 20.0 ml of *0.002 M potassium permanganate*. Boil for 3 min. Cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate* using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration using 20.0 ml of *water for injections R*. The difference between the titration volumes is not greater than 3.0 ml.

Transparency. Fill a syringe with *water R* (blank) and fill another with a 1 in 10 dilution of primary opalescent suspension (*2.2.1*). Use primary opalescent suspension that has been allowed to stand at 20 ± 2 °C for 24 h before use. Compare with the naked eye in diffused light against a dark background. The opalescence of the suspension is detectable when compared with the blank.

Sterility (*2.6.1*). *Syringes stated to be sterile comply with the test for sterility carried out as follows.* Using aseptic technique, open the package, withdraw the syringe, separate the components and place each in a suitable container containing sufficient culture media to cover the part completely. Use both the recommended media (*2.6.1*).

Syringes stated to be sterile only internally comply with the test for sterility carried out as follows. Use 50 ml of inoculation medium for each test syringe. Using aseptic technique, remove the needle protector and submerge the needle in the culture medium. Flush the syringe five times by withdrawing the plunger to its fullest extent.

Pyrogens (*2.6.8*). Syringes with a nominal volume equal to or greater than 15 ml comply with the test for pyrogens. Fill a minimum of three syringes to their nominal volume with a pyrogen-free 9 g/l solution of *sodium chloride R* and maintain at a temperature of 37 °C for 2 h. Combine the solutions aseptically in a pyrogen-free container and carry out the test immediately using for each rabbit 10 ml of the solution per kilogram of body mass.

LABELLING

The label on the *package* states:

– the batch number,

– a description of the syringe,

– that the syringe is for single-use only.

The label on the outer *package* states:

– the method of sterilisation,

– that the syringe is sterile or that it is sterile only internally,

– the identity of the manufacturer,

– that the syringe is not to be used if the packaging is damaged or the sterility protector is loose.

01/2008:30209
corrected 6.0

3.2.9. RUBBER CLOSURES FOR CONTAINERS FOR AQUEOUS PARENTERAL PREPARATIONS, FOR POWDERS AND FOR FREEZE-DRIED POWDERS
