PREFACE

The United States Pharmacopeia (USP) contains over 14,000 drugs, each of which is a specific chemical compound with a biological activity that is medically useful. Most of these drugs have been developed commercially by the international pharmaceutical industry and, as a consequence, are associated with one or more trade names. Several names are frequently assigned to drugs, mainly for marketing purposes. Drugs are often manufactured and sold under license agreements with the original developer and acquire new names at this stage. In addition to all these trivial names which may be associated with a drug, it will have several chemical names, developed according to rules of nomenclature, which allow precise identification of the chemical involved. As a result of these factors, drugs usually have a number of aliases; an average of 5–6 is typical and very commonly-used drugs such as aspirin can have well over 100 different names or synonyms. Further, when drugs are sold in combination an entirely new family of names is developed for the combination.

The abundance of names has resulted in confusion. The consumer seeking information often has only one trivial name, one used, for example in an advertisement, and this name contains no information on the makeup or the use of the drug. The chemical name is essential to the scientist but gives no hint of the trade name and thus the ownership, licensing situation or general level of use of the drug remain obscure to this investigator.

This book has been compiled as an attempt to bring some clarity to the situation. Some 10,000 representative drugs in common use are

described here. Every drug has been given an Entry Name and, within each drug category, entries are arranged alphabetically by that Name. The Entry Name is that most commonly used for the material and is usually the US Adopted Name, that is, the name under which the drug is listed in the USP.

From the 14,000+ drugs contained in the USP, some 5,000 are in routine use. All of these, plus an additional 5,000 or so, are described in Part I. Compounds whose therapeutic activity is either trivial or obscure have been omitted from the database.

Drugs: Synonyms and Properties is organized by therapeutic category, with each category presented in alphabetical order. Drugs that have distinct activities, for example, an antiarrhythmic agent with coronary vasodilator properties, are found in each of the appropriate sections (*Antiarrhythmics* and *Coronary Vasodilators*). There is thus some duplication throughout Part I. Most authorities identify between 200 and 300 therapeutic categories. Some trivial categories, such as antiseptics, are not covered here and, as a result, Part I has 199 drug categories. (Two other groups, *Spermaticides* and *Alcohol and Tobacco Deterrents*, which are not true therapeutic agents have been appended to Part I.) This organization allows the reader, at a glance, to determine the number of drugs available as well as the different chemical families which may be present in a specific category. It is interesting, for example, to see how the database, with 483 penicillin-based antibiotics, 318 antihypertensives and 135 tranquilizers, but only 68 drugs used to manage Parkinson's disease, tends to reflect first world society and its perceived needs. The increasing sophistication of pharmaceutical research may also be discerned in categories such as the 40 ACE Inhibitors or the 18 Histamine H₂ Receptor Antagonists.

Within each record, the drug described is associated with its Chemical Abstracts Service (CAS) Registry Number (RN) (see Part II, Index 1). The RN is assigned by the CAS with great care to prevent association of the same number to more than one compound and has proved to be a useful unique identifier. Different chemicals can have the same molecular formula or may share a trivial name synonym and the CAS RN is the only datum which uniquely identifies a chemical to the exclusion of all other chemicals. Each record also provides, as available, two other numeric identifiers for the chemical. These are the monograph number from the Twelfth Edition of the Merck Index and the European Inventory of Existing commercial Chemical Substances (EINECS) Number (see Part II, Index 2). The chemical name, molecular formula, and a list of trade names and synonyms are provided; the physical properties of each compound are described and the known biological activity and

acute toxicity are recorded (see Part II, Index 3). Finally, the manufacturers and suppliers of the drug are listed (see Part III).

Established drugs are assets which pharmaceutical companies trade with one another and also license to third parties, exclusively or otherwise. In addition, corporate mergers, which have become increasingly common in recent years, cause the actual identity of a company to become a variable. For these reasons, both the owner and the supplier(s) of any specific drug are often difficult to determine with precision and, in this book, an attempt has been made to identify suppliers. The owner, if distinct from the supplier, is also identified but in a number of cases, where this is unclear, the original patent holder is listed.

ACKNOWLEDGEMENTS

The Editor would like to acknowledge the expert research, data compilation and editorial work performed by Dr Ellen Zeman and the skilled programming performed by Dr Ju-yun Li which allowed for accurate formatting and typesetting of this book. Finally, I should like to acknowledge the expert assistance and continual support provided by my wife, Kay, without whom none of my deadlines would have been met.

HOW TO USE THIS BOOK

A typical record from this book is shown below. Each of the major items in the record is identified. A record, identified by its Entry Number, may be located with the help of the indexes in Part II.

The entire book is organized by Entry Number, with Part I broken down into therapeutic category.

The Names and Synonyms Index in Part II is the master. It allows the reader to use any name or synonym for a compound to learn the Entry Number and thus locate the entry of that material. The entry contains all the names and synonyms that have been used for that drug. The CAS

RN and the EINECS Number are also indexed in Part II. If the reader knows either of these Numbers, the appropriate index will lead to the relevant entry or entries.

GLOSSARY OF UNITS

Units are associated exclusively with the properties of the drugs described in the various records in *Drugs: Synonyms and Properties*.

Name	Description
Melting point	This is expressed, implicitly, in degrees Celsius. Thus 184° is given for 184°C. If any other temperature scale is used, it is identified.
Boiling point	This is also given, implicitly, in degrees Celsius. If any other temperature scale is used, it is identified. A value such as 124° implies 124°C at normal atmospheric pressure (nominally 760 mm of mercury). When other pressures are operative, they are noted, in mm Hg, as a subscript. Thus 124° _{0.5} implies a boiling point of 124°C at a pressure of 0.5 mm mercury.
Density	The density, d , of materials is given in g/ml. The measurement temperature, if available, is given as a superscript, the temperature of the water reference as a subscript. Thus d_4^{25} means density at 25° referenced to water at 4°. The specific gravity (sg or SG) is the ratio of the density to that of water and is thus unitless.

Name	Description
Ultra-violet absorption spectra	The wavelengths, λ_m in nm (nanometers = 10^{-7} meter) of uv maxima are given and the absorption is in most cases also cited. The absorption is cited as an ϵ value, an E value or an A value. The E value, as in $E_{1\text{ cm}}^{1\%}$ is the absorption given by a 1% solution in the a cell of pathlength 1 cm and the A value, as in $A_{1\text{ cm}}^{1\%}$ is the extinction value given by a 1% solution in a cell of pathlength of 1 cm. In general E and A are logs, and are thus smaller numbers (usually 1–100) than ϵ , which is generally between 1,000 and 150,000.
Optical rotation	The optical rotation, α , of compounds is given in degrees, with a cited temperature and wavelength, where available. Thus $[\alpha]_D$ means a rotation measured at the sodium D line (589 nm) and $[\alpha]^{25}$ means a rotation measured at 25° but at an unspecified wavelength. The common notation, $[\alpha]_D^{25}$, means a rotation measured at 25°C and at the D line of sodium (589 nm). The measured rotation depends upon the concentration of the solution and the nature of the solvent and both of these are cited, when available. Concentration is often given as c, the concentration in g/100 ml, and a full citation of rotation would be $[\alpha]_D^{25} = 60^\circ$ (c = 1.25, EtOH).
Acute toxicity	The toxicity data in <i>Drugs: Synonyms and Properties</i> refers to acute toxicity and is generally cited as an LD_{50} value. The LD_{50} value is the quantity of chemical that is lethal to 50% of the tested animals and is usually expressed as the dose in milligrams, per kilogram of the animal's body weight. The animal species is given, as is the administration route. Both of these are abbreviated, as in the table opposite.
